Rare in the population, and uncommon even among the deprived children in whom it is sought. The general-population prevalence is unknown, and the disorder appears genuinely rare; it develops in only a minority even of children who have suffered severe deprivation, which tells us that pathogenic care is necessary but far from sufficient and that other, still poorly understood factors decide which deprived child goes on to show the syndrome. Where a figure exists it comes from high-risk sampling: in low-income community populations in the United Kingdom the prevalence reaches **up to 2 per cent**. That single anchoring number should be read for what it is, an estimate from an enriched, deprived sample rather than a base rate for children at large, and its very scarcity is part of the teaching, because the clinician who expects to see the disorder often will over-diagnose ordinary sociability.

26.8 Comorbidity

The company it keeps points back to a shared failure of inhibition. In younger children and through middle childhood the disorder often co-occurs with attention-deficit/hyperactivity disorder and with the externalising disorders more broadly, a pattern that has been read as evidence of a shared deficit in **cognitive inhibitory control**: the same weak brake that fails to hold back the socially disinhibited approach may also underlie the broader disruptive picture. Autism spectrum disorder may also co-occur, which is one reason the criteria deliberately omit an autism exclusion. Alongside these, the conditions that travel with early neglect, cognitive and language delays and stereotypies, may be present as well, reflecting the deprivation the child has lived through rather than the attachment disorder as such. The co-occurring conditions are named here, not taught; each is owned by its own topic.

26.9 Differential diagnosis: distinguishing it from ADHD with social impulsivity

The local differential that the criteria themselves anticipate is with attention-deficit/hyperactivity disorder. A child with that disorder and prominent social impulsivity can approach strangers and act without the usual social caution, superficially resembling the disinhibited attachment picture. The separating principle is that this attachment disorder does not, of itself, involve difficulties with attention or hyperactivity: its abnormality is confined to the social, stranger-directed disinhibition, whereas the impulsive child's approach sits within a pervasive inattentive and overactive syndrome. When the full requirements for both are met, both may be diagnosed, and comorbidity is common rather than exceptional. The broader comparison of the attachment disorders with autism spectrum disorder is a distinct discrimination, owned by another topic in this chapter and cross-referring the Intellectual disability and autism spectrum disorder notes for autism itself.

> Carry this into the exam: a friendly, boundary-crossing child who will go off with a stranger, in the setting of a history of extremes of insufficient care, has the externalising attachment disorder, and unlike its withdrawn sibling it may persist even in a markedly improved home.

26.10 Course and prognosis: the persistence that defines the disorder

The prognostic signature is a stubborn independence from the quality of later care. Where the sibling attachment disorder tends to recede once a child is placed with an adequate, responsive caregiver, this disorder does not reliably follow the caregiving environment. Its outcome is only modestly associated with the quality of the post-neglect home, and in many cases the behaviour persists even after that environment has become markedly improved. A further dissociation sharpens the picture: the disorder has not been identified in children who first experience social neglect only after the age of 2 years, which points to a sensitive early window and suggests that the core deficit is not simply the current absence of an attachment relationship but something laid down early and carried forward. This is why the diagnosis is not merely a description of a child's present home but a statement about an enduring trait.

RULE **Good caregiving reliably rescues the withdrawn sibling; it does not reliably rescue this one.** The single most examined contrast between the two attachment disorders is prognostic. Reactive attachment disorder's signs typically fade with adequate care, whereas the disinhibited pattern frequently persists despite a markedly improved caregiving environment. Treat the persistence as the diagnostic and prognostic fingerprint of the disinhibited disorder.

AXIS OF CONTRAST	REACTIVE ATTACHMENT DISORDER (NAMED FOR COMPARISON)	DISINHIBITED SOCIAL ENGAGEMENT DISORDER (THIS TOPIC)
Core behaviour toward others	Emotionally withdrawn, rarely seeks or responds to comfort	Indiscriminately sociable, over-familiar with unfamiliar adults
Emotional direction	Internalising	Externalising, disinhibited
Relation to the attachment bond	Reflects an absent or grossly underdeveloped attachment	Can occur across attachments from disturbed to secure
Response to improved caregiving	Signs typically recede with adequate care	Often persists despite markedly improved care
Onset-age and autism-exclusion criteria	Both present in its criteria set	Neither present

The two attachment disorders share their pathogenic-care requirement but diverge on direction, on the role of the attachment bond, and above all on whether adequate care resolves them; the disinhibited disorder is named for comparison here and taught in full only in its own right.

26.11 Classification: ICD-11, and a material difference over onset

Both major systems recognise the disorder, but they do not define it identically. In ICD-11 it is coded **6B45** and requires, as its essential features, a history of grossly insufficient care together with a persistent, pervasive pattern of reduced or absent reticence in approaching unfamiliar adults. The examinable divergence lies in onset: the ICD-11 description states that the symptoms are evident before the age of 5 years, whereas the DSM criteria impose no onset-age requirement at all and set only the modest developmental-age floor discussed above. It is held apart from autism by the indiscriminately social, over-familiar approach, the opposite of autism's social withdrawal, and by the absence of autism's restricted and repetitive behaviours. The predecessor category in ICD-10 was Disinhibited Attachment Disorder of Childhood, coded F94.2, a label a candidate will still meet in older Indian records.

IN INDIA

Two things anchor the topic to Indian practice. First, most services still diagnose and code under ICD, so the operative labels are the current 6B45 and the legacy F94.2 that persists in older files, and the onset-before-five wording of the ICD description becomes clinically live for a child who presents late out of long institutional care. Second, the population in whom this disorder is realistically sought, children reared with severely limited opportunity to form selective attachments, maps directly onto childcare institutions and orphanage settings, which makes the pathogenic-care history the first thing to establish. The deprivation evidence and the management response, including the primacy of a stable and sensitive caregiver, are developed in the attachment-disorder management topic in this chapter and are not reproduced here.

9 months	up to 2%	12 months	6B45
MINIMUM DEVELOPMENTAL AGE	PREVALENCE, LOW-INCOME UK COMMUNITY SAMPLE	THRESHOLD FOR THE PERSISTENT SPECIFIER	ICD-11 CODE

27 · Differentiation of RAD and DSED from ASD

A severely neglected child and an autistic child can look strikingly alike across a clinic room, and telling them apart is the whole of these marks. A young child brought from an institution or a grossly depriving home may be socially odd, emotionally flat, poorly related and slow to speak, and the first diagnosis that comes to an inexperienced mind is autism. The task this topic sets is the disciplined separation of the two attachment disorders of childhood, **reactive attachment disorder** and **disinhibited social engagement disorder**, from **autism spectrum disorder**. The examiner is not testing whether you can define each condition; the criteria of the two attachment disorders are developed in their own right elsewhere in this chapter, and autism spectrum disorder is taught in full in the Intellectual disability and autism spectrum disorder notes. What is tested here is the reasoning that keeps a deprived child from being mislabelled autistic, and, just as importantly, that keeps a genuinely autistic child from having every deficit written off as the effect of a difficult early life.

The comparison runs along a small number of axes, and each of them cuts cleanly if it is asked properly: the history of care, the presence or near-absence of selective attachment, the quality of social communication, the presence or absence of a restricted and repetitive repertoire, and, decisively, what happens when the child is placed in a good environment. Hold those five questions in mind and the differential resolves; miss the history and it does not. This fragment teaches only the attachment-side view of the boundary. It names reactive attachment disorder and disinhibited social engagement disorder without re-teaching them, and it points to the Intellectual disability and autism spectrum disorder notes for autism spectrum disorder itself.

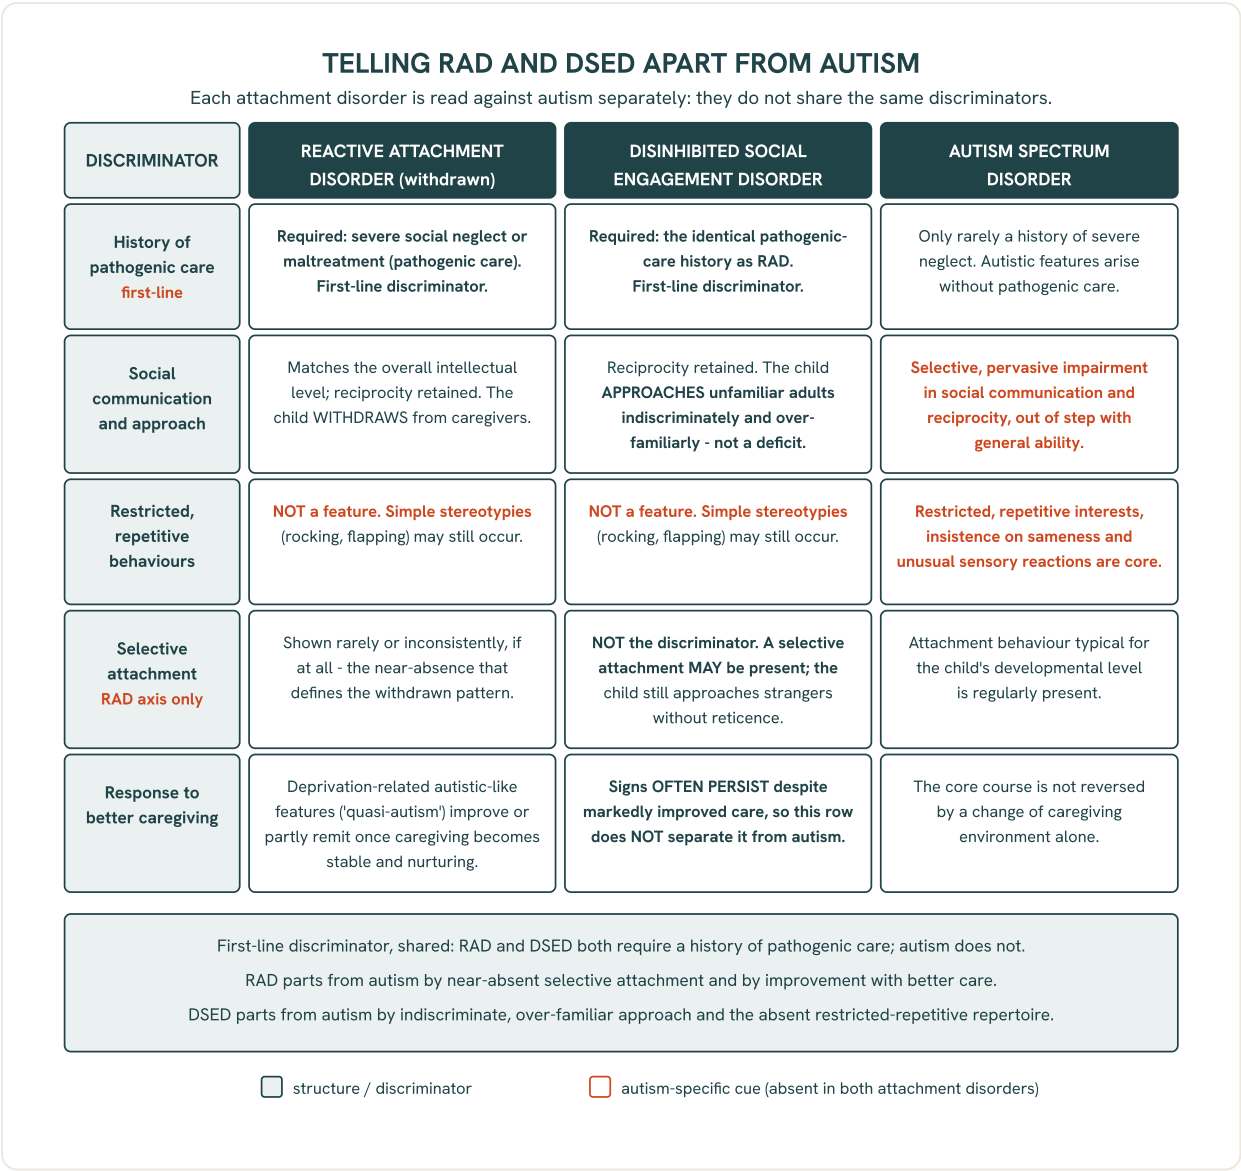

Fig 23.21. Telling reactive attachment disorder and disinhibited social engagement disorder apart from autism spectrum disorder, the attachment-side view, read separately for each disorder: the required history of pathogenic care is the first-line discriminator for both, while near-absent selective attachment and improvement of quasi-autistic features with better caregiving carry reactive attachment disorder, and indiscriminate, over-familiar social approach with preserved reciprocity carries the disinhibited disorder; the restricted-repetitive repertoire is absent in both; for autism spectrum disorder itself, see the Intellectual disability and autism spectrum disorder notes.

27.1 The required history of pathogenic care is the first-line discriminator

Begin with the history, because it is where the whole differential turns. The two attachment disorders are not free-standing behavioural pictures; each requires, as a diagnostic precondition, a documented **history of severe social neglect or maltreatment** - repeated changes of caregiver, institutional rearing, or a pattern of care that failed to meet the child's basic emotional needs. Autism spectrum disorder carries no such requirement and only rarely arrives with such a history. This asymmetry makes the care history the single most efficient opening question in the differential: an aberrant social presentation on a background of grossly inadequate care points first towards an attachment disorder, whereas the same presentation in a child whose early caregiving was adequate points away from it. The history does not, on its own, settle the diagnosis, because a maltreated child can also be autistic, but it sets the prior, and a candidate

who reaches for autism before taking the developmental and placement history has already made the classic mistake.

RULE **No pathogenic care, no attachment disorder; abundant pathogenic care, think of it first.** Reactive attachment disorder and disinhibited social engagement disorder both demand a history of grossly insufficient care as a precondition, while autism spectrum disorder does not. The care history is therefore the discriminator to establish before any other, and it reframes every social sign that follows.

27.2 Selective attachment behaviour: present in autism, scarce in reactive attachment disorder, beside the point in the disinhibited disorder

Autistic children do form attachments; the emotionally withdrawn attachment-disordered child largely does not. This is the point most candidates get backwards. Contrary to the old caricature of the autistic child as unattached, children with autism spectrum disorder regularly show **attachment behaviour typical for their developmental level** - they seek their parent when distressed, prefer familiar caregivers, and show the ordinary preferences of a bonded child, even if the social style around that bond is atypical. The child with reactive attachment disorder shows this selective, preferential attachment only rarely and inconsistently, if at all; the emotionally withdrawn pattern that defines that disorder is precisely a failure to turn to a discriminated attachment figure for comfort. Observing the child across separation and reunion, or simply watching whom the child goes to when hurt or frightened, is a practical way to elicit this contrast. The presence of developmentally expectable attachment is evidence for autism over reactive attachment disorder; its near-absence in a neglected child is evidence for the attachment disorder. Disinhibited social engagement disorder does not sit on this axis at all, and assuming that it does is the second reversal to avoid. The disinhibited child's difficulty is not a missing selective attachment but an indiscriminate, over-familiar approach to unfamiliar adults; such a child may hold an ordinary selective attachment to a caregiver and still go off with a stranger without reticence. Against autism, the disinhibited disorder is therefore separated by the direction and indiscriminateness of social approach, not by absent attachment.

27.3 Reciprocal social communication is selectively impaired only in autism

This is the axis that separates a delayed child from a deviant one. Autism is defined by a pervasive, selective deficit in **social-communicative behaviour** - impaired social reciprocity, deficits in non-verbal communication, and difficulty with relationships - that stands out against, and is disproportionate to, the child's general level of functioning. The child with reactive attachment disorder shows social communication that is broadly commensurate with their overall intellectual level: their language may be delayed by the deprivation itself, and their affect may be muted, but the capacity for reciprocal social interaction is retained rather than qualitatively deviant. In other words, the neglected child is often behind across the board, whereas the autistic child is specifically and disproportionately impaired in the social-communicative domain. The clinical move, therefore, is to ask whether the social deficit is out of step with the rest of development. If it is a selective peak of impairment, that favours autism; if the child's social relatedness tracks their general delay, that favours the attachment disorder. The disinhibited

disorder leaves reciprocal social communication intact in a way that is, if anything, more obvious: the disinhibited child approaches, talks to and engages unfamiliar adults readily and without reticence, which is the mirror image of the autistic child's reduced social approach and impaired reciprocity. Excessive, undiscriminating sociability is not a social-communication deficit, and it is the axis on which the disinhibited disorder parts from autism most cleanly.

27.4 The restricted, repetitive repertoire belongs to autism

The second pillar of autism is simply absent in the attachment disorders. Autism requires not only the social-communication deficit but a restricted, repetitive and inflexible repertoire. The **restricted interests and repetitive behaviours** that characterise autism are not a feature of reactive attachment disorder or disinhibited social engagement disorder. Concretely, what you look for and do not find in the pure attachment disorder is:

- excessive adherence to rituals and routines, with distress at small changes;
- restricted, fixated interests of abnormal intensity or focus;
- unusual sensory reactions - hyper- or hypo-reactivity to sounds, textures or lights.

A caveat prevents this axis from being used naively. Both attachment-disordered and institutionally reared children may show simple motor stereotypies such as body-rocking or hand-flapping, especially where stimulation has been sparse, and these can superficially mimic autistic mannerisms. A single stereotypy is not the restricted-repetitive-inflexible repertoire. What is specific to autism is the whole inflexible pattern - the insistence on sameness, the circumscribed interests and the sensory features together - not an isolated self-soothing movement that a barren environment has shaped.

27.5 Quasi-autism and the test of a nurturing environment

The clearest natural experiment in this whole differential is what a good home does to the picture. Some children reared under severe institutional deprivation develop a cluster of autistic-like features - difficulties in social reciprocity alongside restricted and repetitive behaviours - that is close enough to autism to be called **quasi-autism**. Here the static cross-sectional signs may genuinely overlap with autism, and the axes above can leave real doubt. The discriminator that does the work in these children is longitudinal, not cross-sectional: the deprivation-related picture shows significant improvement, or at least partial remission, when the child is moved into a stable, sensitive and nurturing environment, and that trajectory is what differentiates it from autism, in which the core features persist despite good caregiving. This is why placement in a good home is not only the treatment but part of the diagnostic test. A picture that lifts substantially with better care was never true autism; a picture that holds firm despite it is the real thing.

PITFALL

Overshadowing runs in both directions, and both are errors. The first is to see a socially odd, deprived child and diagnose autism at the first appointment, before the care history and before any period of stable placement has had a chance to reveal a reversible, quasi-autistic picture. The second, subtler, error is to assume that because a child was maltreated every deficit must be attachment-related, and so to miss a genuinely co-occurring autism that will not remit with a good home and needs autism-specific support in its own right. Neglect and autism can coexist; a maltreatment history does not exclude the neurodevelopmental diagnosis.

27.6 Bringing the axes together at the bedside

No single sign is pathognomonic; the diagnosis is the convergence of the axes plus the history plus the course. The efficient examination answer moves through the discriminators in order - the care history first, then attachment behaviour, then whether the social deficit is selective or part of a global delay, then the presence or absence of the restricted-repetitive repertoire, and finally the response to enhanced caregiving over time - and reads them together rather than trusting any one in isolation. Note which axes carry which disorder. The care history carries both attachment disorders. Absent selective attachment carries only reactive attachment disorder. The course axis carries reactive attachment disorder and quasi-autism, and it does not separate the disinhibited disorder from autism, because the signs of the disinhibited disorder often persist despite markedly improved care. What separates the disinhibited disorder from autism is the phenotype itself: an indiscriminate, over-familiar approach to strangers is the opposite of an autistic deficit in social approach and reciprocity, and the restricted, repetitive repertoire is absent. The accompanying figure lays out the same contrast so it can be recalled at a glance.

DISCRIMINATING AXIS	REACTIVE ATTACHMENT DISORDER	DISINHIBITED SOCIAL ENGAGEMENT DISORDER	AUTISM SPECTRUM DISORDER
History of care	Severe neglect or maltreatment required as a precondition	The same pathogenic-care history required	Only rarely a history of pathogenic care
Selective attachment	Rare, inconsistent or absent	Not the discriminator; a selective attachment may be present	Present and typical for developmental level
Social communication	Commensurate with overall intellectual level; capacity for reciprocity retained	Reciprocity retained; social approach is indiscriminate and overfamiliar rather than deficient	Selectively and disproportionately impaired
Restricted, repetitive repertoire	Not a feature; isolated stereotypies may occur	Not a feature; isolated stereotypies may occur	Present - rituals, fixated interests, sensory features
Course with a nurturing environment	Improves; deprivation-related features can remit	Signs often persist despite improved care; this axis does not discriminate it from autism	Core features persist despite good caregiving

The attachment-side comparison across the five axes that carry the differential, read separately for each attachment disorder; the care history discriminates both from autism, the attachment and course rows carry reactive attachment disorder, and the disinhibited disorder is separated from autism by indiscriminate social approach and the absent restricted-repetitive repertoire.

TRAP **Reversing the attachment axis.** The examination favourite is the belief that the autistic child is the one who cannot attach. It is the reactive attachment disorder child who fails to show selective attachment; the autistic child usually attaches to caregivers in a developmentally typical way. State the direction correctly and this half of the question is won.

Carry this into the exam: a required history of pathogenic care, plus improvement of autistic-like features once the child is in a stable and nurturing home, points to an attachment disorder or quasi-autism, not to autism spectrum disorder.

GOOD TO REMEMBER

Do not force the diagnosis at a single visit for the deprived, socially atypical young child. Establish the care history, observe selective attachment directly through separation and reunion, judge whether the social deficit is selective or part of a global delay, and then let time in a stable placement do its diagnostic work. If the picture lifts with good care, it was on the attachment-and-deprivation side; if it holds firm, take the autism diagnosis seriously and arrange autism-specific assessment and support.

IN INDIA

The differential is unusually live in Indian practice because institutional and multiply-disrupted care is not rare: children present from orphanages, children's homes and severely deprived family settings, and many are seen first around adoption or foster placement. Two practical points follow. Most services diagnose under ICD, which frames both the attachment disorders and the quasi-autism boundary, and this favours a longitudinal view - reassessing after the child has spent time in a settled home rather than fixing an autism label at intake. And because language delay in these children so often reflects deprivation and a multilingual environment rather than a communication disorder, the social-communication axis must be judged against the child's whole developmental level, not against a single clinic-room silence. The full assessment battery and the services and protection pathways for such children sit in the Child psychiatry: assessment, treatment, services and protection notes.

History	Attachment	Repertoire	Course
SEVERE NEGLECT REQUIRED IN THE ATTACHMENT DISORDERS, ONLY RARELY PRESENT IN AUTISM	DEVELOPMENTALLY TYPICAL IN AUTISM, SCARCE IN REACTIVE ATTACHMENT DISORDER	RESTRICTED AND REPETITIVE ONLY IN AUTISM, NOT IN THE ATTACHMENT DISORDERS	QUASI-AUTISM IMPROVES WITH A NURTURING HOME; AUTISM PERSISTS

28 · Management of attachment disorders and effects of institutional care

This is the one childhood disorder whose treatment is a person, not a prescription. The two attachment disorders of early childhood, the emotionally withdrawn reactive attachment disorder and the indiscriminately sociable disinhibited social engagement disorder, both arise from the same soil: grossly insufficient care in the years when a child should be forming a selective attachment to one or two committed adults. Those two syndromes are described in full in their own right elsewhere in this chapter; what this topic owns is the ground beneath them - the effects of institutional rearing and early deprivation - and the management that follows from it. The marks here are conceptual and safety-critical at once. An examiner is checking that you understand the intervention is psychosocial and relational rather than pharmacological, that the two disorders respond differently to a good caregiver, and that the coercive "attachment therapies" sometimes marketed to desperate families are not merely unproven but have killed children.

The etiological premise is a form of **pathogenic care**: care so deficient, or so repeatedly interrupted, that the child never has the stable, responsive adult a secure attachment requires. Institutional rearing is the purest natural model of this, and it is why the entire evidence base rests on children raised in institutions and then placed in families. The requirement that pathogenic care precede the diagnosis is the etiological context the two disorder sections depend on; here it is the starting point for everything that follows.

28.1 The rearing that produces the two patterns

Two divergent behaviour sets emerge from the same deprivation. The observational basis for the modern classification is old and instructive. In **Barbara Tizard**'s study of institution-reared children whose caregivers had been explicitly instructed not to form attachments with them, of

26 such children, 8 nonetheless formed secure attachments, 8 were emotionally withdrawn and unresponsive in the pattern we now call reactive attachment disorder, and 10 were indiscriminately social with unfamiliar adults in the pattern we now call disinhibited social engagement disorder. Earlier still, Rene Spitz's descriptions of anaclitic depression in institutionalised infants foreshadowed the withdrawn phenotype. The lesson embedded in those numbers is that deprivation is a probabilistic exposure, not a deterministic one: even under an instruction not to bond, roughly a third of the children found an attachment anyway, which is the first clue that resilience and the availability of even one responsive adult matter enormously.

28.2 Timing and dose: the developmental window

The longer and the earlier the deprivation, the greater the harm. Risk is graded by both the duration of deprivation and the age at which it occurs. Attachment disorders are very rare in children adopted **before 6 months** of age, and signs of disinhibited social engagement have not been reported in children whose deprivation began only after the age of two years, marking a sensitive early period during which the developing attachment system is most vulnerable. Brief institutional care leaves children resembling their never-institutionalised comparison groups on most measures, and the neurophysiological differences seen in deprived children are no longer detectable at age eight if the child is placed with a family before twenty-four months. Yet the potency of prolonged deprivation is sobering: only **about 15%** of children adopted after at least six months of institutional rearing in Romania were free of any diagnosable disorder at any point into their mid-twenties.

- duration of deprivation - the longer the child lives in it, the more likely the disorders;
- age at onset - the early months carry a sensitive window, and disinhibited signs are tied to deprivation that begins early;
- age at placement - earlier rescue is associated with greater reversibility of the measurable deficits.

28.3 The natural experiment: the two disorders diverge under a good caregiver

Foster care turned into a randomised trial is what proves the point. The strongest evidence comes from the **Bucharest Early Intervention Project**, a prospective randomised controlled trial of high-quality foster care as an alternative to continued institutional care. Children with reactive attachment disorder randomised to foster families showed a reduction in symptoms within months of placement, falling to the levels of a community sample of never-institutionalised children. Children with disinhibited social engagement disorder in the same trial continued to show behaviours consistent with the diagnosis after placement, typically improving but not fully resolving. The **English and Romanian Adoptees study** converges on the same split: Romanian children adopted into English families no longer manifest reactive attachment disorder but continue to show persistent signs of disinhibited social engagement. The interpretation is the heart of the topic. Reactive attachment disorder behaves like a condition of missing attachment, so it lifts once a real attachment forms; disinhibited social engagement

behaves like something more enduring, whose core deficit is not simply the absence of an attachment relationship.

AXIS	REACTIVE ATTACHMENT DISORDER	DISINHIBITED SOCIAL ENGAGEMENT DISORDER
Response to a stable, sensitive caregiver	Symptoms reduce toward those of never-institutionalised community children	Signs reduce but commonly persist rather than resolve
Persistence after adoption	Does not continue once an attachment forms	Can persist in a minority even after attachments to the new family form
What this implies about the deficit	Essentially a lack-of-attachment state, remediable by the relationship	Not reducible to a missing attachment; a more enduring social-behavioural disturbance

The two disorders share a cause but not a prognosis under treatment; the differential response to a good caregiver is itself diagnostic teaching.

TRAP **Assuming both disorders remit fully once the child is placed in a loving home.** They do not. Reactive attachment disorder largely resolves with a positive caregiving environment, but disinhibited social engagement signs frequently persist even after the child has clearly formed attachments to the new caregivers. A candidate who writes that placement cures both has missed the single most examined discrimination in this topic.

28.4 The long reach of early deprivation

The effects outlast childhood and broaden well beyond attachment. Follow-up of the English and Romanian adoptees into **early adulthood, at ages 22 to 25**, found that those with longer institutional care before adoption had lower educational achievement, higher unemployment, and greater use of mental-health services. Prolonged deprivation was also associated with high rates of attention-deficit and autistic-type features and of callous-unemotional traits, and self-reported emotional symptoms actually rose from adolescence into adulthood rather than fading. This tells the clinician that institutional deprivation is not a narrow attachment problem but a broad neurodevelopmental and psychiatric risk exposure, and that some of its consequences declare themselves only years after the child is safe and settled. Where a deprived child later carries attention or behavioural difficulties, those are treated on their own terms; the treatment of the general attention-deficit disorder and its medication is the ADHD and specific learning/communication disorders notes'.

PITFALL

The recurring clinical error is to attribute every later difficulty in a post-institutional child to "attachment", and so to miss a comorbid, treatable disorder. A previously deprived child with genuine attention-deficit hyperactivity or autistic features needs that condition assessed and managed directly, not reframed as an attachment wound. Over-psychologising the history leaves an eminently treatable comorbidity untreated.

28.5 Management, first principle: secure the child's safety

Nothing else begins until the child is safe. Because these disorders arise from maltreatment or grossly deficient care, the first step of management is to assess and secure the child's safety, which includes medical referral for the consequences of neglect, involvement of child protective services where warranted, and an assessment of parental fitness. This is not bureaucratic sequencing: child maltreatment carries significant morbidity and non-trivial mortality, particularly in the youngest children, so establishing safety is genuinely the intervention that comes before all others. Only once safety is established does full attention turn to the psychosocial work of building an attachment.

IN INDIA

Institutional rearing remains a live reality here, with large numbers of children in child-care institutions, and national policy increasingly favours family-based alternatives - kinship care, foster care and adoption - over long-term institutionalisation. The statutory machinery for protection and placement is not taught here; that framework belongs to the Child psychiatry: assessment, treatment, services and protection notes. Two cautions for the exam. First, no Indian general-population prevalence figure for either attachment disorder is established, so quote none: the evidence base is Western institutional and adoption cohorts. Second, the same policy shift the evidence supports, moving children out of institutions and into responsive families, is exactly what the Romanian and English data would predict helps most.

28.6 The core intervention: a stable, sensitive caregiver

Everything effective in this topic reduces to one relationship. The central, evidence-informed intervention for both disorders is to provide and support a primary attachment figure who is sensitively responsive, who values the child as an individual, and who places the child's needs ahead of their own. For reactive attachment disorder this is frequently sufficient in itself: the symptoms generally resolve once the child is in a family that offers a genuinely positive caregiving environment. For disinhibited social engagement disorder, clinical consensus adds a further, face-valid but formally unevaluated measure - limiting the child's unnecessary contact with unfamiliar adults for several months so that a selective attachment to the new caregivers has room to consolidate before the child's sociability is diffused across everyone they meet.

RULE **The treatment is a committed, sensitive caregiver, and the relationship itself is the active ingredient.** Interventions work to the extent that they install and support one responsive adult who consistently reads and meets the child's needs; techniques that do not serve that end do not treat the disorder. This is why placement quality, not any specific therapy, is the strongest lever available.

GOOD TO REMEMBER

Once the child is safe, the most powerful thing a clinician can arrange is stability of caregiving - one committed adult, protected from disruption and repeated moves, over a long horizon. Placement breakdown and a revolving door of carers reproduce the original injury. Supporting the caregiver so the placement holds is itself the treatment, not a preliminary to it.

28.7 Dyadic therapies, medication, and the interventions to refuse

Add structured dyadic work, keep medication in its lane, and never coerce. Where more than placement is needed, the attachment-specific treatments focus on the **adult-child dyad** and include the Circle of Security, Attachment and Biobehavioral Catch-Up, and child-parent psychotherapy. These combine developmental guidance with review of videotaped parent-child interaction and attend to instrumental problems such as housing and medical care; long-term intervention is often necessary. Pharmacotherapy has no role in the core attachment disorder itself: the standard account describes management as entirely psychosocial, and no medication is directed at reactive attachment disorder or disinhibited social engagement disorder as such, with any drug treatment reserved for a co-occurring condition rather than the attachment disorder. Finally, the discriminating clinician must actively refuse a category of harm: the **coercive "attachment therapies"** - holding and restraint procedures, "rebirthing" and the like - are discredited by the 2016 practice parameters of the American Academy of Child and Adolescent Psychiatry and have caused the deaths of children. Management is the sensitive-caregiver and dyadic model, never coercion.

MNEMONIC

Secure, Attach, Support, Refuse

Secure the child's safety first; build the primary **A**ttachment through one sensitive caregiver; **S**upport that dyad with manualised therapy and treat comorbidity only; **R**efuse coercive holding and restraint "therapies" outright.

The active treatment is a stable, sensitively responsive caregiver: reactive attachment disorder largely resolves with it, disinhibited social engagement disorder only partly, medication treats only comorbidity, and coercive holding therapies are never used and have killed children.

Tic disorders and Tourette syndrome

29 · Classification of tic disorders (transient, chronic, Tourette)

Classification here is made almost entirely by the clock. A child brought in for repetitive blinking, sniffing or throat-clearing does not arrive with a diagnosis attached; what turns a description of movements into one of several named disorders is a small set of rules about how long the tics have lasted, whether they are motor, vocal or both, and whether an earlier tic diagnosis has already been made. Those rules are worth a disproportionate share of the marks,

because they are simple to state, easy to half-remember, and endlessly examinable: a single-word change, "and" to "or" or "less than" to "more than", moves the child from one diagnosis to another.

This section owns the classificatory scaffold: what counts as a tic at all, how simple tics are separated from complex ones, the full set of diagnostic categories, the duration and modality rules that divide them, the type specifier, and the hierarchy that governs which label a child may hold. The full diagnostic criteria and phenomenology of Tourette's disorder, the neurobiology, the comorbidity pattern with attention-deficit/hyperactivity disorder and obsessive-compulsive disorder, the management of tics, and the differentiation of tics from other abnormal movements are each developed in their own right elsewhere in this chapter; here they are named where the classification touches them, not reopened.

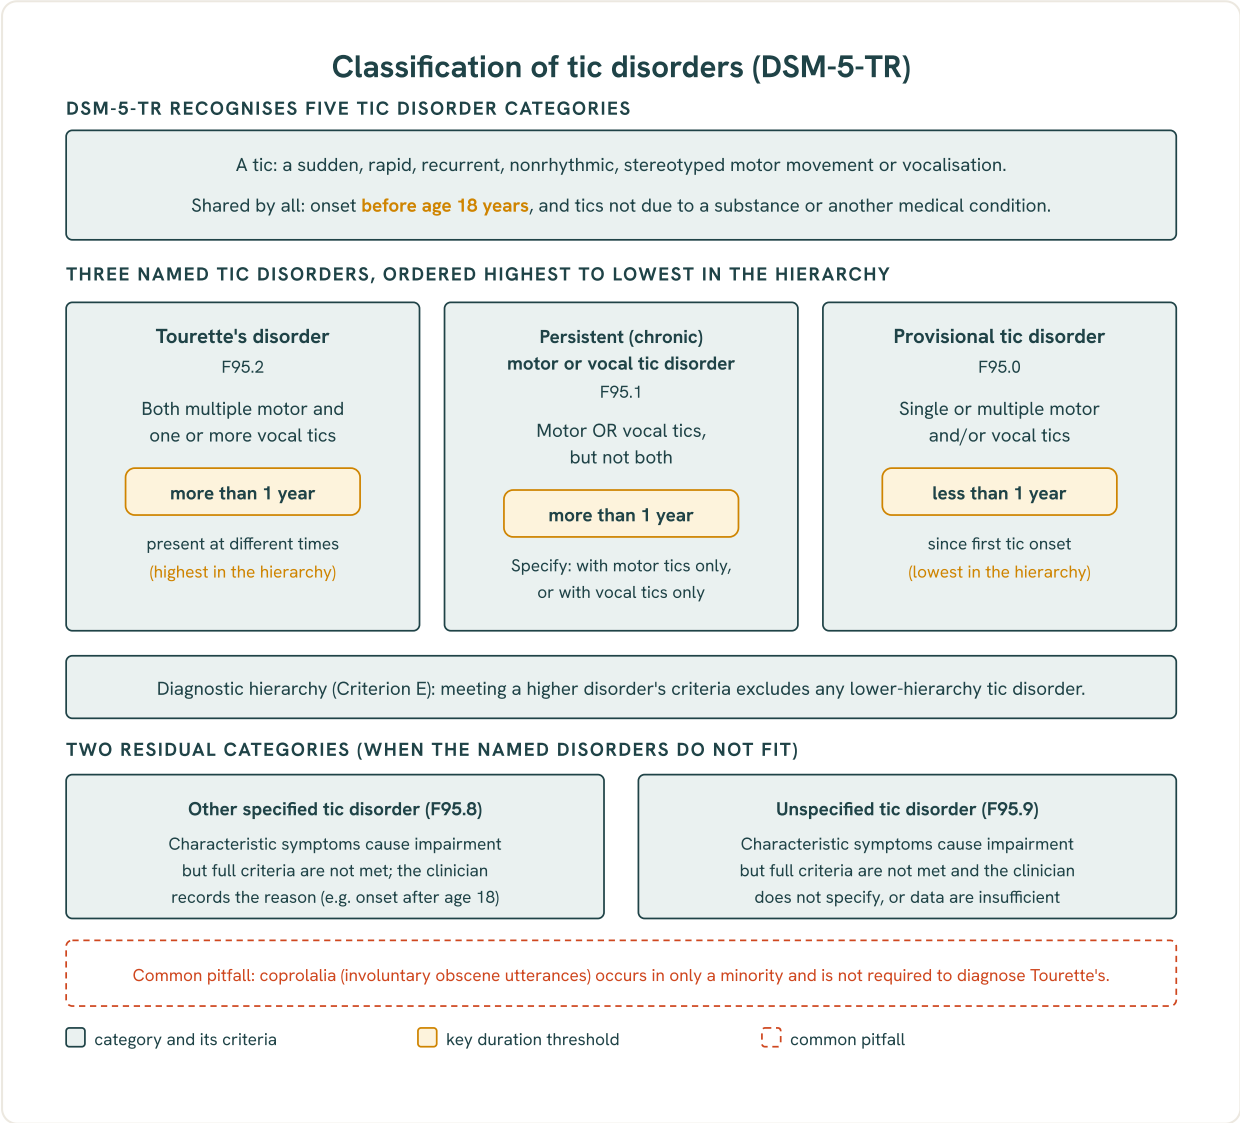

Fig 23.22. Classification of tic disorders: the three named DSM-5-TR disorders ordered by hierarchy - Tourette's disorder (both motor and vocal tics), persistent (chronic) motor or vocal tic disorder, and provisional tic disorder (less than 1 year) - together with the two residual categories and the coprolalia pitfall.

29.1 What counts as a tic

Everything downstream rests on one definition. A **tic** is a sudden, rapid, recurrent, nonrhythmic, stereotyped motor movement or vocalisation. Each word does work. *Sudden* and *rapid* mark the tic as fast and abrupt, unlike the slow writhing of a dystonic movement; *recurrent*

and *stereotyped* capture that the same movement repeats in a fixed form; *nonrhythmic* separates it from tremor, which is regular and oscillatory. The same definition covers both the motor and the vocal forms: a vocal tic is simply a tic whose effector is the respiratory and laryngeal apparatus, which is why a sniff, a grunt or a throat-clear is classified alongside a blink or a shrug rather than treated as something categorically different. Two further features, which sit in the phenomenology rather than the bare definition, make tics recognisable at the bedside and are developed with the Tourette phenomenology elsewhere in this chapter: tics are typically preceded by an uncomfortable premonitory urge and are, for a time, voluntarily suppressible. Naming them here is enough; the classification does not turn on them.

29.2 Simple and complex tics, and the taboo phenomena

Within both the motor and vocal channels, tics run from the fragmentary to the orchestrated. **Simple tics** are brief and meaningless: simple motor tics such as eye-blinks, facial grimaces and shoulder shrugs, and simple vocal tics such as throat-clearing, sniffing and grunting. **Complex tics** are longer, more elaborate and can look purposeful, which is exactly what makes them hard to read: complex motor tics include echopraxia (imitating another's movements) and copropraxia (obscene gestures), and complex vocal tics include palilalia, echolalia and coprolalia. The three "-lalia" terms are constantly confused and constantly examined, so fix them: **echolalia** is repeating the last word or sound one has just heard, **palilalia** is repeating one's own sounds or words, and **coprolalia** is the involuntary uttering of obscene or taboo words. Coprolalia is the feature the public most associates with Tourette's, and that association is the source of the single most common misconception in the topic, because it is present in only a minority and is required for no tic diagnosis at all.

TRAP **Coprolalia is neither necessary nor common.** The examination reflex, and the lay assumption, is that a diagnosis of Tourette's requires the patient to swear involuntarily. It does not. Coprolalia appears in only a minority of those affected and is a feature of no tic disorder's criteria. A candidate who makes coprolalia a requirement, or who withholds a tic diagnosis because it is absent, has mistaken a striking piece of phenomenology for the definition.

29.3 The diagnostic categories, and the logic that orders them

One organising idea makes the whole scheme memorable. The current DSM-5-TR classification recognises **five** tic-disorder categories: Tourette's disorder; persistent (chronic) motor or vocal tic disorder; provisional tic disorder; and the two residual categories, other specified and unspecified tic disorder. Which of the first three a child receives is decided by three things: the duration of the tics, their modality (motor, vocal or both), and whether an earlier tic diagnosis has already been made. Duration draws the line between the short-lived and the persistent; modality draws the line between the single-channel disorder and Tourette's; and the diagnostic history, through the hierarchy rule, prevents a child from sliding down into a lesser label. Hold that trio and the categories almost derive themselves; memorise the boxes without the logic and they blur together in exactly the way examiners rely on.

MNEMONIC

Time, then modality, then history

Read the three deciding questions in order. **Time:** have the tics lasted under a year or beyond it? Under a year and the label is provisional; beyond it and the disorder is one of the persistent forms. **Modality:** among the persistent forms, is only one channel involved, or are both? One channel is persistent (chronic) motor or vocal tic disorder; both is Tourette's. **History:** the hierarchy then forbids demoting a child who already qualifies for a higher category. Three questions, in that order, and every case lands in exactly one box.

29.4 Provisional tic disorder: the transient category

This is the diagnosis for tics that have not yet earned a chronic label. Provisional tic disorder is diagnosed when a child has single or multiple motor and/or vocal tics that have been present for **less than a year** since the first tic appeared, with onset in childhood, not attributable to a substance or another medical condition, and in a child who has never met criteria for Tourette's or a persistent tic disorder. The word "provisional" is deliberately provisional: at diagnosis one cannot know whether the tics will fade in a few months, as most childhood tics do, or persist past the year and convert the diagnosis into a chronic one. The older literature, and current Indian practice, call this same picture *transient tic disorder*, and the change of name matters: "transient" pre-judged an outcome knowable only in retrospect, whereas "provisional" states honestly that the diagnosis is held pending the passage of time. The motor-only or vocal-only specifier is not applied here; that distinction belongs only to the persistent disorder.

29.5 Persistent (chronic) motor or vocal tic disorder, and its specifier

The defining move here is the exclusive "or". Persistent (chronic) motor or vocal tic disorder is diagnosed when a child has had tics of one modality only, motor tics or vocal tics but not both, which may wax and wane in severity yet have persisted for **more than a year** since the first tic, again with childhood onset, not due to a substance or medical condition, and in a child who has never met criteria for Tourette's. The most consequential words in the whole classification are that "not both": the presence of even one vocal tic in a child who also has motor tics, once the year has passed, moves the diagnosis out of this category and into Tourette's. Because the disorder is restricted to one channel, it carries a required **type specifier**, either "with motor tics only" or "with vocal tics only", recording which channel is involved. That specifier exists only here; it is meaningless for Tourette's, where both channels are present by definition, and for the provisional disorder, where the picture is still unsettled.

29.6 Tourette's disorder at the apex

Tourette's is the category defined by the presence of both channels. Tourette's disorder sits at the top of the tic-disorder classification, and the feature that places it there is the requirement for both multiple motor tics and at least one vocal tic over the course of the illness, though the two need not be present at the same time. That both-modalities rule is the whole of what the classification needs from Tourette's; the full criteria, the characteristic waxing-and-waning course, the premonitory urge and the rest of the phenomenology are developed in their own right

elsewhere in this chapter and are not restated here. What matters for classification is the contrast with the category beneath it: where the persistent motor or vocal tic disorder is single-channel by rule, Tourette's is dual-channel by rule, and a child accrues the Tourette's label the moment both a motor and a vocal tic have been present over the required span of time. The coprolalia the public expects plays no part in this; a child with only simple motor and vocal tics and no obscene utterance whatsoever still has Tourette's once both channels and the duration are satisfied.

29.7 The diagnostic hierarchy and the one-way rule

The categories are not a menu; they are a ladder. The tic-disorder diagnoses are **hierarchical**, running from Tourette's at the top, through persistent (chronic) motor or vocal tic disorder, to provisional tic disorder, with the two residual categories beneath. The operative rule, written into each disorder's criteria as its exclusion clause, is that once a child has ever met criteria for a disorder higher in the hierarchy, a lower diagnosis can no longer be made. A child who has qualified for Tourette's cannot later be re-labelled with a persistent single-channel disorder simply because, at one review, only motor tics happen to be active; the higher diagnosis, once earned, holds. This is why the diagnostic history is the third deciding question and not an afterthought: the classification is cumulative and one-directional, and it deliberately resists the temptation to downgrade a child to a milder-sounding label during a quiet spell.

RULE **Duration and modality assign the category; the hierarchy protects it.** Under a year of tics is provisional; beyond a year it is one of the persistent forms; one channel among those is persistent motor or vocal tic disorder and both channels is Tourette's. The hierarchy then adds a one-way lock: a diagnosis once met at a higher level cannot be exchanged for a lower one. Every genuinely difficult classification question in this topic is testing one of those two mechanisms.

29.8 The residual categories, the whole scheme in one view, and the boundaries

The two residual categories catch what the specific ones cannot. Other specified tic disorder is used when a tic presentation causes clinically significant distress or impairment but does not meet the full criteria for any specific tic disorder, and the clinician chooses to record the particular reason (for example an onset after the childhood window). Unspecified tic disorder is used for the same sub-threshold situation when the clinician does not state the reason, or when there is insufficient information to do so. Both exist so that a real, impairing tic problem that sits outside the neat boxes still has a home in the record rather than being forced into a category it does not fit.

CATEGORY	TICS REQUIRED	DURATION	TYPE SPECIFIER
Provisional tic disorder	Motor and/or vocal	Less than a year	Not applied
Persistent (chronic) motor or vocal tic disorder	Motor *or* vocal, not both	More than a year	Motor only / vocal only
Tourette's disorder	Both motor and vocal	Long-standing	Not applied
Other specified / unspecified	Sub-threshold or atypical	Any	Not applied

The three specific categories read across duration and modality, with the residual pair holding the sub-threshold and atypical presentations; the accompanying figure lays the same decision out as its three ordered questions.

Two boundaries complete the picture without belonging to the classification proper. The first is with the other abnormal movements a tic must be told apart from before it even enters this scheme, because only a genuine tic is classified at all. The discriminating features are developed in their own right elsewhere in this chapter; here they are simply named:

- the stereotypies of stereotypic movement disorder and of autism spectrum disorder;
- chorea and the other hyperkinetic movement disorders;
- dystonia; and
- the compulsions of obsessive-compulsive disorder.

The second boundary is with normal childhood. Transient tics are common in school-age children and frequently resolve without ever crossing into a disorder, so the categories describe the impairing or persistent minority, not every child who blinks or clears the throat.

PITFALL

The commonest clinical error is to reach for a chronic-sounding label too early. A child seen a few weeks into a bout of blinking has, by definition, a provisional picture, and naming it Tourette's or a persistent disorder before the year has elapsed both overstates the prognosis to an anxious family and, because of the one-way hierarchy, is hard to walk back. The opposite error is to treat every fleeting tic as pathological, when brief tics are a common and usually self-limiting part of childhood. The clock, not the severity of a single clinic snapshot, decides the category.

IN INDIA

Routine Indian services classify under ICD rather than the manual these criteria are drawn from, and candidates should move comfortably between the two. The ICD scheme carries the same three-part structure under its own headings: a transient category for short-lived tics, a chronic motor or vocal category for the single-channel persistent form, and a combined category corresponding to Tourette's, so the logic of duration and modality transfers directly. The chief translation to remember is that the "provisional" label maps onto the older, and still widely used, term "transient tic disorder"; a child recorded as provisional under one system and transient under the other is the same child, filed by two manuals that agree on the substance.

GOOD TO REMEMBER

The category you assign changes the conversation you have. A provisional diagnosis is an occasion for measured reassurance, because most such tics remit; a persistent or Tourette's diagnosis reframes the problem as a longer-term condition whose burden usually comes less from the tics themselves than from the co-occurring attention and obsessional problems taken up elsewhere in this chapter. Assign the category by the rules, but let it, and not the alarming look of a bad spell of tics, set the tone of what you tell the family.

The one line to carry: duration sets provisional (under a year) against the persistent forms (over a year), modality sets single-channel persistent tic disorder against dual-channel Tourette's, and the hierarchy locks a higher diagnosis in place once it has been met.

Five	Under 1 year	Over 1 year	Both channels
TIC-DISORDER CATEGORIES	PROVISIONAL TIC DISORDER	PERSISTENT (CHRONIC) FORM	REQUIRED FOR TOURETTE'S

30 · Tourette syndrome diagnostic criteria and phenomenology

Tourette syndrome is the most recognisable and, in the public imagination, the most caricatured of the tic disorders, which is exactly why the exam tests whether a candidate can strip the caricature away and diagnose it on its actual rules. **Tourette's disorder** is a childhood-onset neurodevelopmental condition defined by the coexistence, at some point in the illness, of multiple motor tics and at least one vocal tic. A **tic** is a sudden, rapid, recurrent, non-rhythmic motor movement or vocalisation, and the whole diagnosis turns on recognising these movements for what they are and then applying four spare criteria that are almost entirely about pattern and time rather than about any single dramatic symptom. The marks here are not won by knowing that the condition exists; they are won by the discriminations - both tic types against one, the duration clock, the age ceiling - and by the phenomenology of the tic itself, which is what separates a tic disorder from every other movement disorder a child can present with.

This account owns the diagnostic criteria of Tourette's disorder and the phenomenology of tics: the criteria in full, the anatomy of simple and complex tics, the premonitory urge, the waxing-and-waning course, suppressibility and the factors that modify tics, the epidemiology across childhood, the trajectory into adult life and its suicide risk, and the standardised measurement of tic severity. The taxonomy of the tic disorders as a family - provisional, persistent and Tourette's - is set out in the classification account elsewhere in this chapter; the etiology and neurobiology, the pattern of comorbidity with attention-deficit/hyperactivity disorder and obsessive-compulsive disorder, the management of tics, and the formal differentiation of tics from stereotypies, chorea, dystonia and compulsions each belong to their own accounts here and are named only where the reasoning demands.

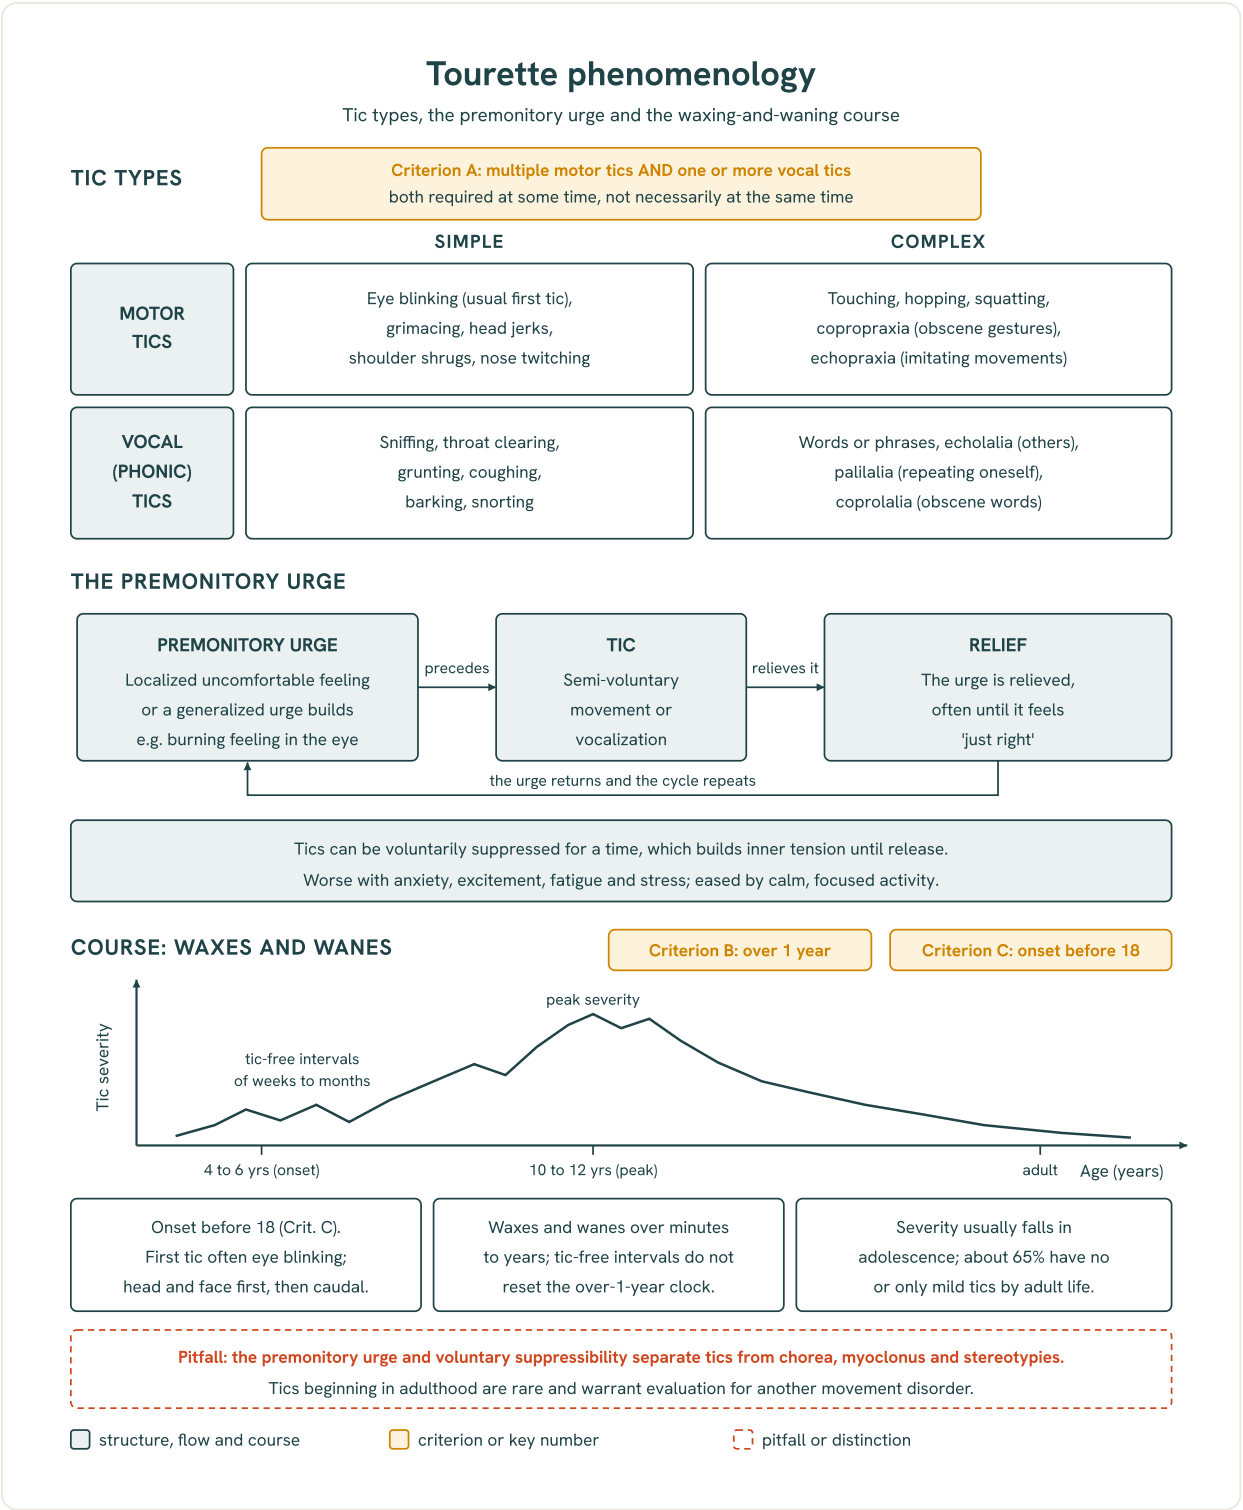

Fig 23.23. Tourette phenomenology: motor and vocal tics in simple and complex forms, the premonitory-urge-to-relief cycle, and the waxing-and-waning course from onset through peak severity to adult life.

30.1 Criterion A: both motor and vocal tics, and why that is the whole game

The single fact that makes a tic disorder Tourette's is the presence of both kinds of tic. Criterion A requires multiple motor tics and one or more vocal tics, and the crucial rider is that they must have been present at some time during the illness, though not necessarily concurrently. This is the discriminator that separates Tourette's from persistent (chronic) tic disorder, in which a child has motor tics only or vocal tics only but never both. A child may have had years of motor tics and only later develop a single throat-clearing or sniffing vocal tic; the moment both types

have been present, even if they never appeared in the same week, the diagnostic threshold for Tourette's is crossed. The corollary matters clinically: a boy currently showing only motor tics may still warrant the Tourette's label if a vocal tic featured earlier in his history, which is why the criterion is written around the whole course of the illness and not the cross-section in front of you. It is also why a careful longitudinal history, not just the present examination, is diagnostic.

RULE **Tourette's disorder is the tic disorder with both motor and vocal tics; the two types need never have coincided in time.** Persistent tic disorder carries one type only. The examiner is testing whether you read Criterion A across the lifetime of the illness rather than across the day of assessment, so a history of an earlier vocal tic in a currently motor-only child still satisfies it.

30.2 Criteria B, C and D: the duration clock, the age ceiling and the exclusions

The remaining three criteria are about time and attribution, and each is a discrete examinable rule. Criterion B is the duration requirement: the tics must have persisted for **more than one year** since the first tic appeared. The subtlety that catches candidates is that this clock is measured from the onset of the first tic and is *not* reset by tic-free intervals; the tics may wax and wane, and may even disappear for weeks, yet the year is counted from that first onset. Criterion C sets the age ceiling: onset of tics must be **before age 18**. A genuinely new tic disorder beginning in adult life is exceedingly rare and should prompt a search for another movement disorder or a secondary cause rather than a first diagnosis of Tourette's. Criterion D is the exclusion: the disturbance must be not attributable to the physiological effects of a substance or another medical condition, the classic offenders being a stimulant such as cocaine, and medical conditions such as Huntington's disease or a post-viral encephalitis. Together the four criteria form a pattern-and-time definition in which no single symptom is pathognomonic.

CRITERION	REQUIREMENT
A	Multiple motor tics and one or more vocal tics, at some time in the illness, not necessarily together
B	Tics have persisted more than one year from first onset, though they may wax and wane
C	Onset before age 18
D	Not attributable to a substance or another medical condition

The four diagnostic criteria of Tourette's disorder; A is the discriminator from persistent tic disorder, and B, C and D are the time-and-attribution rules that surround it.

MNEMONIC

Two types, one year, under eighteen, nothing else

Two types of tic, motor and vocal, at some time in the illness (A); persisting more than **one year** from first onset (B); onset **under eighteen** (C); and **nothing else** - not a substance and not another medical condition - accounting for it (D). Four spare rules, no single dramatic symptom, is the whole definition.

Carry into the exam: both multiple motor and one or more vocal tics at some time in the illness, persisting more than one year from first onset, with onset before age 18, and not due to a substance or medical condition.

30.3 The phenomenology of tics: simple, complex, and the first tic

Before the criteria can be applied, the movements have to be correctly identified as tics, and that is a phenomenological skill. Tics are conventionally sorted along two axes: motor against vocal, and simple against complex. **Simple tics** are brief and meaningless - an eye blink, a facial grimace, a head jerk or a shoulder shrug on the motor side; a sniff, a throat-clear, a grunt or a cough on the vocal side. **Complex tics** are longer, appear more purposeful and can look almost voluntary: touching, tapping, jumping or a coordinated sequence of movements on the motor side, and syllables, words or phrases on the vocal side. The complex vocal tics include the phenomena the condition is unfairly famous for - the involuntary utterance of obscenities, and the repetition of others' or one's own words - and it is worth stating plainly that these dramatic symptoms are uncommon and are in no way required for the diagnosis. Most patients never show them. The typical developmental sequence is characteristic: simple motor tics are the most common initial presentation, and eye blinking is the most common initial tic, with the tics tending to begin in the head and face and to progress caudally down the body as the child grows, complexity generally increasing with age.

	MOTOR	VOCAL (PHONIC)
Simple	Eye blink, grimace, head jerk, shoulder shrug	Sniff, throat-clear, grunt, cough
Complex	Touching, tapping, jumping, co-ordinated sequences	Syllables, words, phrases; ob-scene utterances and word repe-tition (uncommon)

Tics classified on the two axes; note that the socially notorious complex vocal tics sit in one cell only, are uncommon and are never a requirement for diagnosis.

TRAP **The involuntary utterance of obscenities is neither necessary nor common in Tourette's disorder.** Candidates, primed by the public image, treat it as the defining or even a required feature. It is a complex vocal tic seen in only a minority; a patient can have unmistakable Tourette's without ever producing it, and its absence never excludes the diagnosis.

30.4 The premonitory urge and the semi-voluntary quality of tics

The feature that most reliably tells a tic apart from another movement disorder is the sensation that precedes it. Older children and adults commonly describe a **premonitory urge** - a localised uncomfortable sensation or a more generalised inner tension that builds before the tic and is momentarily relieved by performing it. A patient may report a burning feeling in the eye that eases only on blinking, or a tension in the neck that resolves on jerking the head. The tic is often repeated until the sensation resolves and it feels just right, an experience that overlaps phenomenologically with the "just right" perceptions of obsessive-compulsive disorder and helps explain why the two conditions travel together so often. This urge-relief cycle is what gives tics

their peculiar *semi-voluntary* quality: the movement is experienced as neither wholly involuntary, like a chorea, nor wholly deliberate, but as a response to an internal pressure the patient can feel and partly control. Because young children may not yet be able to articulate the urge, its absence in a small child does not count against the diagnosis, but its presence in an older patient is strong confirmatory evidence that the movements are tics.

PITFALL

The semi-voluntary quality is regularly misread. Because a child can suppress the tics briefly and describes an urge behind them, teachers, parents and even clinicians conclude the movements are "a habit", "for attention" or "put on", and the child is disciplined rather than assessed. The urge and the partial control are intrinsic features of a neurological disorder, not evidence of volition or manipulation; reframing them for the family is often the first therapeutic act.

30.5 Course over time: waxing, waning and suppressibility

Tics are fundamentally fluctuating, and their fluctuation is a diagnostic feature rather than noise. Over the natural history the tics **wax and wane** in frequency, anatomical location, number, complexity and severity, changing over intervals as short as minutes and as long as years, and some individuals experience tic-free intervals of weeks to months. This waxing and waning is so characteristic that a movement disorder with a rigidly fixed, unvarying pattern should raise doubt about the diagnosis. Superimposed on this fluctuation is **suppressibility**: tics can be voluntarily held back for varying periods, usually at the cost of mounting inner tension that is then discharged in a flurry once the effort relaxes, which is why a child may appear tic-free in the clinic and then tic heavily on reaching the car. Tics are also state-dependent, increased by anxiety, excitement, fatigue and stress and reduced during calm, absorbing, focused activity. The examinable consequence bears repeating from the duration criterion: because the year is counted from the first tic, these tic-free stretches do *not* reset the one-year clock, and a child with three months of tics, two tic-free months and then further tics can still meet Criterion B.

- Fluctuation over minutes to years, with possible remissions of weeks to months, is expected and supports the diagnosis;
- brief voluntary suppression at the price of rising tension distinguishes tics from chorea and myoclonus, which cannot be held back;
- anxiety, excitement, fatigue and stress worsen tics, while calm focused engagement lessens them.

30.6 Epidemiology: how common, in whom, and when it starts

The epidemiology answers the two questions the exam asks around every childhood disorder - how rare is it really, and who gets it. Isolated tics are extremely common in childhood while Tourette's itself is uncommon, and holding those two facts together is the point. Transient tics affect a large minority of children - of the order of 5 to 20 per cent - and are usually self-limiting, whereas Tourette syndrome is far rarer, at around 0.7 per cent of children and adolescents. A meta-analysis of studies of children put the pooled prevalence at about 0.77 per cent, and a national survey estimate gave 3 per 1,000 clinically identified cases, with a school-age estimate of

3 to 9 per 1,000 children. The concordance of these independent figures around roughly three to eight per thousand is reassuring, and the takeaway is a rare disorder sitting under a very common symptom. The condition shows a consistent male predominance, with a male-to-female ratio of **2:1 to 4:1**. As for timing, the average age at onset is **4 to 6 years**, with tic severity typically greatest at 10 to 12 years before the usual adolescent decline, so a child most often presents in early school years and is at his worst around the transition to secondary school.

IN INDIA

Indian services classify under the ICD rather than the DSM, so the operative label in case files and referrals is the ICD tic-disorder entity, though the diagnostic logic - both tic types, more than a year, onset in childhood - is the same. In practice Tourette's is under-recognised here: mild tics are frequently dismissed as a "nervous habit" or as naughtiness by families and schools, the flamboyant complex vocal tics that would trigger referral are the exception rather than the rule, and children commonly reach a psychiatrist late, often only when a comorbid attention or obsessive-compulsive problem forces the issue. A low index of suspicion for the quiet, motor-tic-predominant child is the main corrective.

30.7 Prognosis into adulthood and the suicide risk

The natural history is, for most, genuinely encouraging, and that reassurance is part of good management. Tic severity most often declines through adolescence, and by early adulthood the majority have shed the bulk of their tics: 20 per cent or fewer continue to have significant functional impairment by the age of twenty, and about 65 per cent have no or only very mild tics by adult life. This favourable trajectory justifies a conservative, watchful stance in many children and a frank, hopeful conversation with families who arrive fearing a lifelong sentence. That optimism, however, must be balanced against a real and under-appreciated risk at the severe end of the spectrum. Among young people with a persistent tic disorder, about one in ten has suicidal thoughts or behaviours, and the disorder carries an increased risk of both suicide attempt (odds ratio 3.86) and death by suicide (odds ratio 4.39). This elevation persists after adjusting for psychiatric comorbidity, and the strongest predictors are persistence of tics beyond young adulthood and a previous attempt, so the very patients whose tics do not remit are the ones who most need active screening for suicidality rather than reassurance alone.

GOOD TO REMEMBER

Hold both messages at once. The default forecast you give a family of a newly diagnosed child is optimistic, because most tics fade by adult life. But the minority whose tics persist into and beyond adolescence, and anyone with a prior attempt, sit in a higher-risk group for suicide and deserve explicit, repeated safety screening. Do not let the good general prognosis lull you into skipping the risk assessment in the severe, persistent case.

30.8 Measuring severity: the standardised rating of tics

Diagnosis is clinical, but quantifying severity and tracking change calls for a structured instrument. The best-established is the **Yale Global Tic Severity Scale**, a clinician-rated instrument that scores motor and vocal tics separately across five dimensions - number,

frequency, intensity, complexity and interference - and adds a global impairment rating. Rating the two tic types on the same five axes captures the fact that a child may have many mild motor tics but a single highly disabling vocal one, or the reverse, and the separate impairment score records how much the tics actually cost the child in daily life, which need not track their raw frequency. Such standardised scales improve the reliability of diagnosis and give quantifiable baseline data - frequency and intensity - against which the response to any later intervention can be judged. They are tools for measurement and monitoring, not substitutes for the criteria: a high severity score confirms how bad the tics are, but the diagnosis itself still rests on the four-criterion pattern applied to the history. Comorbidity, chiefly with attention-deficit/hyperactivity disorder and obsessive-compulsive disorder, is usually what drives impairment beyond the tics themselves and is developed as a pattern in its own right elsewhere in this chapter; a severity rating is therefore read alongside, not instead of, an assessment of the comorbid load.

>1 year	2:1 to 4:1	4 to 6 yr	~65%
TIC DURATION FROM FIRST ONSET (CRITERION B)	MALE-TO-FEMALE RATIO	AVERAGE AGE AT ONSET	NO OR MINIMAL TICS BY ADULT LIFE

31 · Etiology and neurobiology of Tourette syndrome

Tourette syndrome is one of the few child psychiatric disorders whose story can be told at the level of a circuit, a neurotransmitter and a gene, and that is exactly why it is examined. A tic is a sudden, recurrent, non-rhythmic movement or vocalisation, and the question this topic answers is where in the nervous system such a fragment of movement is generated, why it is felt as almost-but-not-quite voluntary, and why it clusters so tightly in families. The honest summary a candidate must be able to give is that the disorder is understood as a developmental disturbance of the motor control loops that link the cortex to the deep grey matter, running on an abnormal dopaminergic tone, on a genetic substrate that is among the strongest in child psychiatry.

What makes the neurobiology worth teaching, rather than reciting, is that each strand of evidence carries a clinical corollary. The circuit model explains why tics are patterned and suppressible; the dopamine model explains why one class of drug calms tics and another provokes them; the genetic model explains why tics, obsessive-compulsive symptoms and inattention travel together in the same families. This account owns the etiology and neurobiology. The classification of the tic disorders, the diagnostic criteria and phenomenology, the comorbidity pattern, and the management of tics are each taught in their own accounts within this chapter and are named here only where the mechanism points to them.

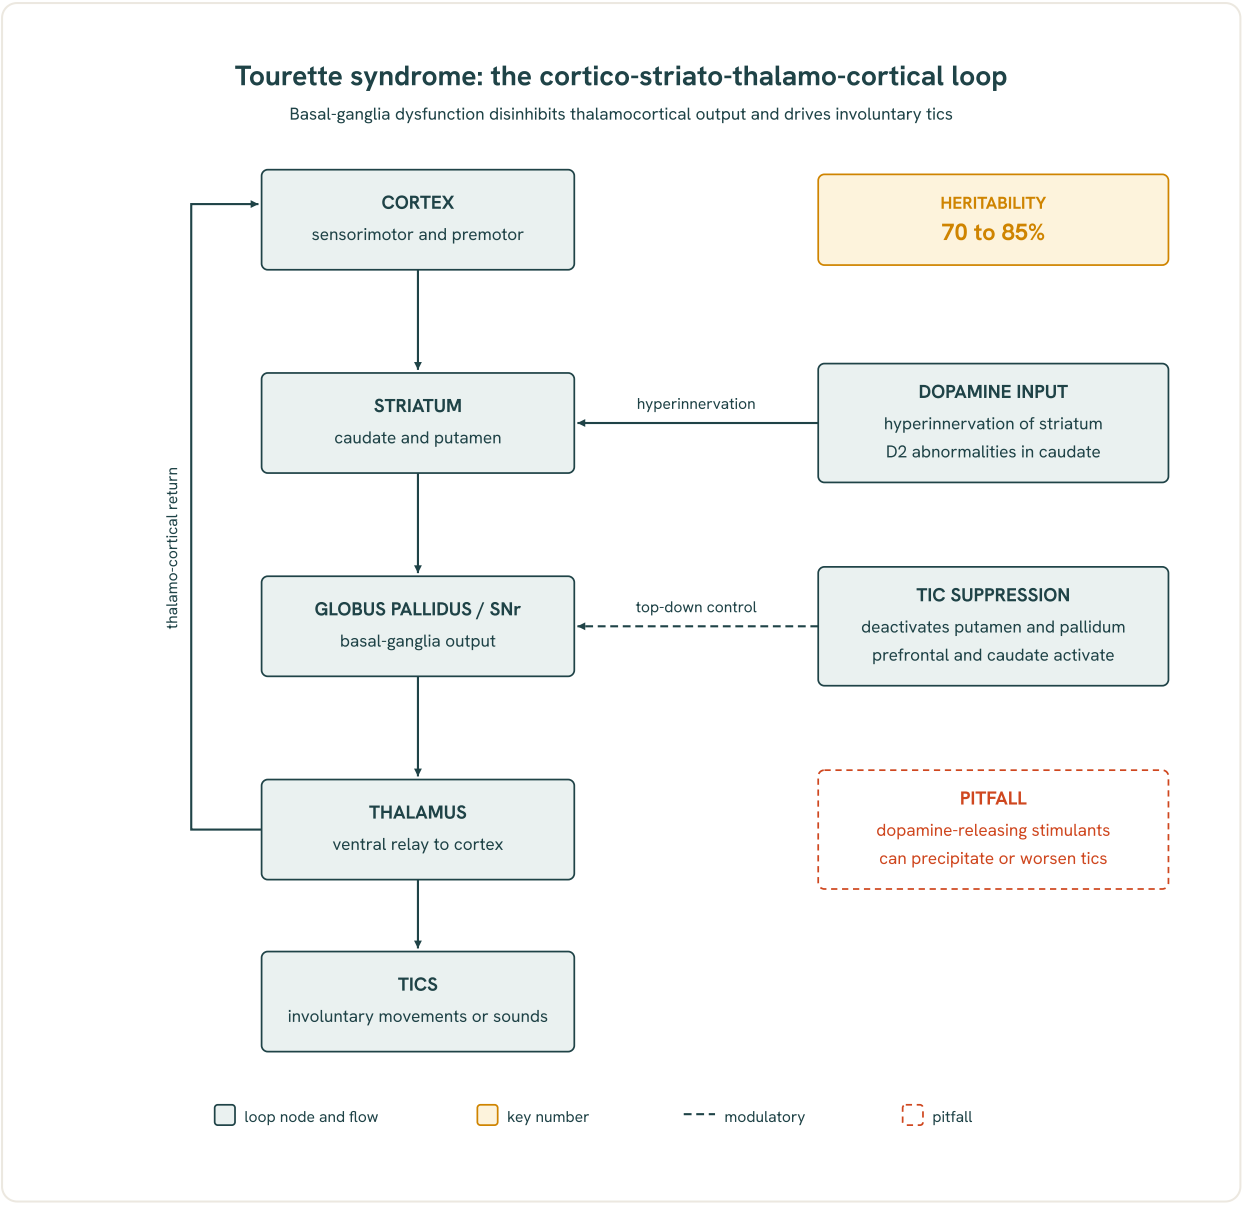

Fig 23.24. The cortico-striato-thalamo-cortical circuit in Tourette syndrome: dopaminergic hyperinnervation of the striatum dysregulates the basal-ganglia loop, disinhibiting thalamocortical output to produce tics.

31.1 A disorder of a motor circuit, not of a single brain region

The organising idea is that tics arise from dysfunction of the loops connecting cortex and basal ganglia, not from damage to one isolated structure. The prevailing model locates the disorder in the **cortico-striato-thalamo-cortical (CSTC) circuit**, the set of parallel loops through which the cortex projects to the striatum, the striatum to the pallidum and thalamus, and the thalamus back to the cortex, gating which motor programmes are released and which are held back. In Tourette syndrome this gating is faulty: fragments of movement that should be suppressed escape into action as tics. Volumetric and functional imaging support the model from several directions at once, implicating cortical thinning in the sensorimotor cortex, striatal structural anomalies and disruption of temporolimbic pathways. The last of these matters because it links the pure motor phenomenon to the affective and urge-laden quality that patients describe, and it is why the disorder sits with the neurodevelopmental conditions rather than with the movement disorders of later life.

MNEMONIC

Cortex - Striatum - Thalamus - Cortex

The name of the circuit is its own map, read in the direction the signal travels: the **C**ortex drives the **S**triatum, the striatum gates the pallidum and **T**halamus, and the thalamus closes the loop back to the **C**ortex. A tic is what happens when this loop fails to hold an unwanted motor programme in check, so every anatomical finding in this topic can be pinned to one station on the ring.

31.2 The basal ganglia as the hub of tic generation

Within that circuit, the weight of evidence falls on the basal ganglia. The **basal ganglia** - the striatum, comprising the caudate and putamen, together with the globus pallidus - are held to be central both to the generation of tics and to their suppression. Two findings anchor this. Structurally, a smaller **caudate** volume in childhood has been linked to worse tic severity in later life, which makes the caudate not merely a site of the lesion but a prognostic marker, one of the few in the disorder. Functionally, a greater capacity of the basal ganglia to suppress cortical activity is associated with lower tic severity, so the same structure that generates the intrusive movement also carries the machinery that damps it down. This is the anatomical reason the disorder is not static: the balance between generation and suppression can shift with maturation, which is part of why tics so often wax through childhood and settle in adolescence.

RULE **Tourette syndrome is a disorder of the cortico-striato-thalamo-cortical circuit with the basal ganglia at its hub, not a disorder of a damaged focal lesion.** The tic is a failure of the normal gating that decides which motor programmes reach the muscles. Every neurobiological finding worth memorising - the striatal anomalies, the caudate-severity link, the dopaminergic abnormality, even the response to medication - is a statement about this loop and its neurochemical tone, which is why the model unifies the imaging, the pharmacology and the natural history into one picture.

31.3 The neurology of voluntary tic suppression

The one feature that separates a tic from a chorea or a myoclonus is that a patient can hold it back, and the imaging of that effort is examinable. Tics are only partially involuntary: most patients can suppress them briefly, at the cost of a mounting inner tension that is relieved when the tic is finally released. When patients suppress tics voluntarily, imaging shows deactivation of the putamen and globus pallidus alongside activation of the prefrontal cortex and caudate. The reading is intuitive once the circuit is in mind: the prefrontal cortex and caudate exert top-down control that quietens the pallidal output driving the tic. This is not an academic detail. It is the neurobiological basis for the behavioural treatment of tics, in which patients are trained to deploy exactly this top-down control against the premonitory urge; that treatment is taught in the account of tic management in this chapter, and the mechanism here is what makes it rational rather than merely empirical.

31.4 The dopaminergic hypothesis

The best-supported neurochemical account is of an abnormal dopaminergic tone within these same striatal circuits. The **dopaminergic hypothesis** holds that tics arise from abnormal

dopamine neurotransmission, specifically an increased dopaminergic innervation, or hyperinnervation, of the striatum together with D2-receptor abnormalities in the caudate. Two independent lines of evidence converge on it:

- functional imaging with **SPECT** shows increased dopaminergic innervation of the striatum in affected individuals;
- studies of **monozygotic twins** discordant for severity show the D2-receptor abnormality to be greater in the more severely affected twin, tying the receptor finding directly to how ill the child is.

The twin observation is the more powerful of the two, because monozygotic co-twins share their entire genome: a difference between them in receptor binding that tracks their difference in severity points to something acting on the dopaminergic system beyond the inherited sequence, and it locates the abnormality in the caudate, the very structure the circuit model already implicated. Dopamine is the best-supported system but not the only one proposed; serotonergic, noradrenergic, glutamatergic and GABAergic contributions have all been suggested, though the evidence for them is weaker and none can be asserted here with the same confidence.

31.5 Pharmacological convergence: the drugs that prove the point

The strongest clinical argument for the dopamine model does not come from a scanner at all - it comes from watching what medicines do. The pharmacology converges on the hypothesis from both ends. **Dopamine-releasing drugs such as amphetamine precipitate or exacerbate tics, whereas dopamine D2-receptor-blocking neuroleptics suppress them**, and patients with the disorder release more dopamine in response to amphetamine than controls do. That double dissociation - worsen with a releaser, improve with a blocker - is difficult to explain on any model other than an overactive or oversensitive striatal dopamine system, and it is the reason the D2-blocking antipsychotics became the mainstay of pharmacological tic control, an application developed in the tic-management account of this chapter. The mechanism is owned here; the drugs, doses and titration belong there.

> **PITFALL**
>
> When a child with attention problems is started on a stimulant and tics appear or worsen, the reflex is to conclude the drug caused a new disorder. The mechanism argues otherwise: a dopamine-releasing agent unmasks or amplifies a tic diathesis that the CSTC and dopaminergic abnormality had already set up, rather than manufacturing Tourette syndrome from nothing. Reading the exacerbation as pharmacological proof of an underlying dopaminergic sensitivity, not as iatrogenic causation, keeps the clinician from both over-alarming the family and missing the co-occurring tic disorder; what to do about the stimulant itself is a decision for the comorbidity and management accounts.

31.6 A strongly heritable, polygenic disorder

Tourette syndrome and the tic disorders are among the most heritable conditions in child psychiatry, and the shape of that heritability is as examinable as its size. The **heritability** of tic disorders is estimated at roughly **70 to 85 per cent**, meaning that most of the variation in

whether and how severely tics appear is attributable to genetic factors. Two qualifications matter. First, there is no sex difference in the familial or heritable risk: although the disorder is expressed more often in boys, the underlying genetic liability is carried equally by both sexes, so a family history counts the same whether the affected relative is male or female. Second, the inheritance is **polygenic**: the liability is built from many genes of small effect rather than a single dominant locus, and the tic disorders most likely lie along a continuous developmental spectrum rather than forming a discrete category cut cleanly from the unaffected. This is why the search for a single Tourette gene failed and why the modern account is of accumulated common variation crossing a threshold.

31.7 A genetic architecture shared with OCD, ADHD and other neurodevelopmental disorders

The genetics do not stop at the tic - they reach across into the disorders that so reliably accompany it. Chronic tic disorders **share genetic variance** with obsessive-compulsive disorder, attention-deficit/hyperactivity disorder and other neurodevelopmental disorders including autism spectrum disorder. The common variants are shared in a graded fashion that correlates with severity, so the more heavily loaded a child is genetically, the broader and heavier the phenotype tends to be. This is the deep reason that tics rarely arrive alone: the same inherited liability that raises the risk of tics raises, in overlapping measure, the risk of obsessions, compulsions and inattention, which is why the clinically dominant problem is so often a comorbidity rather than the tic itself. The comorbidity pattern and the impairment it drives are taught in the dedicated account of Tourette comorbidities in this chapter; obsessive-compulsive disorder and attention-deficit/hyperactivity disorder as disorders in their own right belong elsewhere, the latter to the ADHD and specific learning/communication disorders notes. What this topic owns is the mechanism beneath the association: shared, graded, polygenic liability, not coincidence.

STRAND OF EVIDENCE	CORE FINDING	NATURE OF THE EVIDENCE	WHAT IT EXPLAINS
The circuit	CSTC dysfunction with sensorimotor cortical thinning and temporolimbic disruption	Volumetric and functional imaging	Why tics are patterned, gated movements with an urge quality
The hub	Striatum and pallidum central to tic generation and suppression; smaller childhood caudate tracks worse later severity	Structural and longitudinal imaging	The anatomical seat and a prognostic marker
The chemistry	Striatal dopaminergic hyperinnervation and caudate D2 abnormality	SPECT and monozygotic-twin studies	The neurochemical lesion and the drug response
The pharmacology	Releasers worsen tics, D2-blockers suppress them	Clinical and pharmacological convergence	Why antipsychotics calm tics and stimulants can provoke them
The genes	Strongly heritable and polygenic, with variance shared with OCD, ADHD and other neurodevelopmental disorders	Twin, family and molecular genetics	Familial clustering and the comorbidity pattern

The five convergent strands of the neurobiology of Tourette syndrome; each carries a clinical corollary, which is what makes the mechanism examinable rather than ornamental.

GOOD TO REMEMBER

Two things the neurobiology should change on Monday. Take a genuine family history in every child with tics, because the liability is strongly heritable and carried equally by both sexes, so an affected mother counts as much as an affected father. And when you counsel a family, frame the accompanying obsessive-compulsive or attentional symptoms not as separate misfortunes but as expressions of the same shared, graded genetic liability, which both normalises the pattern and prepares them for the comorbidity being the part that most needs treating.

31.8 Contested and environmental contributions

Genes set the liability, but they do not act in a vacuum, and the environmental side of the story is where confident teaching gives way to careful hedging. A polygenic liability expressed along a developmental spectrum implies that non-genetic factors help decide who crosses the threshold and how severely, and perinatal and other early influences have long been proposed as such modifiers; none, however, can be stated here as an established quantitative risk. The most examined and most contested environmental hypothesis is the post-infectious one, in which group A streptococcal infection is proposed to trigger tics through an autoimmune mechanism, described under the label PANDAS. That proposal is taught, with its evidence and its controversy, in the account of paediatric obsessive-compulsive disorder and PANDAS in this

chapter. It belongs in an etiology topic only as what it is: a proposed and genuinely contested infection-associated trigger, on limited evidence, and not an established cause of Tourette syndrome.

TRAP **Presenting PANDAS as a settled cause of Tourette syndrome is the classic examination error.** Candidates who have read about the autoimmune hypothesis reach for it as though a preceding sore throat closed the case, but the causal claim is contested and the evidence limited, and no examiner rewards stating it as established fact. The safe answer names PANDAS as a proposed, disputed infection-associated trigger and returns the weight of the etiology to where the evidence actually is: the heritable, polygenic disturbance of the cortico-striato-thalamo-cortical circuit and its dopaminergic tone.

IN INDIA

The neurobiology described here is built from imaging and molecular studies that a routine Indian clinic will never run: SPECT and volumetric MRI are research tools, not part of the diagnostic work-up, and the diagnosis of a tic disorder remains wholly clinical under the ICD framework used in Indian services. What the mechanism does change in practice is counselling. Because the disorder is strongly heritable and polygenic, a careful family history is the single most useful piece of the etiological assessment available at the bedside, and families - who often arrive fearing they caused the tics through parenting - can be told accurately that the liability is largely constitutional and inherited, not a product of upbringing or of any single event.

Carry into the exam: Tourette syndrome is a **70 to 85 per cent** heritable, polygenic neurodevelopmental disorder of the cortico-striato-thalamo-cortical circuit, with the basal ganglia at its hub and abnormal striatal dopaminergic tone, sharing its genetic liability with OCD and ADHD; dopamine releasers worsen tics and D2-blockers suppress them, and PANDAS is a contested trigger, never an established cause.

70-85% HERITABILITY OF TIC DISORDERS	**CSTC** THE IMPLICATED CORTICO-STRIATO-THALAMO-CORTICAL CIRCUIT	**Dopamine** STRIATAL HYPERINNERVATION AND CAUDATE D2 ABNORMALITY	**OCD, ADHD** DISORDERS SHARING TIC GENETIC VARIANCE

32 · Comorbidities (ADHD, OCD) in Tourette syndrome

Tourette's is almost never a disorder of tics alone. The great majority of people who reach a clinic with Tourette's carry at least one other psychiatric condition, and for most of them it is that accompanying condition, and not the movements, that drives them to seek help and that shapes the school years, the working life and the family's distress. Of all the conditions that keep Tourette's company, two stand out so consistently that they are best thought of as part of the syndrome's clinical identity rather than as chance neighbours. Attention-deficit/hyperactivity disorder and obsessive-compulsive disorder are the two **defining comorbidities** of Tourette's disorder, and their prominence holds in both clinical and community samples, which tells you that this is not simply a referral artefact of the most complicated patients reaching specialist care.

A candidate who pictures Tourette's as an isolated movement problem has the wrong mental model, and the exam is built to expose exactly that misconception.

This topic owns the comorbidity pattern in Tourette's: which conditions cluster with it, why that clustering matters more than the tics for outcome, and how that fact reorders the clinical priorities. It does not own, and must not re-teach, the disorders themselves. The full criteria, subtyping and treatment of **attention-deficit/hyperactivity disorder**, including its stimulant, non-stimulant and alpha-adrenergic agonist options, belong to the ADHD and specific learning/communication disorders notes; the criteria and management of **obsessive-compulsive disorder** belong to the Anxiety, OCD and trauma-related disorders notes. What is taught here is the overlap and its consequences, which is where the marks in this area actually sit.

32.1 Comorbidity is the rule, not the exception

The isolated tic patient is the unusual one. The single most important reframing in this topic is that a person presenting with Tourette's and nothing else is the minority case. Co-occurring psychiatric disorder is so common that a clinician who fails to look for it will miss the larger part of the patient's difficulty. That the same two conditions, ADHD and OCD, dominate the comorbidity profile in community samples as well as in clinics matters for a precise reason: if the association held only in specialist series it could be dismissed as referral bias, the sickest and most tangled patients being the ones who reach tertiary care. Because it holds in the community too, the link is a property of the syndrome itself and not of who happens to be referred. This is why the modern account of Tourette's treats it as a neurodevelopmental condition whose psychiatric comorbidity is intrinsic, and why screening for that comorbidity is a mandatory part of every assessment rather than an optional extra.

32.2 ADHD: the earliest and often the most disabling companion

The inattention and impulsivity usually arrive before the tics and outlast the clinic's attention to them. Of the two defining comorbidities, ADHD is typically the one that declares itself first, its inattention, restlessness and impulsivity commonly evident in the years before the tics emerge and are recognised. For the child, this ordering has a cruel consequence: the academic and social damage of untreated attention and impulse difficulties is often well established by the time anyone notices the tics and attaches the Tourette label. The impairment of comorbid ADHD in this population lands where impairment always does with ADHD - on learning, on the ability to hold a place in the classroom, on peer relationships and on family life - and it frequently exceeds anything the tics themselves are doing. The natural clinical error is to let the visible, dramatic movements monopolise the consultation while the quieter but more corrosive attentional problem goes unaddressed. The specific pharmacology of ADHD, and the long-standing question of using stimulants in a child who also tics, are matters for the ADHD and specific learning/communication disorders notes; the point that belongs here is simply that ADHD is usually present, usually early, and usually the heavier burden.

32.3 OCD: the obsessive-compulsive phenomena that shade into the tics

The obsessive-compulsive side of Tourette's has a texture of its own. Obsessive-compulsive disorder is the second defining comorbidity, and in the Tourette context it tends to wear a characteristic face. What many patients describe is a **tic-related OCD**: compulsions driven less by a fear of catastrophe and more by an intolerable sense that something is not yet complete or symmetrical, an urge to touch, tap, order, count or repeat until an internal feeling of "just right" is reached. This blurs, at its edges, into the tics themselves, because the more complex tics and the simpler compulsions can be hard to tell apart, both being preceded by an uncomfortable inner urge that the act discharges. That overlap is diagnostically important and is developed where the phenomenology of tics is taught in this chapter; here the essential message is that OCD is a defining companion of Tourette's and that its presentation in this group leans towards the symmetry-and-completion phenotype rather than the contamination-and-checking picture. The criteria, the full symptom dimensions and the treatment of OCD are the province of the Anxiety, OCD and trauma-related disorders notes, and nothing about them is re-taught here.

32.4 The overlap seen from the OCD side: tics within OCD and the triad

Look at the same relationship from the obsessive-compulsive end and it points straight back to tics. The comorbidity is genuinely bidirectional, and the exam likes to test it from the OCD direction because that is where a clean, quotable figure exists. Among people whose primary diagnosis is OCD, **up to 30%** carry a lifetime tic disorder, and this comorbid tic disorder is most common in men whose OCD began in **childhood-onset OCD**. In children in particular the three conditions cluster together often enough to be named as a unit: a **triad of OCD, tic disorder and ADHD** that can be seen presenting together. Recognising the triad matters clinically because encountering any one of its members should prompt a deliberate search for the other two; the child referred for compulsions may have unrecognised tics and untreated inattention sitting behind them, and the whole picture, not the presenting fragment, is what has to be managed. This is the overlap that the older literature gathered under the loose heading of a Tourette-associated or "Tourette-plus" pattern, and it is the reason the tic disorders and the obsessive-compulsive disorders are read together rather than in separate silos.

32.5 The Tourette-plus phenotype and where the impairment actually sits

Add the comorbidities to the tics and you have described most real patients. Pure Tourette's, tics and nothing more, is the textbook simplification; the common clinical reality is the **Tourette-plus** picture, in which the tics are accompanied by ADHD, or by OCD, or by both, frequently alongside further difficulties such as co-occurring mood and anxiety disturbance. The reason this composite label earns its keep is not tidiness but prognosis. In these patients the condition that most damages daily functioning is usually not the tics but the accompanying disorder: the inattention that sinks the school report, the compulsions that consume hours of the day, the anxiety or low mood that closes the world down. The tics may be what an observer notices first and what the family finds most socially exposing, yet when you total up the lost function, the comorbidity is generally the larger contributor. Holding that ranking in mind is

what separates a clinician who treats the noisiest symptom from one who treats the most disabling one.

RULE **In Tourette's, the comorbidity usually decides how disabled the patient is, not the tics.** Tic frequency and tic severity are a poor guide to overall functioning, because the co-occurring ADHD, OCD, anxiety or mood disorder typically carries more of the impairment. Assess the whole comorbidity load before you judge how ill the patient is, and never let the visibility of the movements stand in for a measure of the disability.

32.6 The clinical logic: treat the comorbidity, often before the tics

The order of treatment follows the order of impairment. If the comorbid condition is usually the greater source of disability, then the sequencing of management follows almost automatically: in most Tourette-plus patients the comorbidity is identified and treated first, and in a good number the tics need no direct drug treatment at all once the ADHD or the OCD is under control and the associated distress has eased. This is not a rule that the tics are ignored, but a rule of priorities - you address what is doing the most harm before you turn to what is most conspicuous. It also reframes the whole assessment: a proper Tourette's evaluation is as much an inventory of the accompanying conditions and their relative impact as it is a characterisation of the tics. The behavioural and pharmacological treatment of the tics themselves is developed elsewhere in this chapter; what this topic establishes is the reasoning that so often places that tic treatment second in the queue.

DEFINING COMORBIDITY	HOW IT RELATES TO THE TOURETTE PICTURE	WHERE ITS IMPAIRMENT PRINCIPALLY LANDS
ADHD	Usually the earliest problem, often evident before the tics are recognised; the commonest companion of Tourette's	Learning and academic attainment, classroom conduct, peer relationships and family strain
OCD	Frequently a symmetry-and-completion, tic-related pattern that blurs at its edge into the more complex tics	Time lost to compulsions, internal distress from the "not just right" urge, and rigidity of routine
Mood and anxiety disorders	Common further companions in the Tourette-plus picture rather than defining ones; named, not the focus here	Withdrawal, avoidance and lowered mood that constrict daily life beyond what the tics do

The comorbidity pattern of Tourette's read as a whole: the two defining companions and the further conditions that complete the Tourette-plus picture, set against the domain each one chiefly disables. The tics are frequently the least of it.

- ADHD and OCD are the two defining comorbidities, present in clinical and community samples alike;
- the overlap is bidirectional - a substantial share of OCD patients carry a lifetime tic disorder;
- in children the three may cluster as an OCD, tic disorder and ADHD triad;
- the comorbidity usually causes more functional impairment than the tics;

- so assessment inventories the comorbid load, and treatment commonly addresses it first.

32.7 The wider company Tourette's keeps

Beyond the defining pair, a broader psychiatric load is the norm. Naming ADHD and OCD as the defining comorbidities does not mean they are the only ones. Mood and anxiety disorders co-occur with Tourette's frequently enough to belong in every assessment, the anxiety spectrum running from separation anxiety in the younger child to generalised anxiety, both of which are taught in their own right elsewhere in this chapter and are only named here as members of the comorbid picture. The practical implication is cumulative: because several conditions may stack on top of the tics, the disability a Tourette's patient carries is often the sum of a number of partly independent problems, each needing its own recognition. A clinician who screens only for the two headline comorbidities and stops there will still under-count the burden. The discipline the topic asks for is a systematic sweep across attention, obsessive-compulsive phenomena, mood and anxiety in every patient who presents with tics, rather than a search confined to whichever symptom happens to be loudest on the day.

In Tourette's, screen every patient for ADHD and OCD, and remember the comorbid condition usually disables more than the tics do.

TRAP **Assuming that tic severity tracks overall impairment.** The classic examination error is to grade a Tourette's patient's illness by how frequent or forceful the tics are. Candidates make it because the tics are the visible, nameable feature and feel like the measure of the disorder. In fact the co-occurring ADHD, OCD, anxiety or mood disorder is usually the heavier burden, so a patient with modest tics and severe untreated ADHD may be far more disabled than one with florid tics and nothing else.

PITFALL

The commonest management failure is to pour the consultation into suppressing the tics while the comorbid ADHD or OCD goes untreated. The movements are what the family points to and what draws the eye, so effort and medication get spent on them, and meanwhile the child's schooling collapses under unmanaged inattention or their waking hours are eaten by compulsions. The corrective is to rank the sources of impairment before reaching for a tic drug, and to treat the condition that is doing the most harm first.

GOOD TO REMEMBER

What changes on Monday is the shape of the assessment. Every patient who presents with tics is screened deliberately for attention and impulse problems and for obsessive-compulsive phenomena, and the relative impairment of each is weighed before any treatment plan is drawn. If the comorbidity is the greater burden, it is named as the priority in the plan and addressed first; the tics can very often wait, and sometimes need no direct drug treatment once the comorbidity is controlled.

IN INDIA

Two realities of Indian practice sharpen this topic. First, tics are frequently dismissed by families and even by non-specialists as mere habits or naughtiness, so the child often reaches services not for the movements but for the school failure of comorbid ADHD or the puzzling rituals of comorbid OCD; the comorbidity is the presenting complaint far more often than the tics are. Second, specialist tic services are scarce and unevenly distributed, which makes the impairment-first logic doubly useful: a general psychiatrist or paediatrician who cannot offer sophisticated tic-directed therapy can still transform a child's life by recognising and treating the accompanying ADHD or OCD, which is usually where the real disability sits anyway.

33 · Management of tics (habit reversal, CBIT, pharmacotherapy)

Most people with tics never need a drug, and knowing when not to prescribe is the larger part of the skill. Tics wax and wane, peak in the early school years and often settle through adolescence, so the management question is rarely "which medication" and much more often "does this child need any active treatment at all, and if so, what is the least intervention that restores function". The marks go to the candidate who holds that restraint and then doses each agent to its tic indication rather than to a number learned for a different one.

This section owns the treatment of tics in full: the decision to treat, the behavioural first line of habit reversal and its parent programme, the stepped sequence of drugs, and every tic-indication dose with its monitoring. The phenomenology of tics, the diagnostic criteria of Tourette syndrome and the comorbidity pattern of attention-deficit/hyperactivity disorder and obsessive-compulsive disorder are developed elsewhere in this chapter and named here only where a treatment decision turns on them.

Fig 23.25. Tic management ladder: habit reversal training within CBIT first for mild to moderate tics, then an alpha-2 agonist (clonidine or guanfacine), then an antipsychotic (aripiprazole or risperidone). Aripiprazole is the tic-licensed choice at the antipsychotic step, and its dose is given by weight band rather than as a single range because the upper end of that range is licensed only for patients of 50 kg or more. Clonidine, guanfacine and risperidone are used off-label and have no licensed tic dose, so no dose is printed for them: what is shown instead is the labelled absence itself, and for risperidone a named trial's mean, labelled as a trial mean and not a regimen. Haloperidol and pimozide are also tic-licensed but are held in reserve on tolerability and cardiac grounds.

33.1 Deciding to treat, and the order of treatment

Treatment is aimed at impairment, not at the tic count. A child whose tics are noticed but not distressing, not painful and not disrupting learning or relationships usually needs psychoeducation, reassurance and school liaison, and nothing more. Active treatment is reserved for tics that hurt, that draw bullying, that interrupt schooling or that the young person themselves wants reduced. When treatment is warranted it follows a deliberate sequence rather

than a menu: educational and behavioural treatment first, then an **alpha-2 agonist** if a drug is needed, then an antipsychotic, and only then the older or experimental agents. An alpha-2 agonist is generally tried before an antipsychotic because the adverse-effect cost of an antipsychotic can outweigh its benefit in a fluctuating, often self-limiting condition.

Comorbidity reorders the whole plan. Where attention-deficit/hyperactivity disorder or obsessive-compulsive disorder coexists, the comorbid disorder is frequently the greater source of impairment and is usually treated first, because controlling it can make the tics feel manageable without a tic-specific drug. This is also why the alpha-2 agonists are attractive: they address tics and the comorbid hyperactivity together.

Stimulants are not contraindicated in tic disorders, and believing that they are withholds the treatment most likely to help. Current labelling for methylphenidate and for amphetamine places tics and Tourette's under warnings and precautions only, never under contraindications, which list nothing but hypersensitivity and recent or concurrent monoamine oxidase inhibitor use; what the label actually requires is that the family history be taken and the patient clinically evaluated for tics before starting, that treatment be monitored regularly for the emergence or worsening of tics, and that it be discontinued if that becomes clinically appropriate. The group-level evidence is flat: a meta-analysis of 22 randomised placebo-controlled trials in 2,385 children found new-onset or worsening tics in 5.7% on psychostimulant against 6.5% on placebo, a risk ratio of 0.99 (95% CI 0.78 to 1.27), with no moderating effect of stimulant type, dose, duration of treatment, recorder or age. Because tics wax and wane on their own, a worsening that follows a stimulant start is much more likely coincidence than cause, and rechallenge may be considered. Where a child has both tics and ADHD, methylphenidate, clonidine, clonidine with methylphenidate, and guanfacine are each probably more likely than placebo to reduce tic severity as well as ADHD symptoms, and the clinician should ensure that functionally impairing ADHD is treated.

RULE **Behavioural treatment leads, an alpha-2 agonist comes before an antipsychotic, and most tics need no drug at all.** Escalation is stepwise and impairment-driven, and comorbidity is usually treated first. Opening with an antipsychotic skips the two steps before it and inverts the safety logic of the ladder.

Carry this into the exam: treat the impairment not the tic, lead with education and habit reversal, use an alpha-2 agonist before an antipsychotic, and treat the comorbidity first, stimulant and all.

33.2 Habit reversal training and CBIT: the behavioural first line

The first-line active treatment is behavioural, and it is more than distraction. **Habit reversal training** is the core of Comprehensive Behavioural Intervention for Tics, the first-line treatment when a child with mild to moderate tics needs active intervention. Its power rests on a physiological fact: most tics are preceded by a **premonitory urge**, an uncomfortable building

sensation that the tic momentarily discharges. Because the urge precedes the movement, the movement can be intercepted. The programme layers components onto that:

- awareness training, teaching the young person to detect the urge and the earliest signs of the tic;
- **competing response** training, in which they perform a voluntary movement incompatible with the tic and hold it until the urge subsides;
- relaxation training, contingency management and social support, with parents coached to prompt and reward home practice;
- relapse prevention, so gains survive the next natural worsening of the tics.

The mechanism is a controlled extinction of the urge-to-tic loop: repeatedly meeting the premonitory urge with a competing response rather than the tic weakens the urge over time, so the behaviour is not merely suppressed by willpower but progressively unlearned. This is a tic-specific technique and should not be confused with the exposure and response prevention used for paediatric obsessive-compulsive disorder; the competing response is a motor substitution against an urge, not a graded exposure to a feared thought. Behavioural treatment is well supported, with effect sizes broadly comparable to antipsychotic medication for tic reduction, which is precisely why it, and not a drug, sits at the head of the active-treatment ladder. Its practical limits are access and effort: it needs a trained therapist, a child old enough to report the urge and monitor themselves, and sustained home practice.

MNEMONIC

Aware, Compete, Relax, Reward, Sustain

The working parts in order: **aware**ness of the premonitory urge, a **compet**ing response against it, **relax**ation to lower baseline arousal, **reward** for practice through contingency management and social support, and relapse prevention to **sustain** the gains.

33.3 The alpha-2 agonists: clonidine and guanfacine

When a drug is needed, the alpha-2 agonists are the first rung and the safest place to start. The thing most sources leave out: in none of the labelling this chapter has read, that of the United Kingdom, the European Union, Australia and the United States, is either agent licensed for tics, so neither has a licensed tic dose. **Clonidine** is used off-label; every clonidine product this chapter has checked is licensed for something else: hypertension, ADHD in its extended-release form, or, in United Kingdom labelling, migraine prophylaxis and menopausal flushing. Current labelling supplies no starting dose, no frequency, no titration interval and no maximum for the tic indication, precisely because no clonidine product carries a tic indication, and no ceiling licensed for another indication may be imported as the tic ceiling. That absence is the teaching, not a gap in it: the weight-based figure circulating in the textbooks is an order-of-magnitude target, not a regimen, so it cannot be prescribed from and has no business on a dosing page. The American Academy of Neurology's 2019 practice guideline recommends clonidine for tics where the benefits outweigh the risks, and directs counselling about sedation, monitoring of heart rate

and blood pressure, and gradual tapering, but it publishes no dose at all. The United Kingdom position is blunter still: both UK oral clonidine labels state that there is insufficient evidence for its use in children and adolescents under 18 and that clonidine is therefore not recommended in them, and both record that its efficacy in Tourette syndrome has not been demonstrated. Its adverse effects are the reason to go slowly: sedation, postural hypotension and low mood. On the evidence, people with tics given clonidine are probably more likely than placebo to have reduced tic severity, and the effect is larger where ADHD is comorbid.

Guanfacine is the more selective alpha-2A agonist and tends to sedate and lower blood pressure less. It too is used off-label for tics and has no licensed tic dose; its licensed indications are hypertension and ADHD, and people with tics given guanfacine are only possibly more likely than placebo to have reduced tic severity, a weaker grade of evidence than clonidine's, with the effect again larger where ADHD is comorbid. The milligram figures most trainees recite for guanfacine are the ADHD figures, so any milligram number offered for guanfacine in tics must be traceable to a named tic trial and labelled as that trial's dose, never lifted from a monograph range. There is a tic-specific efficacy anchor: in an 8-week double-blind randomised trial of children who had both a tic disorder and ADHD, guanfacine reduced tic severity by **31%** against no change on placebo.

The monitoring for this class is mandatory, and it is not only about sedation. For either alpha-2 agonist in tics, the physician must counsel the patient about common adverse effects including sedation, must monitor heart rate and blood pressure, and must taper the drug gradually on discontinuation to avoid rebound hypertension; the class should be prescribed when the benefits of treatment outweigh the risks. Those are level A requirements, not counsels of perfection. Guanfacine also carries a cardiac requirement: a physician prescribing extended-release guanfacine must monitor the QTc interval in a patient with a history of cardiac conditions, in a patient taking other QT-prolonging agents, and in a patient with a family history of long QT syndrome, also a level A requirement. The cardiac warning does not begin at the classical agents; it begins on the second rung.

The alpha-2 agonists are also used in ADHD, where they do have a licence and a licensed dose, and for that alpha-2 dose the reader should cross-refer the ADHD and specific learning/communication disorders notes. Those numbers belong to that indication, and there is no tic-indication counterpart to which they could be transferred.

TRAP **Reciting the ADHD-indication alpha-2 dose as if it were the tic dose.** The same two drugs, clonidine and guanfacine, are prescribed for ADHD and for tics, and a candidate who has memorised one milligram figure will offer it for the other indication. This trap is sprung more often than any other on this topic, and printed sources spring it too: the guanfacine range in general circulation fuses the hypertension dose of the immediate-release form with the ADHD dose of the extended-release form, and neither has anything to do with tics. Neither agent has a tic-indication dose at all, which is the answer the examiner is listening for. Naming the drug is not enough; the examiner wants the dose scoped to the indication in front of you, and wants you to say so when no such dose exists.

PITFALL

Stopping clonidine suddenly. Because it is sedating and sometimes only modestly effective, a frustrated family may simply discontinue it, and an abrupt stop of a central alpha-2 agonist risks rebound hypertension. Whenever clonidine or guanfacine is prescribed for tics, the taper and the instruction never to stop it suddenly are part of the prescription, not an afterthought.

33.4 The antipsychotics for tics: aripiprazole and risperidone

When tics are severe or the alpha-2 step has failed, a dopamine blocker is the most reliable suppressor, at a price. Tics respond to dopamine D2 blockade, which is why antipsychotics work and why their metabolic and motor costs are the reason they are not first. **Aripiprazole** is the usual modern choice and the only one of the two antipsychotics taught at this step that carries a tic licence: it is FDA-approved for Tourette's disorder in children and adolescents aged 6 to 18, with a recommended range of **5 to 20 mg/day**. That range is a whole-population envelope, not a prescribable instruction, and it must never be quoted or printed without the weight bands beside it, because its upper end is licensed only for the heavier band. Three agents here hold a United States tic licence: aripiprazole, haloperidol and pimozide. A licence is not a place in the sequence: both classical agents are licensed and sit low anyway, on tolerability and cardiac grounds, and pimozide's licence is itself written only for patients who have failed to respond satisfactorily to standard treatment. What separates aripiprazole is not freedom from cost, but that its cost is not the sedation, extrapyramidal burden and QTc surveillance the classical agents bring.

The bands are these, of a tablet taken once a day: the labelled formulation here is the oral tablet, administered once daily without regard to meals. A patient weighing less than 50 kg is started at 2 mg/day, with a target of 5 mg/day after 2 days, which may be increased to 10 mg/day if optimal tic control is not achieved; 10 mg/day is that patient's maximum. A patient weighing 50 kg or more is started at 2 mg/day for 2 days, then 5 mg/day for 5 days, with a target of 10 mg/day on the eighth day; only where optimal tic control is not achieved may the dose rise in increments of 5 mg/day to a maximum of 20 mg/day. In either band, dosage adjustments are made gradually, at intervals of no less than one week. The one-week rule and the two-day step are not in conflict: the staged schedule above is the label's own initial titration, and the one-week interval governs the discretionary adjustments made after it. The staged steps are the schedule; everything after them is an adjustment, and adjustments wait a week. Two distinctions carry the marks and the safety. The first is the band boundary itself: less than 50 kg against 50 kg or more, so that a child of exactly 50 kg is not left between two regimens. The second is target against ceiling: for the heavier band 10 mg/day is the recommended dose and 20 mg/day is a ceiling for those who do not respond, not a destination. A bare "5 to 20 mg/day", carried into a viva or printed on a plate without its bands, licenses double the labelled maximum in a patient under 50 kg. The trial evidence supports both the drug and the low starting doses: in a placebo-controlled trial of children and adolescents with Tourette's, both a low-dose and a high-dose aripiprazole arm reduced tics, with roughly 69% much or very much improved on low dose and 74% on high dose against 38% on placebo, at a modest average weight gain.

Risperidone is also effective for tics, but off-label and with no licensed tic dose. Its licensed indications are schizophrenia in adolescents from 13 to 17 and in adults, acute manic or mixed episodes of bipolar I disorder from 10 to 17 and in adults, and irritability associated with autistic disorder from 5 to 16; tics are nowhere among them, and each of those indications carries its own separate dose. So the only risperidone figure that may honestly be quoted for tics is a trial's descriptive number, answering a question about the evidence, not about how to prescribe: in the landmark tic trial the mean effective dose settled at about **2.5 mg/day** over 8 weeks and cut the **Yale Global Tic Severity Scale** Total Tic score by about 32%, with a mean weight gain of 2.8 kg that captures the class liability in a single number. That Total Tic score is the standard primary endpoint against which tic treatments are judged. Risperidone is probably more likely than placebo to reduce tic severity, at a higher risk of drug-induced movement disorders, weight gain and somnolence. Say "the trial mean was about 2.5 mg/day, a trial mean rather than a regimen" and you have answered honestly. The figure carries no starting dose, no titration increment, no dosing interval and no maximum, which is what separates a descriptive number from a prescribable one. Offer instead the low paediatric range that circulates for risperidone and you have quoted a general envelope belonging to the autism and mania indications, sitting below the anchoring tic trial's own mean effective dose, which is the tell that it was never a tic dose.

GOOD TO REMEMBER

With any antipsychotic used for tics, the dosing method is start low, titrate slowly and monitor deliberately, because the tic dose is often lower than the antipsychotic dose you would reach for psychosis and because a growing child pays the metabolic bill. Track weight and metabolic parameters from the outset; the full adverse-effect and monitoring profile of these agents is developed with the antipsychotics themselves, but the weighing starts on the first prescription.

33.5 The classical agents: haloperidol and pimozide, and the ECG

The older high-potency agents still suppress tics powerfully, but tolerability and cardiac safety have moved them down the ladder. Haloperidol is FDA-approved for the control of tics and vocal utterances of Tourette's disorder in children and adults, and its labelled paediatric regimen is narrow: it is written for children between 3 and 12 years of age, in the weight range 15 to 40 kg, and is not intended for a child under 3. Within that band, therapy begins at the lowest dose possible, 0.5 mg/day, and is raised by increments of 0.5 mg at 5 to 7 day intervals until the desired therapeutic effect is obtained, with the total daily dose divided and given twice or three times a day, working toward a target of 0.05 to 0.075 mg/kg per day for Tourette's and the other nonpsychotic behaviour disorders, a deliberately lower target than the 0.05 to 0.15 mg/kg per day used for psychotic disorders. The maximum is an honest absence rather than a number: no maximum effective dosage has been established, and there is little evidence that improvement is further enhanced beyond 6 mg/day. That is a ceiling on expected benefit, not a licence to climb toward it. Haloperidol is often poorly tolerated, with sedation and extrapyramidal effects.

Pimozide, a classical D2 antagonist reserved for patients who have failed standard treatment, is used to suppress motor and phonic tics at a usual range kept under **10 mg/day**. Reliable dose-

response data for its effect on tics below the age of twelve are not available, which is itself worth saying aloud before prescribing it to a younger child. In children it is started at 0.05 mg/kg per day, preferably taken once at bedtime, and may be increased every third day to a maximum of 0.2 mg/kg per day, not to exceed 10 mg/day.

Those dose mechanics are governed by a pharmacogenomic gate, the part candidates omit. At doses above 0.05 mg/kg per day, CYP2D6 genotyping should be performed; in a poor CYP2D6 metaboliser the dose should not exceed 0.05 mg/kg per day and should not be increased earlier than 14 days. Roughly 5 to 10% of the population are poor CYP2D6 metabolisers, and they reach pimozide concentrations similar to those seen with a strong CYP2D6 inhibitor such as paroxetine; because their half-life is prolonged, steady state takes about 2 weeks to arrive, so alternative dosing strategies are recommended for them. The standard titration, moving every third day, therefore outruns the drug in exactly the patients who accumulate it, which is why the interval stretches to a fortnight rather than the dose merely being capped.

The safety-critical point is cardiac. ECG monitoring is essential for both haloperidol and pimozide when they are used for tics. Pimozide in particular causes dose-dependent QTc prolongation with a real risk of ventricular arrhythmia and sudden death, so before and during treatment one must obtain a baseline ECG and serum potassium and monitor periodically, especially during titration. Sudden unexpected deaths have occurred at high doses and patients must not exceed the prescribed dose. The interactions must be filed under the right enzyme and at the right severity. Pimozide is metabolised mainly by CYP3A4 and, to a lesser extent, by CYP1A2 and CYP2D6. Inhibitors of CYP3A4, including macrolides, azole antifungals and grapefruit juice, raise pimozide levels and arrhythmia risk. Strong CYP2D6 inhibitors are a different matter: paroxetine and the other strong CYP2D6 inhibitors are contraindicated with pimozide outright, pimozide 2 mg given with paroxetine 60 mg having raised pimozide AUC by 151% and Cmax by 62%. Filing paroxetine under CYP3A4 as a mere caution gets both the enzyme and the severity wrong, and the pairing is a live one: a child with tics and comorbid obsessive-compulsive disorder is exactly the patient in whom an SSRI and pimozide might otherwise meet.

33.6 Measuring response and assembling the plan

A defensible answer sets out the whole staged plan and says how response is judged. Response is tracked against a validated tic-severity endpoint rather than a clinician's impression, which is what lets a service tell genuine improvement from the natural waning of the tics. Put together: assessment and psychoeducation, comorbidity treated, habit reversal as the active first line, an alpha-2 agonist when a drug is needed, an antipsychotic for severe or refractory tics, and the classical high-potency agents held in reserve under cardiac monitoring. The figure and the table below set the agents against their line and their tic-indication dose. Read both with the same question in hand: for this agent, is there a licensed tic dose at all, and if not, what exactly am I quoting?

AGENT	PLACE IN THE LADDER	TICS: THE LICENSED DOSE, OR WHAT THE FIGURE ACTUALLY IS	CHIEF CAVEAT
Clonidine	Alpha-2 agonist; first drug step	Off-label; no licensed tic dose. No licensed start, interval or maximum for tics; UK labelling does not recommend clonidine under 18 at all	Sedation, postural hypotension; monitor heart rate and blood pressure; taper, never stop abruptly
Guanfacine	Alpha-2A agonist; first drug step	Off-label; no licensed tic dose and no tic-scoped milligram figure	Less sedating than clonidine, but extended release requires QTc monitoring where there is cardiac history, other QT-prolonging drugs or a family history of long QT; taper
Aripiprazole	Antipsychotic; for severe or refractory tics; the tic-licensed choice at this step	Under 50 kg: 2 mg/day, then 5 mg/day, maximum 10 mg/day. 50 kg or more: 2 mg/day, then 5 mg/day, target 10 mg/day, maximum 20 mg/day; steps no closer than a week apart	Metabolic effects, weight gain; the 5 to 20 mg/day envelope is never quoted without its bands
Risperidone	Antipsychotic; off-label for tics	Off-label; no licensed tic dose. The only figure is one trial's mean daily dose over 8 weeks, about 2.5 mg/day, and that figure carries no start, no titration and no maximum	Weight gain, hyperprolactinaemia, drug-induced movement disorders
Haloperidol	Classical agent; second-line; FDA-approved for tics	Children 3 to 12 years, 15 to 40 kg: start 0.5 mg/day, increments of 0.5 mg at 5 to 7 day intervals, divided twice or three times daily; target 0.05 to 0.075 mg/kg per day; no established maximum effective dose	Poorly tolerated; ECG monitoring essential
Pimozide	Classical agent; refractory only; FDA-approved for tics in patients who have failed standard treatment	Usual range under 10 mg per day; children start 0.05 mg/kg per day at night, raise every third day, maximum 0.2 mg/kg per day or 10 mg/day	Dose-dependent QTc prolongation; baseline ECG and potassium; CYP2D6 genotyping above 0.05 mg/kg per day; paroxetine contraindicated

Each agent's place in the sequence, its tic-indication dose where a licensed one exists and the caveat that governs its use; the behavioural first line precedes every row.

IN INDIA

The behavioural first line is the hardest part of this ladder to deliver here. Therapists trained in habit reversal and Comprehensive Behavioural Intervention for Tics are scarce outside a few academic centres, so in routine practice the active first line is often pragmatic psychoeducation, urge-awareness coaching and parent guidance built on the same principles rather than a manualised programme. One caution about the approvals named above: they are United States labelling, and the Indian licensing position for these agents was not verified for this chapter and must not be inferred from them. Where an Indian insert differs, it is the insert that governs the prescription written in India. What does travel is the order of the ladder. Reaching for a familiar antipsychotic first trades a fluctuating, often self-limiting condition for the metabolic and, with pimozide, the cardiac liabilities of a dopamine blocker, the inversion the evidence warns against.

Under 18 CLONIDINE IS NOT RECOMMENDED IN UK LABELLING	**31%** TIC REDUCTION, GUANFACINE TRIAL	**10 and 20 mg/day** ARIPIPRAZOLE TIC MAXIMUM, UNDER 50 KG AND 50 KG OR MORE	**under 10 mg/day** PIMOZIDE USUAL RANGE

34 · Differentiation of tics from stereotypies, chorea, dystonia and compulsions

A tic almost never announces itself with a label, and the child in front of you has simply been brought in for "abnormal movements", which is why the whole of this topic is a bedside discrimination and not a piece of knowledge. Tics belong to the wider family of childhood hyperkinetic movements, and the movements they are confused with - motor stereotypies, chorea, dystonia, myoclonus and, at the complex end, obsessive-compulsive rituals - each carry a treatable and prognostically different cause. Getting the movement wrong sends the child down the wrong pathway: a stereotypy worked up as a tic, a chorea missed as a habit, a dystonia treated as a quirk. The marks here are won not by naming the disorders but by knowing the single feature that pulls each one apart from a tic at the bedside.

This account owns the formal differentiation of tics from stereotypies, chorea, dystonia, myoclonus and compulsions. The diagnostic criteria of Tourette's disorder, the phenomenology of the premonitory urge and suppressibility, the classification of the tic disorders, and the management of tics each belong to their own accounts elsewhere in this chapter and are named here only as far as the discrimination needs them. Obsessive-compulsive disorder in its own right is developed in the paediatric obsessive-compulsive account; the general disorder is the Anxiety, OCD and trauma-related disorders notes'.

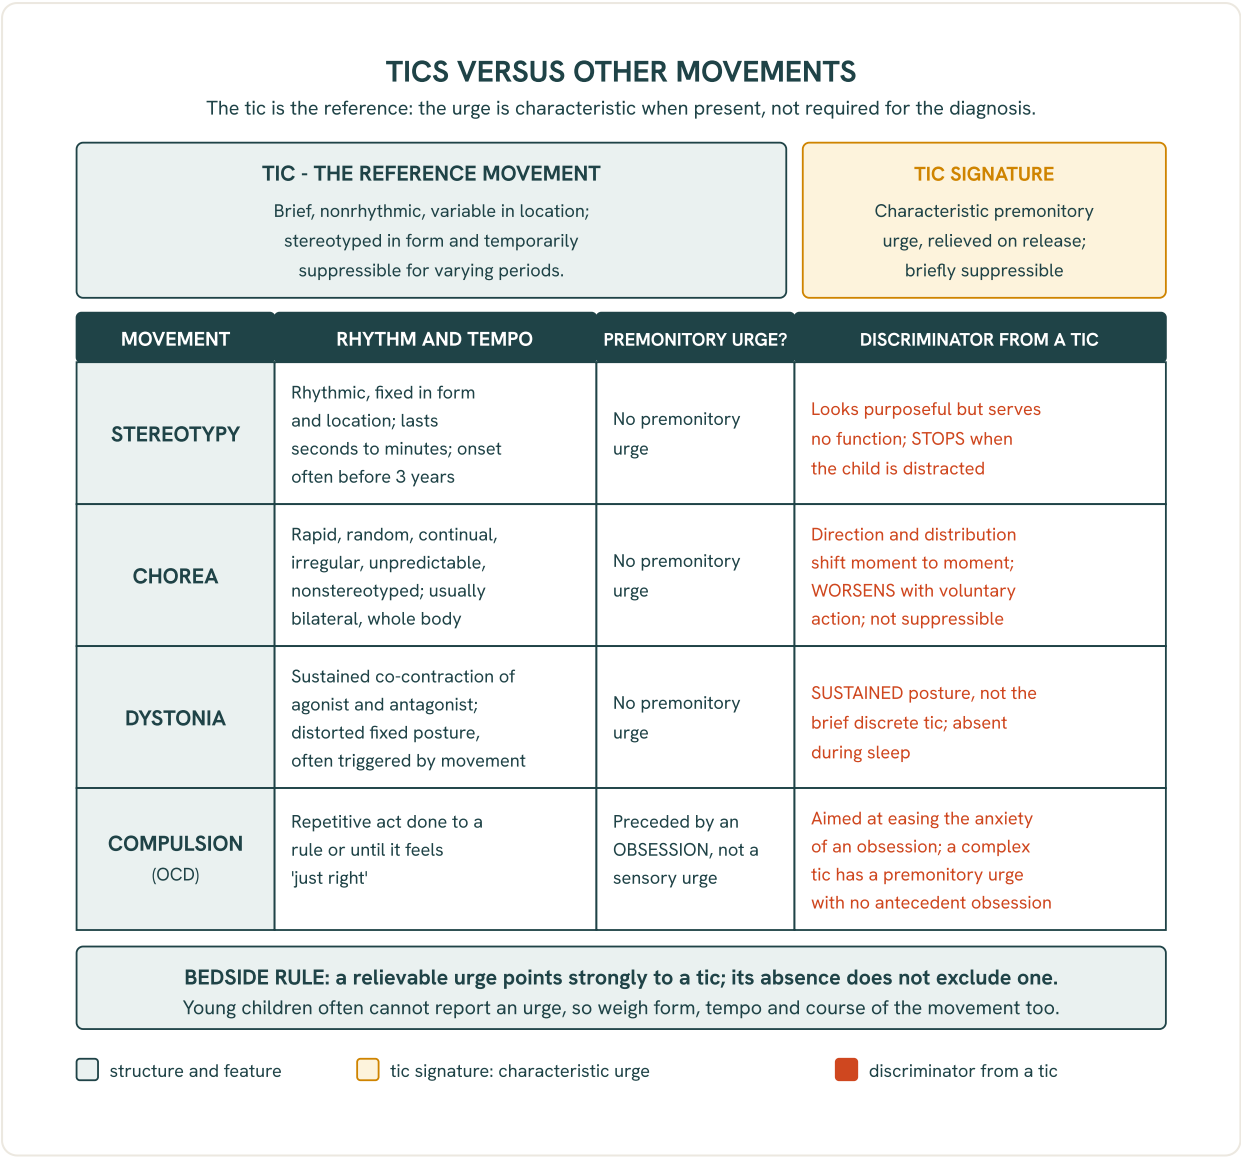

Fig 23.26. Tics versus other movements: the premonitory urge, characteristic of a tic when the patient can report it, and the brief suppressibility that goes with it, set against the discriminating feature of motor stereotypy, chorea, dystonia and obsessive-compulsive compulsion.

34.1 The signature of a tic: the reference frame for every comparison

Every discrimination below is really the same question asked six ways - does this movement carry the signature of a tic? A **tic** is a sudden, brief, non-rhythmic movement or vocalisation, and three linked features together form its signature. First, many tics are preceded by a **premonitory urge**, an uncomfortable localised sensation or inner tension that builds and is momentarily relieved by the movement; most patients old enough to describe one do, but younger children often cannot report it and not every tic carries it. Second, a tic shows partial **suppressibility**: the patient can hold it back for varying periods, at the cost of rising tension. Third, its form is stereotyped and recognisable yet its location and frequency vary over time. No other movement disorder in this differential carries all three, and a reported urge marks a movement as a tic more reliably than anything else, because it is a subjective report of an internal drive the involuntary hyperkinesias do not generate. An absent urge, though, never excludes a tic. The full teaching of the urge sits in the Tourette phenomenology account; what matters here is that you carry it as the yardstick against which each mimic is measured.

- Is there a premonitory urge, relieved by the movement? A reported urge points to a tic; the involuntary movement disorders generate none.
- Can the movement be briefly suppressed on request? A tic can; chorea and myoclonus cannot.
- Is the movement brief and non-sustained? A tic is; a dystonic posture is held.

RULE **The premonitory urge and brief suppressibility are the signature of a tic, and a positive report of them all but settles this differential.** A movement preceded by a relievable inner urge and capable of temporary suppression is a tic until proven otherwise; a movement that is purely involuntary, cannot be held back at all and carries no antecedent sensation is one of its mimics. Their absence carries far less weight: a young child may be unable to report an urge, so a negative answer sends you to form, tempo and course rather than out of the diagnosis.

MNEMONIC

Urge before, suppress on demand, brief by nature

The three-part signature in order: an **urge before** the movement that it relieves, where the patient can report one; the capacity to **suppress on demand** for a time; and a **brief, non-sustained** form. Test any suspicious movement against these three and the mimics fall away.

34.2 Tics versus motor stereotypies

This is the commonest and most examinable confusion, because both look patterned and both occur in children. **Motor stereotypies** are repetitive movements such as hand flapping, body rocking or finger wiggling that appear purposeful but serve no adaptive function. Several features separate them cleanly from tics. Stereotypies have an earlier onset, often younger than **three years**, whereas tics typically begin later in childhood. A single bout runs **seconds to minutes**, far longer than the flick of a tic. Crucially, a stereotypy is rhythmic and fixed in form and location, repeating the same movement in the same place, while a tic is brief, non-rhythmic and variable. And a stereotypy lacks any premonitory urge. The bedside discriminator that settles it is response to distraction: calling the child's name or touching them stops a stereotypy, because the child is typically absorbed and unbothered, whereas a tic is not abolished this way. Stereotypies are common in typically developing young children and more so in those with intellectual disability or autism; a child engrossed in a rhythmic, fixed pattern that a call to attention interrupts is showing a stereotypy, not a tic.

PITFALL

The costly error is to read a young child's rhythmic hand flapping or rocking as a tic and reach for a tic medication, or conversely to dismiss genuine tics as "just a stereotypy" and withhold assessment. Stereotypies rarely need pharmacotherapy and often settle with reassurance and behavioural strategies; misclassifying them exposes a child to antipsychotic or alpha-adrenergic agonist treatment they do not need. When form is fixed, onset is early and a call of the name interrupts the movement, think stereotypy before tic.

34.3 Tics versus chorea

Chorea is separated from a tic by its randomness and its relationship to movement. Chorea consists of movements that are rapid, random, continual, abrupt, irregular, unpredictable and non-stereotyped, usually bilateral and affecting all body parts, and that worsen during attempted voluntary action. Set that against the tic's signature and the contrast is sharp: a tic is stereotyped and can usually be held back for a time, and most patients able to report one describe a premonitory urge, whereas chorea has no fixed pattern, is not stereotyped, is usually bilateral across face, trunk and limbs, and its timing, direction and distribution shift from one moment to the next. The urge is asymmetric evidence and is worth using as such: a reported urge argues strongly for a tic, because the classification explicitly records the ABSENT urge for the two mimics where it states a position, stereotypies and myoclonus. It states no position on a premonitory sensation in chorea at all, so the absence of an urge argues nothing here in either direction, and against chorea the discriminators to lean on are the ones just given, its randomness, its lack of stereotypy and its worsening during attempted voluntary action. The dance-like flow of chorea across the body, flitting from limb to face to trunk without repeating itself, is nothing like the discrete, repeatable jerk of a tic. The most useful positive sign is that chorea disrupts voluntary movement, so attempts to hold a posture or perform a task fragment into extra involuntary flourishes - an active worsening rather than the tension-and-release cycle of a tic.

IN INDIA

Chorea is not an academic differential here. Sydenham chorea, the neurological manifestation of acute rheumatic fever following streptococcal infection, remains common in Indian children because rheumatic fever and rheumatic heart disease are still endemic, and it presents in the same paediatric age group in which tics appear. A new choreiform movement in an Indian child therefore mandates a search for a treatable systemic cause - a history of sore throat or migratory arthritis, examination for carditis, and the relevant work-up - rather than being logged as a tic. Missing it means missing rheumatic carditis, which is why the tic-versus-chorea distinction carries more weight here than the Western default suggests.

34.4 Tics versus dystonia

Dystonia is separated from a tic by duration and by the simultaneous pull of opposing muscles. Dystonia is the simultaneous sustained contraction of both agonist and antagonist muscles, producing a distorted posture or movement, often triggered by voluntary movement and not seen during sleep. The word to hold onto is *sustained*: where a tic is brief and non-sustained, a dystonic contraction locks the body part into an abnormal posture that is held. The co-contraction of agonist against antagonist generates that twisting, cramped quality and is mechanically the opposite of the clean single-direction flick of a simple motor tic. Two contextual features help: dystonia is frequently brought on by a particular voluntary movement, and it typically disappears in sleep. A movement that produces a held, distorted posture from opposing muscle pull is dystonia; one that is over almost as soon as it begins is a tic.

34.5 Tics versus myoclonus

Myoclonus is the supplementary movement-disorder differential, and it turns on the same two anchors. **Myoclonus** is a sudden, unidirectional, often non-rhythmic movement that may occur during sleep. It resembles a tic in being abrupt and shock-like, which is why it earns a place in the differential, but it is distinguished by its rapidity, its lack of suppressibility and the absence of a premonitory sensation or urge. Apply the signature: myoclonus cannot be voluntarily held back and carries no relievable inner urge, so both of the tic's defining subjective and volitional features are missing. That it may appear during sleep is a further pointer, locating it outside the semi-voluntary domain. When an abrupt jerk has neither an antecedent urge nor any capacity for suppression, and especially if it occurs in sleep, it is myoclonus and not a tic.

34.6 Complex tics versus obsessive-compulsive compulsions

This is the hardest separation, because a complex tic and a compulsion can look identical and the answer lies not in the movement but in what drives it. A **compulsion** in obsessive-compulsive disorder is aimed at preventing or reducing anxiety or distress and is performed in response to an obsession, for instance a washing ritual driven by a fear of contamination. A complex tic, by contrast, is driven by a premonitory urge and a need to perform the action until it feels "just right", without any antecedent obsession. The discriminating question is therefore about the antecedent: ask why the movement is done. If it neutralises a specific frightening thought, it is a compulsion; if it discharges a rising physical urge to reach a "just right" resolution with no idea being warded off, it is a complex tic. The difficulty is real, because complex tics and compulsions frequently co-occur and can be genuinely hard to separate, and many patients with a tic disorder also meet criteria for obsessive-compulsive disorder. The clinical resolution is to characterise each repetitive behaviour by its antecedent rather than by its appearance.

TRAP **Candidates try to separate a complex tic from a compulsion by how the movement looks; the discriminator is the antecedent.** Both can be elaborate, repeated and semi-purposeful, so appearance settles nothing. A compulsion answers an *obsession* and is done to reduce anxiety; a complex tic answers a *premonitory sensory urge* and is done until it feels "just right", with no frightening thought behind it. Examine the driver, not the choreography.

34.7 Putting the differential together at the bedside

Laid side by side on shared axes, the six movements separate cleanly on the two anchors and on a single cardinal feature each. The discrimination is made from a careful description of the movement and, where possible, direct observation or a home video, watching the child's response to distraction, to a request to suppress, and to attempted voluntary action.

MOVEMENT	DEFINING QUALITY	CARDINAL CONTRAST WITH A TIC
Tic	Sudden, rapid, recurrent, non-rhythmic and stereotyped, variable in location	The reference movement: urge-preceded when reportable, briefly suppressible
Motor stereotypy	Rhythmic, fixed in form and location, no urge, stops with distraction	Earlier onset and fixed pattern; interrupted by a call of the name
Chorea	Rapid, random, irregular, unpredictable, non-stereotyped; worsens with voluntary action	No fixed pattern and no urge; disrupts voluntary movement
Dystonia	Sustained co-contraction of agonist and antagonist; distorted held posture; absent in sleep	Sustained, not brief; a held abnormal posture
Myoclonus	Sudden, unidirectional, often non-rhythmic; may occur in sleep	Not suppressible and no premonitory urge
Compulsion	Performed in response to an obsession to reduce anxiety or distress	Antecedent is an obsession, not a sensory urge

The six movements of the differential on shared axes; the premonitory urge and suppressibility resolve most cases, and the final column gives the one feature that clinches each mimic.

GOOD TO REMEMBER

When a description alone leaves the movement ambiguous, do three things. Ask the older child whether a feeling builds before the movement and eases after it, since a positive report of a relievable urge is strong evidence for a tic, while a younger child unable to answer tells you nothing either way. Ask them to hold the movement back and watch for the tension-and-release of suppressibility. And observe it during an absorbing task and during a call to attention, since chorea worsens with voluntary action while a stereotypy stops when the child is addressed. A short home video often shows more than a clinic encounter.

Carry into the exam: a tic is defined by its form, sudden, rapid, recurrent, non-rhythmic and stereotyped, while the premonitory urge and partial suppressibility are its characteristic accompaniments, reported by most individuals but never required for the diagnosis - stereotypies are fixed, early-onset and stop with distraction; chorea is random and worsens with voluntary action; dystonia is a sustained held posture; myoclonus is unsuppressible; a compulsion answers an obsession while a complex tic answers a sensory urge.

Urge
CHARACTERISTIC OF A TIC, NOT REQUIRED FOR IT; RECORDED AS ABSENT IN STEREOTYPIES AND MYOCLONUS

Suppress
A TIC CAN BE BRIEFLY HELD BACK; CHOREA AND MYOCLONUS CANNOT

A TIC IS NON-SUSTAINED, UNLIKE THE HELD POSTURE OF DYSTONIA

< 3 yr
TYPICAL STEREOTYPY ONSET, EARLIER THAN MOST TICS

Elimination and feeding disorders

35 · Enuresis (types, etiology, assessment)

Bedwetting is the point at which normal development, organic disease and psychological disturbance all converge on a single symptom, and the marks are here because the candidate has to separate them. **Enuresis** is the repeated voiding of urine into inappropriate places - the bed or the clothing - in a child old enough that continence should by now have been achieved and in whom no medical cause accounts for the wetting. What makes it examinable is not the symptom, which any parent can describe, but the scaffolding around it: an age threshold below which the same wetting is developmentally normal, a frequency-or-distress requirement, a mandatory exclusion of organic disease, and a set of subtype and course distinctions that decide how the child is investigated and, later, treated.

This account owns the definition and diagnostic criteria of enuresis, its classification into subtypes, the pathophysiology that drives it, and the assessment that flows from the criteria. It does not teach the treatment: the behavioural measures, the enuresis alarm and the pharmacotherapy are taken up in their own account within this chapter, and the drug doses in particular are set out there and deliberately not restated here. Toilet-training norms and the ordinary timetable of continence belong to the Normal child development and milestones notes; what follows marks only the point at which the child has crossed from lateness into disorder.

35.1 The essential feature: Criterion A and the voiding itself

Criterion A defines the act, and it is written broadly on purpose. The requirement is the repeated voiding of urine into the bed or into clothes, and the manual is explicit that this may be either involuntary or, occasionally, intentional. The great majority of enuretic wetting is involuntary, and that is the default picture; but by admitting the rare intentional case the definition avoids excluding a child who, out of anger or protest, wets deliberately. The point behind the wording is that enuresis is defined by the event, not by the child's motive: the diagnosis turns on misplaced voiding at an age when it should not occur, and whether it was willed is a matter for formulation, not for the diagnostic threshold.

35.2 Criteria B and C: how often, for how long, and from what age

Criterion B sets the bar the wetting must clear, and it has two routes to satisfaction that candidates routinely collapse into one. The first route is one of frequency and persistence: the voiding must occur at least **twice a week** for a minimum of three consecutive months. The second route dispenses with the count altogether: even below that frequency, the diagnosis is met if the wetting produces clinically significant distress or impairment in social, academic or other important areas of functioning. A once-weekly wetter who is refusing school trips and sleepovers and is being shamed at home meets Criterion B by this second limb even though the frequency route is not reached.

The age criterion is where the diagnosis is separated from normal development. Criterion C requires that the child has reached a chronological age of at least **five years**, or, where

development is delayed, an equivalent developmental (mental) age of the same level. The floor is set at the point by which the ordinary child has established daytime and night-time control, so that wetting below it is lateness rather than disorder. Anchoring the threshold to developmental rather than chronological age matters in any child with global delay, in whom continence tracks developmental level and not birthdays: a chronologically seven-year-old functioning well below the five-year level has not failed at a task they were equipped to master, and should not be labelled.

TRAP **Reciting only "at least twice a week for three months" and forgetting the distress route.** Criterion B is satisfied by the frequency-and-duration standard OR by clinically significant distress or impairment at a lower frequency. Candidates who memorise the numeric limb alone will wrongly exclude the distressed, low-frequency wetter, who is precisely the child who reaches the clinic. The threshold is a disjunction, not a single rule.

35.3 Criterion D: the exclusion that becomes the assessment

Criterion D is a single clause that generates almost the whole of the medical work-up. The wetting must **not be attributable to the physiological effect of a substance or to another medical condition**. The substances named are the diuretics and the antipsychotics; the medical conditions span the endocrine, the structural and the neurological. Because enuresis is reached only after organic disease is cleared, the criterion is really an instruction to investigate, and the differentials it forces are the ones a careless clinician misses:

- endocrine causes of a genuine polyuria - diabetes mellitus and diabetes insipidus - in which the bladder is wet because urine output is genuinely high;
- urinary tract infection, the commonest reversible medical cause of new wetting, especially where there are daytime symptoms;
- structural anomalies of the lower urinary tract - an ectopic ureter, posterior urethral valves - which produce continuous or unusual wetting;
- neurological lesions of the spinal cord - spina bifida and a tethered cord - that disturb bladder innervation;
- a seizure disorder, where nocturnal incontinence is a manifestation of the seizure rather than of enuresis;
- an iatrogenic effect of a prescribed diuretic or antipsychotic.

RULE **Enuresis is a clinical diagnosis of exclusion made only from a defined age.** Two gates must both be passed: the child must be at least five years old chronologically or developmentally, and an organic cause - endocrine, infective, structural, neurological or drug-induced - must have been excluded. Skip either and the diagnosis is unsafe: below the age gate it pathologises normal development, and without the exclusion it renames a treatable medical illness as a behavioural one.

35.4 The subtypes by timing

The primary classification is by the time of day the wetting occurs. The condition is specified into three subtypes according to timing. The **nocturnal-only** form, in which urine is passed only

during night-time sleep, is much the commonest and is the classic monosymptomatic bedwetting of childhood. The **diurnal-only** form occurs during waking hours and, being daytime wetting, more often signals bladder dysfunction or a psychological problem. The third form combines both.

SUBTYPE	WHEN WETTING OCCURS	CLINICAL SIGNIFICANCE
Nocturnal only	Only during night-time sleep	Commonest form; typically the isolated bedwetting driven by the polyuria, bladder-capacity and arousal factors
Diurnal only	During waking hours	Daytime wetting; more likely to reflect bladder overactivity, voiding habit or emotional disturbance
Nocturnal and diurnal	Both daytime and night-time	The combined presentation, also termed the non-monosympto-matic form

The three timing-based subtypes of enuresis; the nocturnal-only form dominates in frequency, while daytime wetting shifts the differential toward bladder and psychological factors.

35.5 Monosymptomatic and non-monosymptomatic: the distinction that guides investigation

Cutting across the timing subtypes is a distinction the urological literature considers more useful still. **Monosymptomatic** enuresis is isolated night-time wetting with no daytime lower-urinary-tract symptoms - no urgency, frequency or daytime incontinence. **Non-monosymptomatic** enuresis is wetting accompanied by such daytime symptoms, and the combined nocturnal-and-diurnal subtype is the presentation this term describes. The distinction steers the work-up: the monosymptomatic child is usually the straightforward bedwetter, whereas daytime symptoms raise the suspicion of bladder pathology or infection. Within the daytime picture the manual recognises two mechanisms: **urge incontinence**, from an overactive, unstable detrusor that contracts before the child reaches a toilet, and **voiding postponement**, the habitual deferral of micturition until the bladder overflows, often in a child absorbed in play. They look alike at the moment of wetting and are told apart by the history of what precedes it.

35.6 Primary and secondary enuresis

A second course-based axis asks whether continence was ever attained. **Primary enuresis** is the form in which urinary continence has never been established, so that the wetting continues unbroken from infancy; by definition it can first be diagnosed at the age of five, the point at which the failure becomes a disorder. **Secondary enuresis** is the reappearance of wetting after a period of established dryness, its onset falling most commonly between the ages of five and eight but possible at any point in childhood. The clinically important fact is a negative one: there is no difference between the two in the prevalence of associated mental disorders, so the older teaching that secondary enuresis is the psychologically loaded form and primary the benign one is not supported. Secondary onset does, however, direct attention to what changed - a urinary

infection, a new medical illness, or a psychosocial stressor such as the birth of a sibling - because the return of wetting in a previously dry child asks for an explanation.

PITFALL

Treating new-onset secondary wetting as a behavioural relapse without asking what precipitated it. Because the child was previously dry, a fresh medical cause - a urinary tract infection, newly manifest diabetes with its polyuria - or an acute psychosocial stressor is likelier than in the never-dry child. Reaching for a behavioural programme skips the step that matters most in the secondary case: looking for the treatable thing that ended the child's dryness.

35.7 Epidemiology: common, male-predominant, and self-limiting

Enuresis is one of the commonest disorders of childhood, and its epidemiology is defined by a steady fall with age. Community prevalence of night-time wetting runs at around **5 to 10% at age five**, declining to 3 to 5% by age ten and to about 1% by age fifteen and beyond. The trajectory is the teaching point: prevalence falls year on year because the condition remits spontaneously in most children, so what is near-normal at four becomes, in the adolescent, uncommon and clinically weighty. Across these figures boys carry the higher prevalence, one of the more reliable features of the disorder.

5 to 10%	3 to 5%	about 1%	5 to 10%
PREVALENCE AT AGE FIVE	PREVALENCE AT AGE TEN	AT AGE FIFTEEN AND OLDER	REMIT SPONTANEOUSLY EACH YEAR AFTER FIVE

35.8 Etiology: three pathophysiological strands

The modern understanding of nocturnal enuresis is not one cause but the convergence of three, and a given child may sit on any one or a combination of them. The first is a mismatch between how much urine the kidney makes at night and how much the bladder can hold: a blunted nocturnal rise in arginine vasopressin, the antidiuretic hormone whose secretion normally climbs overnight to concentrate the urine, allows an overnight nocturnal polyuria that overwhelms the sleeping bladder. That this pathway is real is shown by vasopressin-deficient children becoming dry when the hormone is replaced, and by responders and non-responders differing in their vasopressin profile. The second strand is the bladder itself: a low **functional bladder capacity** with an unstable, overactive detrusor means the bladder signals fullness and empties at a smaller volume than it should, and a low functional capacity is a recognised predictor of failure to respond to the enuresis alarm.

The third strand frames enuresis as a **disorder of arousal**: the enuretic episode characteristically arises out of deep, delta-wave sleep, and the child fails to wake to the signal of a full or contracting bladder. Sleep studies bear this out - enuretic children received the arousal signal yet did not respond by waking - which reframes the wetting as a failure of arousal rather than of bladder or kidney alone. Voiding occasionally occurs in rapid-eye-movement sleep, when the child may later recall a dream of micturition, but the core deficit is the failure to arouse. The three strands are not rivals: a single child may carry mild polyuria, a modest reduction in bladder

capacity and a high arousal threshold together, and it is their combination that produces the wet bed.

MNEMONIC

Too much water, too small a bladder, too deep a sleep

The three etiological strands of nocturnal enuresis in a line. **Too much water**: the blunted overnight vasopressin rise and its polyuria. **Too small a bladder**: low functional bladder capacity with detrusor overactivity. **Too deep a sleep**: the failure to arouse from delta sleep to the bladder's signal. Any one may dominate, and most children carry a mixture.

35.9 The genetic contribution

Enuresis runs in families, and the familial loading is one of the strongest of any childhood disorder. A child's risk is substantially raised by a parental history: it is about **7.1 times** greater where the father was himself enuretic beyond early childhood, and about 5.2 times greater with a corresponding maternal history, and enuresis is correspondingly commoner in children with an affected parent. The heritability is high enough that a positive family history is both a useful diagnostic pointer - it reassures the family that the mechanism is constitutional rather than wilful - and a fair predictor that the child, like the parent before them, will in time grow out of it. The inherited component is best understood as acting through the mechanisms already described, shaping the overnight hormone rhythm, the bladder's functional capacity and the depth of sleep, rather than as a separate cause standing apart from them.

35.10 Assessment: history and examination first, investigation guided

The assessment is driven entirely by the criteria, and its architecture follows Criterion D. The history establishes the pattern - night, day or both; monosymptomatic or carrying daytime urgency, frequency and incontinence; primary or secondary, since a previously dry child who has begun to wet again is investigated differently from one who was never dry. It quantifies frequency and the distress caused, both of which the diagnosis needs, and takes the informative family history. The examination looks for the structural and neurological signs the exclusion criterion demands, the lumbosacral spine and perineal neurology especially. Investigation is then targeted rather than routine: a urinalysis for the glycosuria of diabetes and the pyuria of infection, with imaging or specialist referral reserved for the child whose daytime symptoms, abnormal stream or examination findings point to structural or neurological disease. A frequency-volume record of daytime voids and overnight wetting is the single most informative bedside tool, exposing both the true nocturnal urine output and the functional bladder capacity, and so pointing to which strand is operating.

GOOD TO REMEMBER

Two cheap steps carry most of the assessment. A urine dipstick excludes the two organic causes that must never be missed - the glycosuria of new diabetes and the leucocytes and nitrites of infection - and a few days of a home frequency-volume chart distinguishes the small-capacity bladder from the polyuric night and flags the daytime symptoms of non-monosymptomatic disease. Both precede any referral and turn a vague complaint of bedwetting into a mechanism you can act on.

35.11 Course, prognosis, and the line with normal development

The natural history is favourable and is itself part of the teaching. After the age of five the condition remits without treatment in a substantial share of children each year - on the order of 5 to 10% annually - so the pool shrinks steadily through childhood, and only about 1% of cases persist into adulthood. This high spontaneous remission is why treatment is weighed against watchful waiting, and why the alarm and drug measures are held for the child in whom wetting is causing real distress or failing to resolve. It also fixes the boundary with normal development: below the age of five, or below the equivalent developmental level, night-time wetting is a normal stage of a not-yet-complete process and is not enuresis at all. The disorder begins where the developmental grace period ends, which is why the age criterion, not the wetting, is the true threshold.

Enuresis is diagnosed only from a chronological or developmental age of five years, requires wetting at least twice a week for three months or else clinically significant distress, and is a diagnosis of exclusion made only once organic causes are ruled out.

35.12 ICD-11 and how the two systems differ

The two classifications agree on the concept but differ sharply in how they quantify it. Where the manual sets a numeric threshold, ICD-11 describes the frequency in words: enuresis is the repeated and persistent voiding of urine into the bed or clothes, occurring, in its wording, several times per week over several months, rather than the quantified twice-weekly-for-three-months standard of the manual. The age concept is expressed developmentally - continence is expected at a developmental age approximately equivalent to a chronological age of five years - and the same three timing subtypes are retained. The practical consequence is that the diagnosis rests on the descriptive "persistent and repeated" wording and on clinical judgement of what counts as developmentally overdue, rather than on a hard count, while the concept, the subtypes and the exclusion of organic disease are held in common with the manual.

IN INDIA

Because services here classify under ICD, the operative entity in the case file and the referral is the ICD one, coded 6C00, and the clinician diagnoses from its descriptive frequency and developmental-age wording rather than from a numeric manual threshold. The presentation is shaped by local realities: bedwetting is frequently normalised or, conversely, punished within the family, help-seeking is often delayed until an older child faces the shame of shared sleeping arrangements or a school trip, and the first port of call is usually the paediatrician rather than the psychiatrist. The clinician's early task is often as much to relieve the blame heaped on a constitutionally predisposed child, whose parent likely wet the bed too, as to investigate.

36 · Management of enuresis (behavioural, bell-and-pad alarm, desmopressin, imipramine)

The marks here sit on a sequence and a safety trap, not on a catalogue of drugs. What follows assumes the child has already been worked up, an organic and a daytime-symptom cause excluded, and the diagnosis of primary nocturnal enuresis secured. From that point the whole of management turns on two ideas. The first is that the least medical option is also the most durable, so the child who can wait is better served by conditioning than by a tablet. The second is that the one genuinely dangerous drug on the ladder is dangerous because the dose that works is so small.

Stated as a single sentence, the rational sequence is **behavioural intervention** first, with the enuresis alarm as its most durable member; then **desmopressin** as the drug reached for most often when a rapid pharmacological effect is needed; and **imipramine**, the **tricyclic antidepressant**, held back for refractory individuals. The classification and causal story upstream belong to the companion account of enuresis.

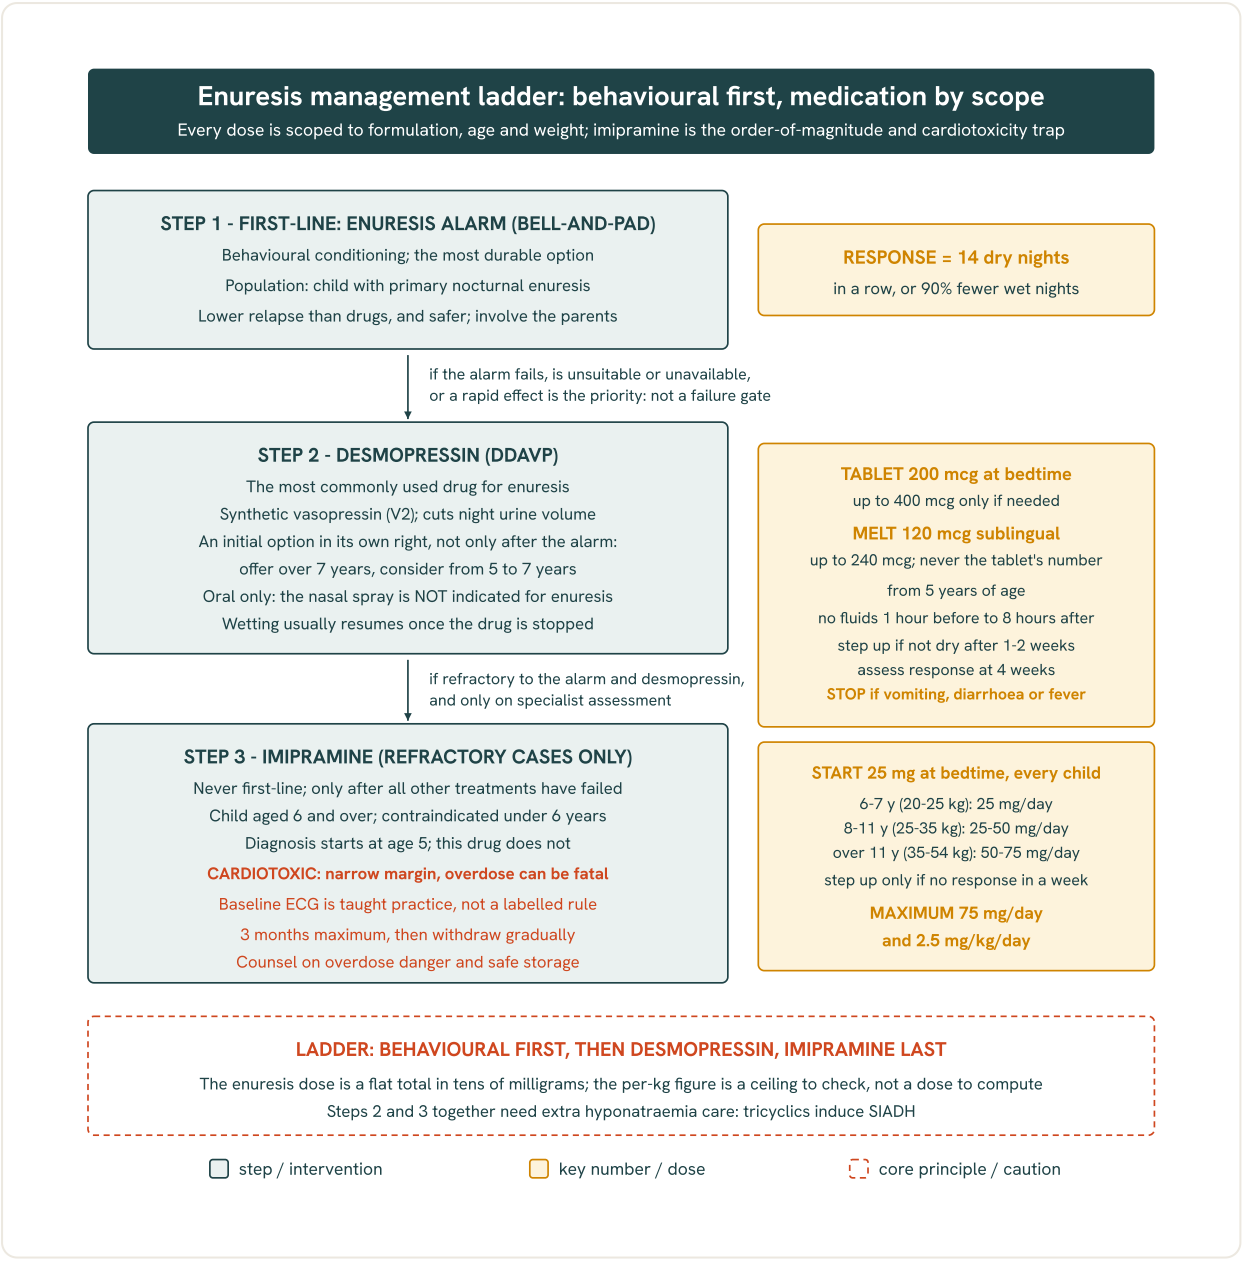

Fig 23.27. Enuresis management ladder: the bell-and-pad alarm is first-line and the most durable option, its benefit outlasting treatment where the drugs' does not, and a response is 14 consecutive dry nights or a 90 percent reduction in wet nights per week; desmopressin is the most-used drug and an initial option in its own right when a rapid effect is the priority or an alarm is unsuitable, given from 5 years of age as a 200 to 400 microgram tablet or a 120 to 240 microgram sublingual melt at bedtime, with fluids withheld from 1 hour before the dose until 8 hours after it, the dose stepped up in the child not completely dry after 1 to 2 weeks and the response assessed at 4 weeks, and the drug stopped during vomiting, diarrhoea or any acute illness upsetting fluid or electrolyte balance until the child is well again; and imipramine is reserved for the refractory child of 6 and over, started at 25 milligrams at bedtime, banded by age and weight, and never taken above 75 milligrams a day or 2.5 milligrams per kilogram per day, for no more than 3 months.

36.1 The ladder, and why its order is the answer

The order encodes a judgement about durability, safety and speed, in that priority. A graded approach begins with the recognition that many children become dry without any active treatment as they grow, so the first duty is to do no harm, to demystify the problem for a family that is often frightened and blaming, and to lift the shame that surrounds it. Against that background the least invasive effective option is preferred, and only when it fails or cannot be used does the clinician step up. A drug is added when the family needs a result faster than

conditioning can deliver it, for instance to get a child through a school trip or a family stay, and here desmopressin is the usual choice. The ladder is a priority order, though, not a queue in which each rung must fail before the next may be touched: desmopressin is an initial treatment in its own right, offered to the child over 7 years, and considered from 5 to 7 years, whenever a rapid or short-term improvement is the priority or an alarm is inappropriate or undesirable. The tricyclic is the one rung that genuinely is gated: it sits at the bottom, not because it does not work, but because it is no longer a first-line pharmacological choice and is reserved for refractory cases, and it is considered only for the child who has not responded to all other treatments and who has been assessed by a clinician with expertise in bedwetting, its cardiotoxicity making it the wrong drug to reach for early.

RULE **Conditioning teaches, drugs only suppress.** The alarm changes what the sleeping bladder does with a full-bladder signal, so its benefit can outlast the treatment; desmopressin and imipramine act only while they are being taken, and wetting characteristically returns once they are stopped. This single distinction is why the alarm leads the ladder and why a drug alone is a holding measure rather than a cure. When a family wants the wetting to end for good, the answer bends toward conditioning; when they want it to pause for a fixed occasion, the answer bends toward a drug.

MNEMONIC

First the bell, then the hormone, last the amine

The **bell** is the bell-and-pad alarm at the head of the ladder; the **hormone** is desmopressin, the vasopressin analogue, as the commonest drug; the **amine** is the tricyclic imipramine, kept last for the refractory child. The order of the phrase is the order of escalation, and it also tracks safety.

36.2 The behavioural foundation before any device or drug

Simple measures resolve a meaningful share of cases and make every later step work better. Before an alarm is fitted or a prescription written, a set of general behavioural measures is put in place, and in the milder or younger child they may be all that is needed.

- Motivational and educational work with the child and family, reframing the wetting as an involuntary developmental lag rather than laziness or defiance, which removes the punishment that entrenches it.
- Fluid and voiding scheduling: adequate daytime drinking, tapering intake in the evening, and a reliable bladder emptying at bedtime.
- Simple positive reinforcement of dry nights, the star-chart family of methods, in which the child records and is rewarded for success rather than blamed for failure.
- Bladder-training and lifting or scheduled-waking strategies in selected children, layered on when the basic measures are insufficient.

This is the substrate on which the alarm succeeds: a child who is engaged, unpunished and motivated will persist with a demanding conditioning programme, and a punished, ashamed

child will abandon it. It carries no risk at all, which is why it is never skipped even when a drug is going to be used.

36.3 The bell-and-pad alarm: the most durable single treatment

The alarm is a conditioning device, and its case rests on durability rather than on a headline success rate. The **bell-and-pad, or enuresis alarm**, works by classical conditioning: a moisture-sensitive sensor triggers a loud alarm at the very start of voiding, the child wakes and completes the void in the toilet, and over repeated pairings the sensation of a full bladder comes to substitute for the alarm as the waking or inhibiting signal. It is the first-line treatment once advice on fluids, toileting and an appropriate reward system has not worked, and its standing on the ladder rests on three comparative facts.

The first is that it gives up nothing while it is running: set against desmopressin, there is little or no difference in the number of children reaching a response by the end of treatment. The second is where the difference actually lies. Once treatment stops, the alarm may leave more children dry at follow-up than desmopressin does, and against imipramine the contrast is starker still, because the tricyclic's effect is not sustained after withdrawal and most children relapse. That persistence is the durability the drugs cannot match. The third is safety, and it is mechanical rather than statistical: a conditioning device cannot cause a hyponatraemic convulsion and cannot be taken in overdose.

One honest caution about the figures. The success percentages that older textbooks still print for the alarm come from reviews that the current Cochrane updates have replaced, and they move a great deal with how success was defined in the first place. The current reviews report relative effects on low-quality evidence and name no single success rate, and NICE says only that alarms have a high long-term success rate. What NICE does give is a definition rather than an effect estimate: a response is **14 consecutive dry nights**, or a **90 percent** improvement in the number of wet nights per week. The response to an alarm is assessed by 4 weeks, and treatment is stopped only if there are no early signs of response at all.

The alarm's chief limitation is that it demands sustained effort over weeks from an already tired family. Two features predict that it will fail: a low **functional bladder capacity**, and an inability to be aroused from sleep.

> **PITFALL**
>
> The commonest way the alarm fails in practice is not that it does not work but that it is abandoned too soon. Families expect a quick result, hear the alarm wake the whole household for several nights running with no dry mornings, and give up before the conditioning has had time to consolidate. Counselling that the method takes weeks of consistent use, and that early alarms without dry nights are the process working rather than failing, is what makes the device work.

36.4 Desmopressin: what it is and what it does

Desmopressin is a hormone analogue, not a sedative or a bladder drug. Desmopressin acetate, or DDAVP, is the most commonly used pharmacological intervention for primary nocturnal

enuresis. It is a synthetic vasopressin V2-receptor analogue that acts on the renal collecting duct to concentrate the urine and so reduce the volume of urine produced overnight. Because the drug corrects the water-handling rather than teaching the bladder anything, its effect is entirely dependent on continued administration. Wetting typically resumes once the drug is stopped, and the durable benefit off treatment is correspondingly low: on current evidence the alarm may leave more children dry at follow-up than desmopressin does. Against placebo the drug may reduce wet nights by roughly one to two a week, on low-certainty evidence, and probably increases the chance of achieving 14 consecutive dry nights, RR 3.18 (95% CI 1.75 to 5.80), on moderate-certainty evidence, and a raised chance of an endpoint is not a dry night promised to a particular child on a particular night. Guidance requires the family to be told, in these terms, that many children but not all will experience a reduction in wetness, and that many but not all will relapse when the drug is withdrawn.

36.5 Desmopressin: route, formulation and dose

Route is now a safety decision, and the oral route has won it. Desmopressin can be given intranasally or orally, and the modern position is that the oral route is preferred. The nasal spray is not a deprecated option but a withdrawn one: it is not an indicated formulation for primary nocturnal enuresis at all, because postmarketing reports showed a higher risk of hyponatraemia and hyponatraemic convulsions with the nasal spray than with desmopressin tablets. There is therefore no current bedtime nasal dose to carry for this indication.

The tablet and the melt are different strengths, and giving one the other's number is the error to avoid. Oral desmopressin is for the child from 5 years of age with normal urine-concentrating ability. The plain tablet is started at **200 micrograms at bedtime and increased to 400 micrograms** only if the lower dose proves insufficient, and the timing of that step matters: **the increase is considered in the child who is not completely dry after 1 to 2 weeks of the initial dose**, and **the response is assessed at 4 weeks**, **treatment being continued for 3 months** where there are signs of one and stopping considered where there are none. The sublingual melt is a different preparation at a different strength: it is started at **120 micrograms sublingually at bedtime and increased to 240 micrograms**, because 120 micrograms of melt is bioequivalent to 200 micrograms of tablet. Write the tablet's number on a melt prescription and the child receives about one and two-thirds of the intended exposure of the drug whose signature harm is a dose-dependent hyponatraemic convulsion. One jurisdictional divergence matters: United Kingdom labelling caps the tablet at 400 micrograms, while United States labelling permits titration to a higher maximum at bedtime. The lower ceiling is the one carried here. Continued treatment is not open-ended either: the need for it is reassessed after 3 months by means of a period of at least a week without the drug.

36.6 Desmopressin: the hyponatraemia caution that governs its use

The whole safety profile of desmopressin reduces to one preventable event. The most serious, if rare, adverse effect is **hyponatraemia**, and it can progress to seizures. It is the direct pharmacological consequence of the drug's action: a V2-mediated water retention that, if the child then drinks freely, dilutes the serum sodium into a dangerous water intoxication. The

management follows from the mechanism, and the rule is a window of time rather than an allowance of volume: **fluid intake must be limited to a minimum from 1 hour before the dose until the next morning, at least 8 hours after it**. Treatment without that reduction in fluid may lead to water retention and hyponatraemia, with or without the warning signs of headache, nausea and vomiting, weight gain and, in severe cases, convulsions; if they appear, treatment is interrupted until the child has fully recovered and the fluid restriction is enforced strictly on restarting. That symptom-triggered stop is the later of two stop rules. The tablet's labelling requires it to be discontinued during an episode of vomiting or diarrhoea until the child's fluid balance is once again normal, and the melt's labelling requires treatment to be interrupted during any acute intercurrent illness characterised by fluid or electrolyte imbalance, systemic infection, fever and gastroenteritis being the named examples. The fluid window and the warning signs both assume a well child drinking to a rule. The sick child has already lost control of his fluid and electrolyte balance, is being rehydrated by an anxious parent, and is on a drug that holds that water in, so waiting for the headache or the weight gain is waiting too long. The sick-day rule is therefore a second instruction of equal rank, not a footnote to the window. In a country where childhood gastroenteritis is common it is the more frequently needed of the two rules, and it is the one families are least often given. The same labelled warning tells the child to avoid swallowing water while swimming. Desmopressin must not be used in a child with primary or psychogenic polydipsia, in whom the compulsion to drink removes the one safeguard the treatment depends on; the polydipsia and any alcohol misuse are excluded before the drug is prescribed, not after. Desmopressin is a safe and useful drug whose single real hazard is entirely avoidable by a rule the family can follow.

Two further points belong to the rule rather than to the laboratory. Routine measurement of weight, serum electrolytes, blood pressure or urine osmolality is not recommended in the child treated with desmopressin for bedwetting, which puts the whole weight of safety on two spoken rules and no blood test: the fluid window on a well night, and the sick-day stop on any night that is not one. And there is one interaction: drugs that induce inappropriate antidiuretic hormone secretion, tricyclic antidepressants expressly among them, demand extra precautions against hyponatraemia when given with desmopressin, including careful attention to the fluid restriction and more frequent monitoring of the serum sodium.

GOOD TO REMEMBER

The instructions that actually prevent harm are not written on the prescription, they are spoken to the parent, and there are two of them. The first is a clock rather than a cup: drinks stop an hour before the tablet and do not resume until the morning. Teaching an allowed volume instead invites the family to give that allowance at two in the morning, deep inside the antidiuretic window. The second is the sick day: no dose on a night the child is vomiting, has diarrhoea or is febrile, and none again until he is well and his fluid balance is normal. Pair every prescription with both, instruct the parents explicitly to keep to them, and withhold the drug entirely from the compulsive drinker.

36.7 Imipramine: the tricyclic, and the order-of-magnitude dose

The imipramine enuresis dose is measured in tens of milligrams total, and this is the single most examined trap in the topic. Imipramine has a long history in this indication, and Indian pharmacology teaching lists enuresis among its uses. The age floor is the first thing to get right, because it is not the diagnostic floor: **the drug is for the child of 6 years and over, and it is contraindicated below 6**, whereas the diagnosis may be made from a chronological or developmental age of 5. The five-year-old who meets criteria is a child you may diagnose and must not give this drug to.

Every child starts at the same place, 25 milligrams at bedtime, whatever the age, and the dose is then set by age and weight band: **25 milligrams a day at 6 to 7 years and 20 to 25 kilograms, 25 to 50 milligrams a day at 8 to 11 years and 25 to 35 kilograms, and 50 to 75 milligrams a day over 11 years and 35 to 54 kilograms**. If a satisfactory response has not come within a week, the dose is stepped up, and it is stepped up slowly, because starting low catches the child who responds low. Two ceilings bound the indication: **75 milligrams a day in total, and 2.5 milligrams per kilogram per day**, whichever is reached first. The labelling is explicit that a daily dose above 75 milligrams does not enhance efficacy and tends only to increase side effects.

The rule is this: the enuresis dose is tens of milligrams as a total daily amount, and it is never converted into, nor borrowed from, a per-kilogram antidepressant figure. Outside nocturnal enuresis, imipramine has no established paediatric safety or efficacy at all; enuresis is the only childhood indication the drug holds. The enuresis dose is small on purpose.

TRAP **Do not read the enuresis dose as milligrams per kilogram.** The classic error writes the imipramine enuresis dose as a per-kilogram quantity, or imports a per-kilogram antidepressant envelope from elsewhere. The enuresis dose is a flat total of tens of milligrams, and the per-kilogram figure that exists in this indication is a cap of 2.5 milligrams per kilogram per day, not a target. A thirty-kilogram nine-year-old dosed to a per-kilogram misreading reaches a three-figure daily dose in a child whose labelled maximum is 75 milligrams.

36.8 Imipramine: cardiotoxicity, overdose and the safeguards

The reason imipramine is held back is a narrow margin between the effective and the fatal. The tricyclic has a **narrow therapeutic index**, and children, the poorly hydrated and those with cardiac disease are more susceptible to its cardiotoxicity than healthy adults. It prolongs the QTc interval and slows cardiac conduction, and in overdose it may be fatal, producing convulsions, cardiac dysrhythmias, severe hypotension, central nervous system depression, coma and characteristic ECG changes. The danger is compounded by the small effective quantity: the tablets a family holds are a plausible instrument of accidental poisoning by a younger sibling, or of a school-aged child's magical belief that swallowing the whole bottle will cure the bedwetting faster. For these reasons the drug must be dispensed and stored under control.

The monitoring follows the cardiac risk. A baseline electrocardiogram before starting is a widely taught practice point rather than a labelled requirement; neither the United Kingdom nor the United States labelling mandates one. What the labelling does record is the reason the ceiling sits where it does: electrocardiographic changes of unknown significance have been reported in

children given twice the maximum of 2.5 milligrams per kilogram per day. There is no per-kilogram threshold above which monitoring is switched on, and any such trigger set above the maximum would only ever fire outside the dose range the drug is allowed to occupy. The cap is the control, not the monitor.

Exposure is capped in time as well as in dose: the maximum treatment period is 3 months, including a gradual withdrawal, and the drug is never stopped abruptly. If the child relapses, a further course is not begun until a full physical examination has been made, and the child who needs repeated courses is reviewed medically every 3 months. The counselling is part of the safety: the family is told that the course lasts 3 months, that the dose is raised gradually, that it is taken at bedtime, that more than two out of three children relapse afterwards, and, in terms, about the particular dangers of overdose and the importance of giving only the prescribed amount and storing the tablets safely. A time-limited course is the control that stops an indefinite exposure to a cardiotoxic drug in a condition that most children grow out of anyway. Imipramine's toxicity is the whole reason it has fallen to the foot of the ladder even though it is an effective drug. It earns its place only in the refractory child in whom the safer options have genuinely been tried and have failed.

36.9 Choosing and combining, and the Indian reality

The three modalities are not interchangeable; each answers a different clinical question.

MODALITY	MECHANISM	DURABILITY OFF TREATMENT	CHIEF HAZARD	PLACE ON THE LADDER
Behavioural measures and the bell-and-pad alarm	Classical conditioning of the full-bladder signal	Highest: the benefit can outlast the treatment	None of consequence; demands weeks of effort	First-line; the most durable single treatment
Desmopressin	Vasopressin V2 analogue reducing nocturnal urine volume	Low: wetting typically resumes on withdrawal	Hyponatraemia and water intoxication; needs the fluid window	The commonest drug; for a rapid or occasion-limited effect, and an initial option when an alarm is unsuitable
Imipramine	Tricyclic; anticholinergic and other actions on the bladder	Low; relapses on withdrawal	Cardiotoxicity, lethal in overdose; dose and duration both capped	Reserved for refractory cases after specialist assessment; no longer first-line

The three treatments compared; the accompanying figure sets out the same escalation from behavioural methods through desmopressin to the reserved tricyclic.

The alarm and desmopressin are not mutually exclusive and are deliberately combined, the drug giving the family early dry nights that sustain their motivation to persist with the conditioning. Where bedwetting has not responded to an initial course of the alarm, the combination of alarm and desmopressin is offered, or desmopressin alone if continuing with the alarm is no longer acceptable to the family. The combination to think twice about is the other one: because tricyclic

antidepressants are among the drugs that induce inappropriate antidiuretic hormone secretion and so demand extra hyponatraemia precautions alongside desmopressin, the second and third rungs of this ladder interact. An anticholinergic is not offered in combination with imipramine.

IN INDIA

The ladder as taught is Western in its ordering, but the Indian reality tilts practice toward the drugs. Enuresis alarms are not widely available or affordable in most settings, so the behavioural first line, though correct, is often not a real option. That is not a licence to skip to the tricyclic. An alarm that cannot be obtained is exactly the case the guidance already anticipates: where an alarm is inappropriate or undesirable, desmopressin is offered as an initial treatment in its own right. Desmopressin as a bedtime oral tablet is therefore the pragmatic pharmacological choice, paired always with the fluid window. Imipramine, by contrast, is inexpensive, familiar and long-established in Indian teaching, where the standard pharmacology texts list enuresis among its uses, and that reachability is precisely why the cardiotoxicity caution matters more here, not less: the safeguards of a controlled supply, a capped dose and a time-limited course are easiest to neglect where the drug is easiest to get.

The doses in this account are taken from United Kingdom and United States labelling, read directly. The Indian regulatory position was not verified: no CDSCO-approved package insert for imipramine or desmopressin was consulted, and no claim is made here about what an Indian insert licenses, at what age, or at what ceiling. Where an Indian insert differs from the figures above, it is the insert that governs the prescription written in India.

The one line to carry: behavioural methods and the alarm are first-line and most durable, desmopressin is the commonest drug and an initial option in its own right when speed matters or an alarm is unsuitable but it relapses on withdrawal, and imipramine is a reserved, cardiotoxic drug for the child of 6 and over whose enuresis dose is a flat tens of milligrams capped at 75 a day, never calculated per kilogram. The per-kilogram figure is a ceiling, not a dose to compute from, and both caps bind and the first one reached is the one that governs.

14 dry nights	**200 to 400 mcg**	**120 to 240 mcg**	**75 mg/day**
IN A ROW, OR A 90% DROP IN WET NIGHTS: THE NICE RESPONSE	DESMOPRESSIN TABLET, AT BEDTIME	DESMOPRESSIN MELT, SUBLINGUAL	IMIPRAMINE MAXIMUM, AND NEVER ABOVE 2.5 MG/KG/DAY

37 · Encopresis (types, etiology, management)

The soiling that brings a child to the clinic is almost never the wilful act it is first taken to be, and the whole of this topic turns on that correction. **Encopresis** is the repeated passage of faeces into places where it does not belong, into the clothing or onto the floor, whether the child intends it or not. It is coded in the manual as F98.1, and it is examinable less for the wording of its criteria than for the physiology hidden beneath them: in most affected children the soiling is the visible end of a long chain that begins with one painful stool and ends with liquid faeces leaking helplessly around a hard, retained mass. Read that way, encopresis stops being a

behavioural problem and becomes a disorder of retention with a behavioural surface, and its whole management follows from that reframing.

This account owns the diagnostic criteria of encopresis, its subtypes, its epidemiology, the retention-constipation mechanism that generates the common form, and the staged treatment that flows from that mechanism. The parallel elimination disorder of the bladder, and the drug treatment of that disorder, are taught in their own accounts elsewhere in this chapter and are named here only where the contrast teaches something; the full paediatric assessment framework belongs to the Child psychiatry: assessment, treatment, services and protection notes.

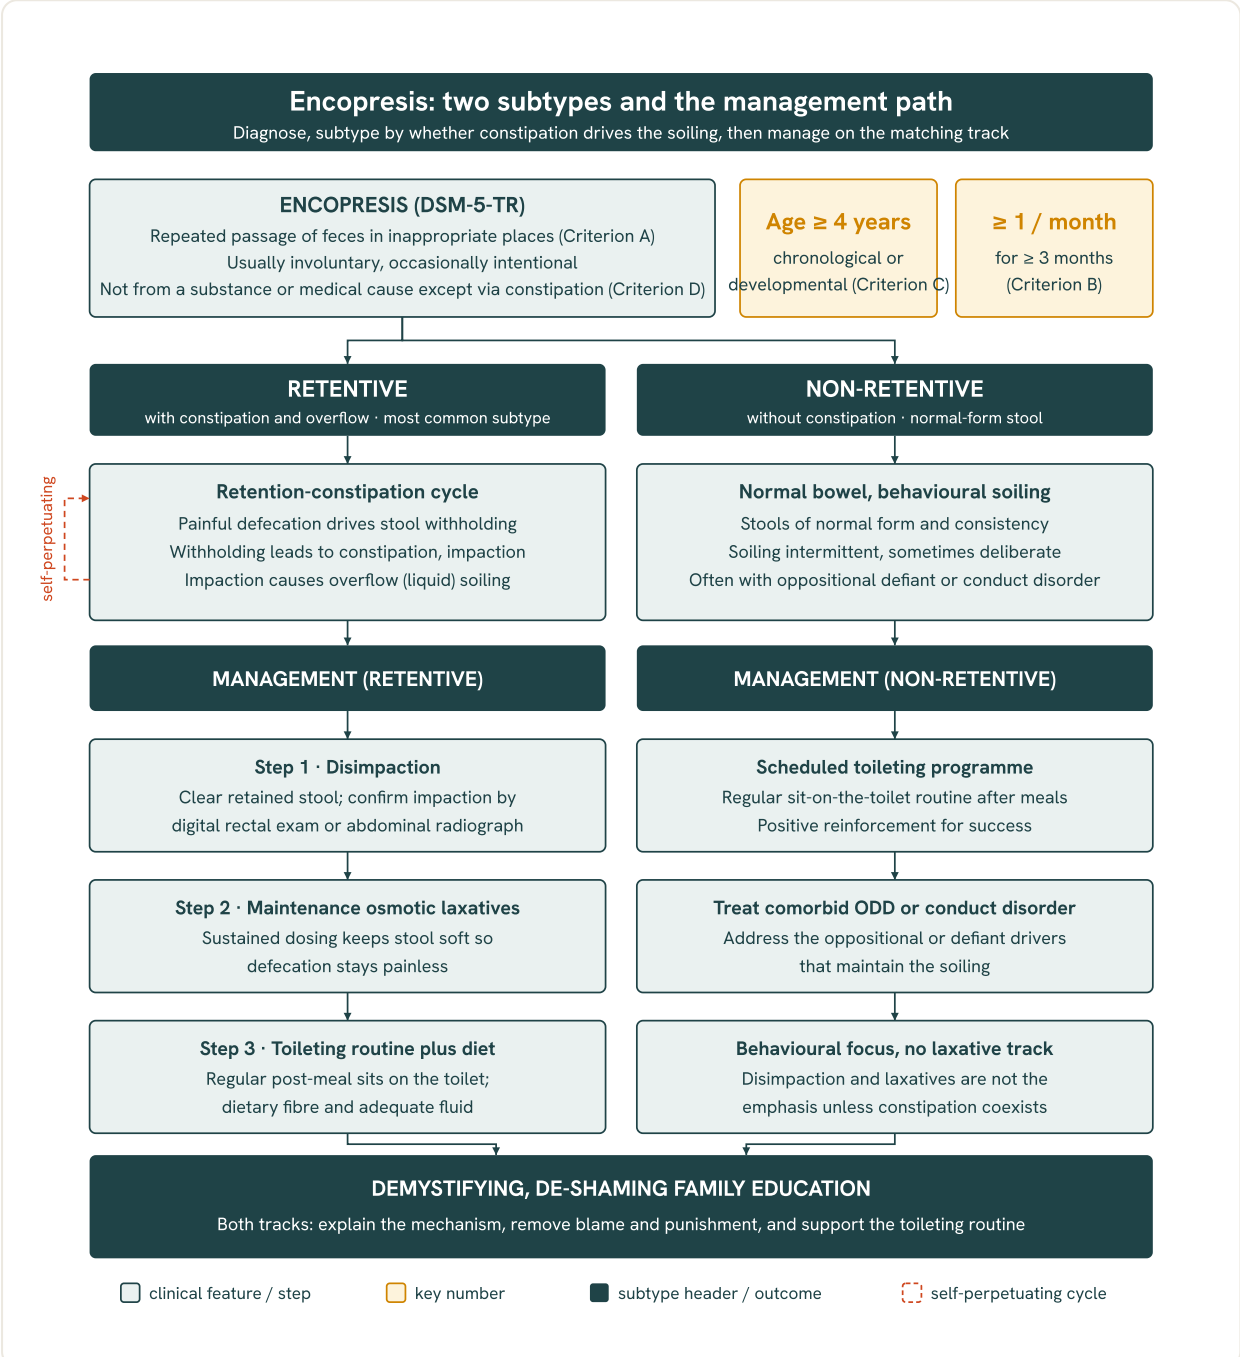

Fig 23.28. Encopresis subtypes and management: a shared DSM-5-TR diagnosis splits into a retentive track (constipation with overflow, managed by disimpaction, maintenance osmotic laxatives, and a toileting routine) and a non-retentive track (normal-form intermittent soiling, managed behaviourally and by treating comorbid oppositional defiant or conduct disorder), converging on demystifying family education.

37.1 Criterion A: the act, and why intent is beside the point

The defining feature is the repeated passage of faeces into inappropriate places, and the criterion is written to be neutral about whether the child meant it. The manual specifies that the passage is most often involuntary and only occasionally intentional, and this ordering is the clinically important part. A tired parent, and sometimes a hurried clinician, reads soiling as defiance, laziness or a bid for attention, because a school-aged child who fouls their clothes surely could stop if they wished. The criterion refuses that reading. In the great majority the child does not feel the stool coming and cannot hold it back, because a retained mass has blunted the normal call to stool and the liquid overflow slips past without warning. Occasionally the passage is deliberate, and that minority carries its own diagnostic weight, discussed with the subtypes below, but the default assumption in front of a soiling child is that the act is involuntary, and getting that starting assumption right is what separates a clinician who treats the bowel from one who punishes the child.

37.2 Criteria B and C: the frequency threshold and the age gate

Two criteria convert a symptom into a disorder: a minimum frequency and duration, and a minimum age. Criterion B sets the count. There must be **at least one such event each month**, sustained for **at least three months**. The threshold is deliberately low, because even monthly soiling in a school-aged child is not a variant of normal, and the three-month floor keeps a single episode of illness-related soiling from being over-labelled. Criterion C is the developmental gate, and it is the one candidates most often state loosely. The child must have reached a chronological age, or an equivalent developmental level, of **at least four years**. The gate is developmental, not merely chronological: continence is a milestone, and a child whose global development sits below the four-year level has not yet reached the stage at which reliable bowel control is normally expected, so the label cannot be applied to them however old they are in calendar years. This matters acutely in a population where intellectual disability and global delay are common, and it is the reason the developmental age, not the birth certificate, decides eligibility.

RULE **Encopresis is a diagnosis of the child who has, developmentally, arrived at continence and then lost or never consolidated it.** The age criterion is a floor set at the point where bowel control is normally achieved, and it is expressed as a developmental level rather than a birthday precisely so that a delayed child is not mislabelled for failing a task their nervous system has not yet reached. Establish the developmental age first; the chronological age alone can never make or exclude the diagnosis.

37.3 Criterion D: the exclusion with a deliberate carve-out

This is the cleverest criterion in the set, and the one most worth a mark. Criterion D states that the soiling must not be attributable to the physiological effect of a substance such as a laxative, or to another medical condition except through a mechanism that involves constipation. The exclusion clause is doing something unusual. Ordinarily a medical cause for a symptom rules a psychiatric label out. Here the manual carves an explicit exception: a medical condition is compatible with the diagnosis when, and only when, it produces the soiling by way of **constipation**. So a child with a low-fibre diet, or hypothyroidism, or coeliac disease, who

becomes constipated and then soils, still has encopresis, because constipation is the accepted final common pathway. By contrast, faecal incontinence arising through a mechanism that is not constipation - the chronic diarrhoea of a gut disease, or the neurogenic bowel of spina bifida, or an anal stenosis that leaks - does not warrant the diagnosis. The clause is not a loophole but the manual recognising that constipation-driven overflow is the disorder's own machinery, and that soiling produced by a different mechanism is a different problem wearing the same outward sign.

37.4 The two subtypes: retentive and non-retentive

The single most useful discrimination in the topic is between the constipated child and the unconstipated one, because they have opposite mechanisms, opposite associations and opposite treatments. The classification recognises exactly two forms, distinguished by whether constipation and overflow are present. The **retentive** form, with constipation and overflow incontinence, is much the commoner; the majority of children older than four who soil have this subtype. Here the stool is retained, the rectum is loaded, and what escapes is liquid overflow. The **non-retentive** form, without constipation and without overflow, is the smaller group: the stools are of normal form and are passed, intermittently, in the wrong place, and this pattern is more often linked with an oppositional or conduct disturbance than with a loaded bowel. The distinction is not academic. A child passing formed stools in inappropriate places without any constipation will not be helped by laxatives, and the clinical attention rightly shifts toward the emotional and behavioural picture, whereas the retentive child needs the bowel cleared before anything behavioural can work.

FEATURE	RETENTIVE (WITH CONSTIPATION AND OVERFLOW)	NON-RETENTIVE (WITHOUT CONSTIPATION)
Relative frequency	The majority of soiling children over four	The smaller group
Stool that soils	Liquid overflow leaking past a retained mass	Stools of normal form, passed intermittently
Constipation and impaction	Present and central	Absent
Typical association	The retention-pain cycle	Oppositional defiant or conduct disturbance
First move in treatment	Clear the impaction, then keep the stool soft	Address the behavioural and emotional picture

The two subtypes of encopresis run on opposite mechanisms; whether the bowel is loaded decides both the associations and the first step of treatment.

37.5 Epidemiology

The numbers are modest, age-dependent and sex-skewed, and each of those three shapes fits the mechanism. The prevalence runs at **one to four per cent** of children in high-income countries, with figures of two to eight per cent reported in some Asian countries. The disorder is far commoner in the younger school-aged child than the older: it is above four per cent between ages four and six and falls to below two per cent between ages ten and twelve, tracking the natural resolution of childhood constipation as the child grows, eats a fuller diet and consolidates

a toileting routine. It is more common in boys than in girls among older children. The age curve is the fact worth carrying: because most cases resolve with growth, persistence into later childhood marks the minority in whom the retention cycle has entrenched and warrants more determined treatment.

37.6 Etiology: the retention-constipation-overflow cycle

Everything about the retentive subtype makes sense once the cycle is drawn. The core mechanism is a self-perpetuating loop of painful defecation and withholding. A painful stool leads the child to withhold, withholding produces constipation, the retained stool becomes impacted, and liquid faeces then overflow around the impaction as incontinence. Once begun, the loop feeds itself: the longer the mass sits, the larger and harder it grows, the more painful its eventual passage, and the stronger the child's learned avoidance of the toilet. This is why **stool withholding** is the pivot of the whole disorder, a rational avoidance of pain that has catastrophic downstream consequences. The constipation that starts the loop may arise on either of two tracks:

- psychological, when the child withholds out of anxiety about defecating, a frightening earlier experience of a painful or hard stool, or oppositional refusal of the toilet;
- physiological, when the stool is hard and difficult to begin with, through ineffectual straining, a paradoxical contraction of the sphincter when the child bears down, a low-fibre and low-fluid diet, or an underlying condition such as hypothyroidism or coeliac disease.

An **anal fissure** closes the loop especially tightly, making the next stool acutely painful and so driving harder withholding still. Whichever track starts it, the destination is the same loaded rectum, and it is the loaded rectum, not the child's will, that produces the soiling.

37.7 Assessment: confirming the impaction

The assessment is short, physical and decisive, because it answers the one question that sorts the subtypes: is the bowel loaded. A careful history establishes the pattern of soiling, the stool form, the presence of pain or withholding behaviour, and the dietary and psychosocial context, and it screens for the red flags that would point away from simple constipation. The physical step that settles the subtype is the demonstration of retained stool: a **digital rectal examination** palpating a loaded rectum, or where that is not feasible or is equivocal, an abdominal radiograph showing faecal loading, confirms the impaction that defines the retentive form. This is not a formality: it converts a vague complaint of soiling into a mechanical diagnosis with an obvious first move, and it lets the clinician show the family that the problem is a full bowel and not a naughty child. The broader psychiatric and developmental workup, where the picture calls for it, follows the framework of the Child psychiatry: assessment, treatment, services and protection notes.

37.8 Management: clear, keep soft, retrain, de-shame

The treatment of the retentive form is a staged programme, and the order of the stages is the examinable core. The sequence is to first clear the retained stool by **disimpaction**, then to hold the bowel empty and the stool soft with **maintenance osmotic laxatives**, and to run alongside

these a **scheduled toileting programme** with dietary fibre, adequate fluid, and family education that demystifies and de-shames the problem. The order is not cosmetic. Disimpaction comes first because maintenance laxatives poured onto an impacted rectum simply add to the overflow; the mass must be gone before anything else can hold. Maintenance is then sustained deliberately over a long period, because the stretched, insensitive rectum needs an extended run of soft, easy, regular stools to recover its tone and sensation, and stopping the moment the soiling clears is the commonest route back to a loaded bowel. The behavioural programme, a regular unhurried sit on the toilet after meals to exploit the gastrocolic reflex, rebuilds the toileting habit the withholding destroyed. The family education carries as much weight as the drugs: a household managing the soiling as misbehaviour has to be brought round to seeing it as a bowel that overflowed, or the punitive dynamic will undo the regimen. This is behavioural-plus-laxative management, and it stands apart from the drug treatment of the bladder disorder taught elsewhere in this chapter, whose agents and doses do not belong here.

MNEMONIC

Clear, Keep, Sit, Teach

Clear the impaction by disimpaction; **Keep** the stool soft with sustained maintenance laxatives; **Sit** the child on a scheduled post-meal toileting routine with fibre and fluid; **Teach** the family that the soiling is overflow from a loaded bowel, not defiance. The order is not interchangeable: keeping, sitting and teaching all fail on a rectum that has not first been cleared.

PITFALL

The relapse trap is stopping the maintenance laxative too early. Soiling often clears within days of disimpaction and a few soft stools, and the natural instinct of family and clinician alike is to stop the medicine now that the child is clean. But the rectum is still stretched and under-sensing, and a bowel allowed to load again reproduces the whole cycle within weeks. Maintenance is continued well beyond symptom resolution and withdrawn slowly, not at the first clean week.

37.9 ICD-11, differentials and the examination traps

The two classifications agree, and the differentials are decided by mechanism rather than by the appearance of the soiling. The ICD-11 essential features mirror the manual, coding the disorder as 6C01 and setting the same approximate age-four developmental threshold. The differentials that earn marks all turn on the carve-out in Criterion D: soiling from chronic diarrhoea, from the neurogenic bowel of spina bifida, or from an anal stenosis is faecal incontinence, not encopresis, because the mechanism is not constipation. Within the diagnosis, the retentive and non-retentive forms are themselves a differential, resolved by whether the bowel is loaded. Two errors recur under examination pressure.

TRAP **Candidates read "except through a mechanism involving constipation" backwards.** The instinct is that any medical cause excludes the diagnosis, so a constipated child with hypothyroidism or coeliac disease gets marked as not having encopresis. The criterion says the opposite: a medical condition is compatible with encopresis precisely when it works through constipation. The exclusion removes only the non-constipation mechanisms, chronic diarrhoea and structural or neurogenic incontinence among them.

GOOD TO REMEMBER

When a school-aged child presents with what the family calls diarrhoea in the pants, think overflow before you think gastroenteritis. Frequent small leaks of foul liquid stool in an otherwise well child, especially with a history of hard or painful stools and toilet avoidance, is the retentive form declaring itself, and the abdomen or the rectal examination will usually find the loaded bowel that explains it. Treating that as an infective diarrhoea, or worse with a constipating agent, deepens the impaction it should be relieving.

Carry into the exam: encopresis is repeated faecal soiling from a developmental age of at least four years, at least monthly for three months, most often the involuntary overflow of a retentive, constipated bowel, managed by disimpaction, then sustained maintenance laxatives, a scheduled toileting routine and family education.

IN INDIA

Because services here classify under ICD, the operative label in case files is the entity coded 6C01, worked from its clinical descriptions. The disorder is genuinely common: prevalence figures in the region of two to eight per cent have been reported in some Asian countries, and low-fibre, low-fluid diets, cramped or shared and unhygienic toilets that a young child dreads, and the frank shame and punishment that soiling attracts in many households all feed the withholding that starts the cycle. Osmotic laxatives for disimpaction and maintenance are widely available and inexpensive, so the mechanical part of treatment is achievable; the harder work is the family education that reframes a shamed, punished child as a child with a loaded bowel, and it is that reframing that decides whether the routine holds.

1-4%	Age 4	≥1/month	3 months
PREVALENCE IN HIGH-INCOME COUNTRIES	MINIMUM CHRONOLOGICAL OR DEVELOPMENTAL AGE	SOILING EVENTS, THE FREQUENCY FLOOR	MINIMUM DURATION

38 · Pica

A child who eats what is not food, and keeps doing it. **Pica** is the persistent eating of **nonnutritive, nonfood substances** continued for **at least one month**. The substances vary with the child's age and with whatever is at hand: paper, soap, cloth, hair, string, chalk, paint, soil, clay, starch, ice, charcoal, pebbles. The defining oddity is that the child is not turning away from food. There is typically no aversion to nourishing food in general; the ingestion of nonfood matter sits alongside an otherwise ordinary appetite, which is exactly what marks pica out from

the disorders in which a child eats too little. Because the behaviour looks trivial to a lay eye and is easy to hide, the diagnosis rests on a clinician thinking to ask, and on separating a genuine disorder from a great deal of developmentally normal or culturally sanctioned mouthing and eating.

The marks here are discriminative and safety-driven. An examiner uses pica to test three things: whether a candidate can apply the developmental and cultural qualifiers that keep the diagnosis from swallowing normal behaviour, whether they know the company pica keeps, and whether they remember that this is a behaviour with hard medical consequences and not merely a curiosity. This topic owns pica in full: its criteria, the age floor, its substances and complications, its comorbidity, its differential and its management. The neighbouring feeding disorders of childhood are named here only where the reasoning needs them and are taught in their own right elsewhere in this chapter.

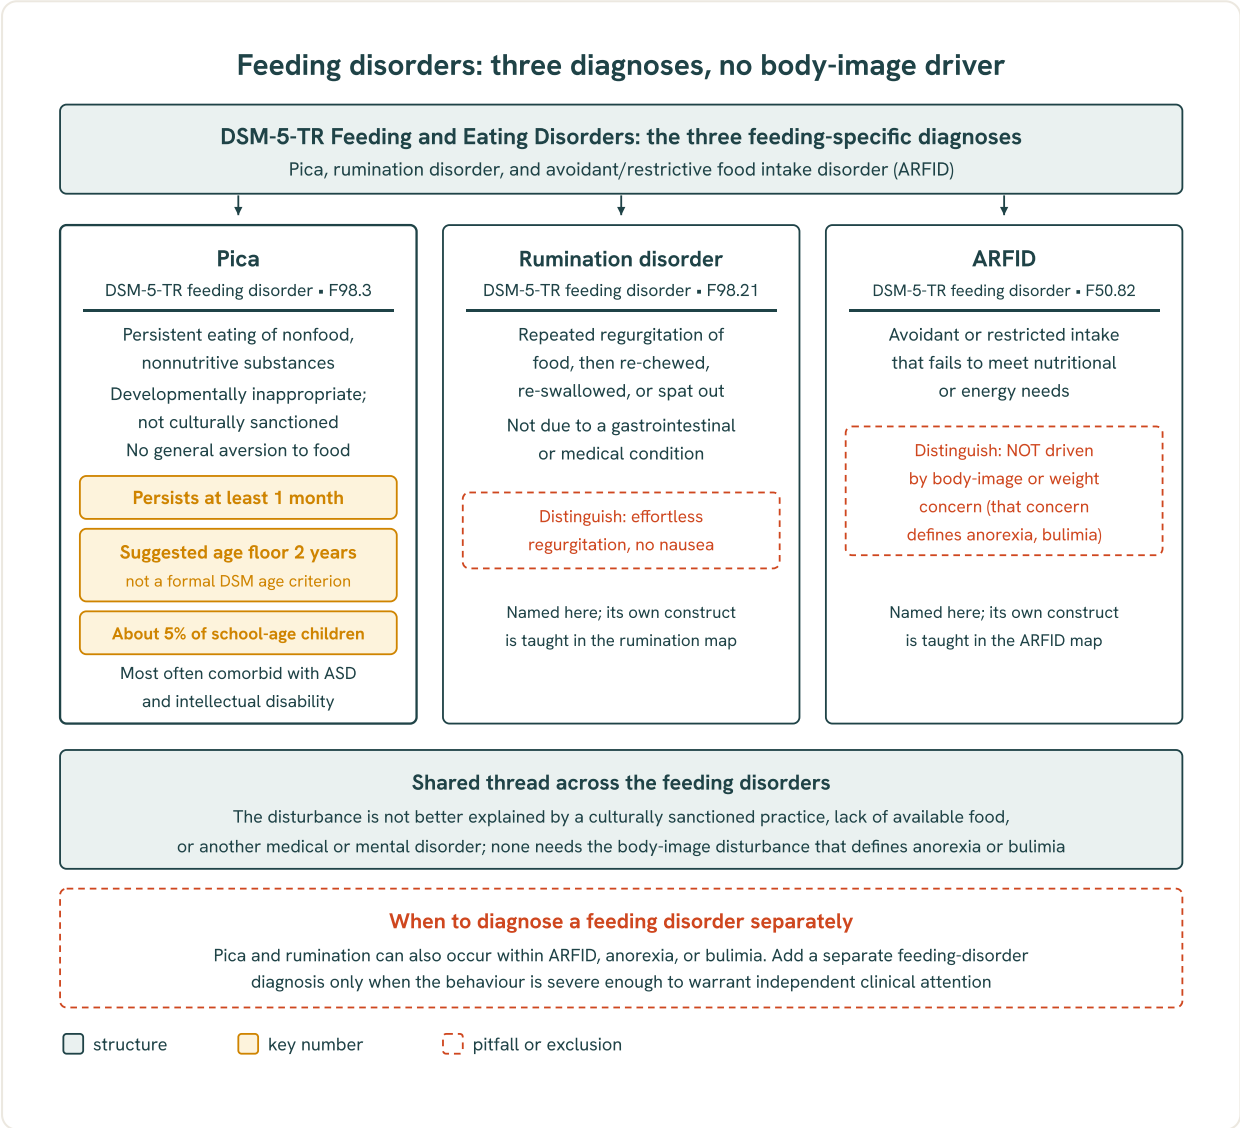

Fig 23.29. Feeding disorders map: pica taught in full, with rumination disorder and ARFID named as the sibling feeding diagnoses that share the absence of a body-image driver.

38.1 The essential feature: nonfood eating, persistent, with appetite intact

The behaviour is an addition to eating, not a subtraction from it. The core requirement is the repeated ingestion of substances that carry no nutritional purpose, sustained rather than a single curious episode, and present for a defined minimum period rather than a passing phase. What a candidate must hold is the qualitative shape of the behaviour. First, it is persistent: an isolated instance of a toddler swallowing a button is not the disorder. Second, the substances are genuinely nonnutritive, so the deliberate eating of low-calorie diet products, which do have some nutritional content, does not qualify. Third, and most usefully in the clinic, the child usually eats food normally as well; pica coexists with an ordinary appetite rather than replacing it. That last point is the fastest way to separate pica at the bedside from a restrictive feeding problem, where the whole difficulty is a narrowed or diminished intake of food itself.

38.2 The qualifiers that keep the diagnosis honest: development, culture and the age floor

Three gates stand between the behaviour and the diagnosis. Not every child who eats nonfood matter has a disorder, and the criteria are built to say so. The eating must be **developmentally inappropriate**, which excludes the universal hand-to-mouth exploration of infancy, when putting objects in the mouth and occasionally swallowing them is a normal stage rather than pathology. It must not be a **culturally supported or socially normative practice**, because in some communities the eating of particular earths or clays is a sanctioned custom and not a sign of illness. And where the eating occurs in the context of another disorder such as autism spectrum disorder, intellectual disability or schizophrenia, a separate diagnosis of pica is made only when the behaviour is severe enough to warrant clinical attention in its own right. To operationalise the developmental gate, a minimum age of **two years** is suggested before the diagnosis is entertained, so that the normal mouthing of the very young is not relabelled as a disorder.

- persistent nonfood eating for the required minimum period, with food eaten normally;
- developmentally inappropriate for the child's age and stage;
- not a culturally sanctioned or socially normative practice;
- if within another disorder, severe enough to deserve independent clinical attention.

RULE **Pica is nonfood eating that is developmentally inappropriate, not culturally sanctioned, and old enough to count.** The behaviour alone is never sufficient. It becomes a diagnosis only once it has cleared the developmental gate, the cultural gate and, where it rides on another disorder, the severity gate. Strip any one of these away and the criteria would capture the exploring infant and the observant clinician alike.

38.3 The substances, and why they are dangerous

What is eaten decides the harm. The preferred substances cluster into recognisable patterns that have acquired their own descriptive names, of which the eating of earth or soil, or **geophagia**, is the classic, alongside the eating of ice and of raw starch. The choice is shaped by age and by availability, which is why the substance changes as the child grows and why environment matters so much. The clinical weight of pica lies not in the strangeness of the

behaviour but in its consequences. Ingested nonfood matter can cause gastrointestinal obstruction, perforation and the formation of concretions in the gut; contaminated soil carries a risk of parasitic infestation; and the swallowing of paint or dust in older housing is a recognised route to lead exposure and its neurotoxicity. These are the reasons an examiner treats pica as a medical problem wearing a behavioural coat, and the reasons the assessment cannot stop at naming the behaviour.

38.4 Comorbidity: the developmental company pica keeps

Where you find pica, look for a developmental disorder. Pica is most commonly seen alongside **autism spectrum disorder** and **intellectual disability**, and the risk tends to rise with the severity of the intellectual impairment. To a lesser degree it is associated with schizophrenia and with obsessive-compulsive disorder. There is a further, characteristic pairing worth carrying into the exam: where a child is pulling out and then eating their own hair, or picking at and ingesting their skin, pica may accompany trichotillomania and excoriation disorder, and the swallowed hair can itself produce a gastric mass. Both autism spectrum disorder and intellectual disability are developed in their own right in the Intellectual disability and autism spectrum disorder notes; here they matter as the settings that should raise suspicion of pica and, conversely, as conditions the clinician must weigh when a child presents eating nonfood substances. The general point is that pica is rarely a lone finding in an otherwise typically developing older child, and its appearance should prompt a look at the wider developmental picture.

38.5 Differential diagnosis

The task is to separate pica from the behaviours it resembles. The accompanying figure maps the feeding and eating disorders of childhood and places pica alongside its neighbours, each of which is separated from it by a single clear feature. The commonest confusions are with normal infant mouthing, with the two other feeding disorders of childhood, and with the hair-and-skin conditions in which ingestion is secondary.

CONDITION TO DISTINGUISH	WHAT SEPARATES IT FROM PICA
Developmentally normal mouthing of infancy	Ingestion follows the ordinary oral exploration of the very young; the suggested age floor of two years and the developmental-appropriateness gate exclude it
Rumination disorder	Repeated regurgitation and re-chewing of already-swallowed food, not the eating of nonfood matter; a disorder of what comes back up rather than what goes down
Avoidant/restrictive food intake disorder	Avoidance or restriction of food leading to inadequate intake, with no ingestion of nonfood substances; the opposite failure of the feeding repertoire, and taught separately in this chapter
Trichotillomania or excoriation with ingestion	The hair-pulling or skin-picking is primary; pica is added only when the eating of the hair or skin is itself a clinical focus
Nonfood eating within another disorder	A separate pica diagnosis is warranted only if the behaviour is severe enough to merit independent attention, not whenever it appears in autism, intellectual disability or schizophrenia

The behaviours pica is most often confused with; each is separated by a single feature rather than by appearance, which is why the qualifiers and the age floor carry the differential.

38.6 Assessment and management

Investigate the body, then modify the behaviour. Because the danger of pica is physical, the assessment is as much medical as psychiatric. A clinician evaluates for the complications the ingested material can cause and for the deficiency states, iron and zinc among them, that are associated with the behaviour, screens for lead exposure where the history or housing suggests it, and looks for gastrointestinal obstruction or a concretion where symptoms point that way. Correcting an identified nutritional deficiency can itself reduce the behaviour, which is why the workup is not optional. Beyond the medical arm, management rests on behavioural strategies and on securing the environment: removing access to the preferred substances, close supervision, and where the child has a developmental disorder, structured behavioural interventions to reduce the ingestion and to build safer alternatives. In many young children the behaviour remits with maturation and with attention to the setting, but the coexisting developmental or nutritional problem often needs its own continuing care. There is no specific medication that treats pica as such; where drugs are used they target a comorbid condition, and any pharmacological choice should be confirmed against a pharmacology source rather than assumed.

Carry this into the exam: persistent eating of nonnutritive, nonfood substances for a month or more, developmentally inappropriate, not culturally sanctioned, in a child of at least two years, most often alongside autism spectrum disorder or intellectual disability.

TRAP **Diagnosing pica in the mouthing infant.** The classic examination error is to label the very young child who explores by mouth and swallows the occasional object as having pica. The suggested minimum age of two years and the requirement that the eating be developmentally inappropriate exist precisely for this child: below that stage the behaviour is a normal part of development, not a disorder.

PITFALL

The commonest clinical failure is to treat pica as a purely behavioural quirk and to skip the medical workup. A child eating soil, paint flakes or hair can arrive with iron-deficiency anaemia, lead exposure, worm infestation, a gut obstruction or a swallowed-hair mass, and none of these is found unless it is looked for. Naming the behaviour and stopping there misses the very harms that make pica worth diagnosing.

GOOD TO REMEMBER

When a child presents with pica, two reflexes change what you do that day: check iron status, because deficiency both drives and is driven by the behaviour and correcting it may resolve it; and take an exposure and access history, because what the child can reach and what the housing contains determine both the medical risk and the first line of management, which is simply removing access.

IN INDIA

Two realities shape pica in Indian practice. Geophagia, the eating of earth or clay, is in some communities a sanctioned custom, at times during pregnancy, and the cultural-exclusion criterion is written for exactly this: a socially normative practice is not a disorder, and the clinician must establish the community norm before reaching for the diagnosis. At the same time, the same soil-eating carries a real burden of iron-deficiency anaemia and of soil-transmitted helminth infestation, so a behaviour that may be culturally ordinary can still demand a medical response. Holding both truths at once, respecting the custom while treating the anaemia and deworming where indicated, is the practical skill this topic tests.

1 month	2 years	ASD, ID
MINIMUM DURATION OF THE BEHAVIOUR	SUGGESTED MINIMUM AGE FOR DIAGNOSIS	COMMONEST DEVELOPMENTAL COMORBIDITIES

39 · Rumination disorder

The child is not sick, and the food comes back up anyway. **Rumination disorder** is the repeated, effortless bringing back up of food that has already been swallowed, so that it can be re-chewed and then re-swallowed or spat out. The defining quality is that it happens without the child appearing ill: there is no nausea beforehand, no retching, no visible disgust, and often no obvious distress at all. Partially digested food simply reappears in the mouth minutes after a meal, is worked over again, and is either swallowed back down or ejected. To an observer who does not know the condition it can look like an odd habit, a digestive complaint, or a mild illness; to the clinician who does, that very absence of the machinery of ordinary vomiting is the diagnosis.

The marks here are about discrimination and about not medicalising the wrong thing. An examiner uses this topic to test whether a candidate can separate an effortless, behaviourally maintained regurgitation from true vomiting, from acid reflux, and from the several structural and neurological conditions that also send food back up. This topic owns rumination disorder in full: its core criterion, its phenomenology, its frequency and duration requirements, the medical and psychiatric conditions it must be told apart from, and its reach across the lifespan. The neighbouring feeding disorders are developed in their own right elsewhere in this chapter and are named here only where the reasoning needs the contrast.

39.1 The essential feature: effortless regurgitation and re-chewing

The whole diagnosis is a repeated, effortless return of already-swallowed food. The core requirement is a repeated **regurgitation** of food, in which previously swallowed, partially digested material is brought back up into the mouth and is then re-chewed, re-swallowed, or spat out. The word regurgitation is doing precise work: this is not the forceful expulsion of vomiting driven by a reflex arc, but a gentle, almost passive reappearance of a bolus that the child then processes again. Because the child produced the swallow in the first place and can carry the food back down afterwards, the act sits closer to a self-generated behaviour than to a symptom happening to the child, and it is this behavioural quality, more than any single feature, that the rest of the topic hangs on.

RULE **Effortless regurgitation without nausea, retching or disgust is rumination; forceful, distressed expulsion is not.** The presence of premonitory nausea, retching, autonomic distress or evident disgust points away from rumination and towards true vomiting or an organic cause. Rumination is quiet, repetitive and post-prandial, and the child frequently seems untroubled by it, which is exactly why it is missed.

39.2 The phenomenology that separates it from vomiting

Read the seconds after the meal, not the vomit bowl. The regurgitated material is characteristically food that was swallowed only minutes earlier and is still recognisable and only partially digested, brought up without the sour, fully acidified quality of gastric vomit and without the preceding wave of nausea. The episode typically begins soon after eating and can recur through the post-prandial period. Many affected children can be observed to initiate the return of food, for instance by particular movements of the tongue, jaw or abdominal wall or by posturing, and the whole sequence tends to be repetitive and stereotyped across meals. None of this resembles the single, effortful, distressing event of true vomiting. The clinical skill the examiner is probing is the willingness to watch a meal and the period straight after it, rather than to reach for an antiemetic or an endoscopy on the assumption that returning food must be a gut disease.

- the material is recently swallowed and only partially digested, not fully acidified gastric content;
- there is no premonitory nausea and no retching;
- the episodes are post-prandial, repetitive and often self-initiated;

- the child commonly appears indifferent rather than distressed.

39.3 How often and for how long: the frequency and duration thresholds

Occasional posseting is not the disorder; a sustained, frequent pattern is. For the diagnosis the regurgitation must have been present for **at least one month**, and it should be a frequent behaviour rather than a rare event, occurring on the order of **several times a week** and often daily. These thresholds do two things. The duration floor screens out the transient regurgitation that many infants show and grow out of, reserving the label for a pattern that has proven itself durable. The frequency expectation stops a very occasional episode from being over-read as a disorder. Together they mark rumination as an established, repeating behaviour, which matters because it is the persistence and the repetition, not the mere fact of food returning once, that carry the nutritional and developmental risk.

39.4 Excluding the medical mimics

Rumination is a diagnosis of a behaviour, made only once organic causes are excluded. The regurgitation must not be attributable to an associated gastrointestinal or other medical condition, and this exclusion is the heart of the differential. The obvious mimic is **gastroesophageal reflux**, in which acidic stomach content passes back up the oesophagus; the returning material there is sour and refluxed rather than re-chewed, and the mechanism is a failure of the lower oesophageal sphincter, not a learned behaviour. Structural obstruction such as **pyloric stenosis** produces true, often forceful vomiting from a mechanical block to gastric emptying, and delayed emptying from **gastroparesis** or an anatomical hiatal hernia can each mimic the picture. A particular neurological trap is **Sandifer syndrome**, in which reflux drives paroxysmal dystonic posturing of the head and trunk that can be mistaken for a movement disorder or for the posturing of rumination itself. Only when these have been considered and do not account for the picture is the behavioural diagnosis made.

CONDITION	WHAT SEPARATES IT FROM RUMINATION
Gastroesophageal reflux	Sour, acidified content refluxed passively through an incompetent sphincter; not re-chewed and re-swallowed, and typically with acid symptoms
Pyloric stenosis	Mechanical gastric outlet obstruction producing true, often projectile vomiting rather than effortless return of chewable food
Gastroparesis / hiatal hernia	Delayed emptying or an anatomical defect causing regurgitation or vomiting on a structural, not behavioural, basis
Sandifer syndrome	Reflux-associated dystonic posturing of the neck and trunk, a neurological mimic that must not be read as the disorder

The organic conditions rumination must be told apart from; each is separated by its mechanism rather than by the mere appearance of returning food, which is why the medical exclusion is done before the behavioural label is applied.

TRAP **Calling refluxed acid rumination, or calling rumination reflux.** The classic examination error is to collapse the two. Reflux brings up sour gastric content through a passive mechanism and is not re-chewed; rumination brings up recently swallowed, still-chewable food that the child works over again, with no nausea and no acid burn. Mistaking one for the other leads either to fruitless anti-reflux treatment or to a missed behavioural diagnosis.

39.5 The eating-disorder exclusion and the additional-attention rule

Two further exclusions keep rumination a distinct entity. The behaviour must not occur exclusively during the course of an eating disorder. If the regurgitation happens only within anorexia nervosa, bulimia nervosa, binge-eating disorder or **avoidant restrictive food intake disorder**, then that condition, not rumination, is the diagnosis; those disorders are taught in their own right, with ARFID developed elsewhere in this chapter and the classical eating disorders in the Eating and sleep-wake disorders notes. The final rule addresses the common situation in which rumination arises alongside another mental disorder, most often an intellectual or neurodevelopmental one: here the regurgitation is diagnosed as an additional condition only when it is severe enough to warrant independent clinical attention in its own right, rather than being folded into the background disorder. This prevents both the over-diagnosis of a minor behaviour and the neglect of a genuinely dangerous one.

39.6 Across the lifespan, and the association with intellectual disability

It is not only an infant's problem. Although rumination is classically described in infancy, it can be diagnosed across the lifespan, in older children, adolescents and adults, and it is seen with particular frequency in people with **intellectual disability**. In infants the behaviour is often understood as self-stimulating and self-soothing, emerging where the ordinary regulation and stimulation provided through feeding interactions is lacking; in individuals with significant intellectual disability it can become an entrenched, self-reinforcing habit. The practical importance of remembering the lifespan reach is that a non-verbal adolescent or adult with intellectual disability who repeatedly brings food back up is easily assumed to have a gastrointestinal problem, and the behavioural nature of the regurgitation is overlooked precisely in the group most likely to have it.

PITFALL

The commonest clinical failure is to subject a ruminating child to an escalating series of invasive gastrointestinal investigations and empirical anti-reflux treatments while never watching a meal. Because the returning food looks like a gut symptom, the workup runs down the organic track for months, when a period of direct observation after eating would have shown the effortless, self-initiated, re-chewed regurgitation and made the diagnosis at the bedside.

IN INDIA

Two realities shape recognition here. Rumination is most often encountered in children and adults with intellectual disability, many of whom are in family or institutional care with limited access to specialist feeding assessment, so the behaviour is frequently attributed to physical illness and worked up repeatedly before anyone names it. And because most services diagnose under ICD, the clinician should hold the same behavioural picture in mind under that framework and resist the pull towards a purely gastroenterological formulation, particularly in a non-verbal patient who cannot report the absence of nausea themselves.

39.7 Why it matters and the principles of management

Left unrecognised it costs weight, nutrition and, sometimes, life. The repeated loss of ingested food can produce weight loss, failure to thrive or malnutrition, dental erosion from the returned material, halitosis and social rejection, and in the most severe cases the nutritional compromise is dangerous. Because the disorder is behavioural, management is directed at the behaviour and its context rather than at the gut. The mainstay in infants and in those with intellectual disability is a behavioural and interactional approach: enriching the feeding relationship and the child's stimulation, and, where a specific technique is used, teaching an action incompatible with regurgitation such as diaphragmatic breathing after meals. The details of specific behavioural protocols and of any pharmacological adjunct lie outside what this topic establishes and should be confirmed against a dedicated source. What the candidate must carry is the logic: identify the effortless, re-chewed, post-prandial regurgitation, exclude the organic mimics, and treat it as a behaviour, not as a disease of the stomach.

GOOD TO REMEMBER

The single most useful investigation is often free: observe the patient during and for the half hour after a meal. Watching the recently swallowed food return effortlessly, be re-chewed and re-swallowed, with no nausea and no retching, settles the diagnosis more cheaply and more certainly than any imaging, and it also reframes the family's understanding of the problem from an illness to be cured to a behaviour to be reshaped.

Carry this into the exam: effortless, post-prandial regurgitation of recently swallowed food that is re-chewed, without nausea or retching, for at least a month and not explained by reflux or another medical condition, is rumination disorder.

40 · Avoidant restrictive food intake disorder (ARFID)

A child can starve without ever having a thought about weight or shape, and that is the whole point of this diagnosis. **Avoidant/restrictive food intake disorder** describes a persistent disturbance of eating or feeding in which the intake of food, in amount or in variety or in both, is

so restricted that the body or the life suffers for it, yet the restriction is driven by something other than a wish to be thin. The child eats too little, or too narrow a range, because food does not interest them, or because its look, smell or texture repels them, or because they are frightened of what eating might do to them. What is absent is any concern about becoming fat and any distortion in how their weight or shape is experienced. Holding those two facts together, real physical or functional harm on one side and a complete absence of body-image pathology on the other, is the entire topic.

The marks here are almost entirely discriminative. An examiner is testing whether a candidate can recognise a restrictive eating disorder that is not an eating disorder in the classical, weight-and-shape sense, and can therefore avoid the reflex of calling every underweight child who refuses food an anorexia case. This topic owns the criteria of the disorder and, above all, the boundary that separates it from the weight-driven eating disorders; anorexia nervosa and bulimia nervosa themselves belong to the Eating and sleep-wake disorders notes and are only named and cross-referred here, never taught.

40.1 Criterion A: a feeding disturbance that must cause real harm

The eating disturbance is only a disorder when it produces a consequence. The diagnosis is not made on fussy eating alone. There must be an eating or feeding disturbance that fails to meet the child's nutritional or energy needs, and that failure must show itself through at least one of **four** possible consequences. The restriction may cause significant weight loss, or in a growing child a failure to gain expected weight and **faltering growth**; it may produce a significant nutritional deficiency; it may force a dependence on enteral tube feeding or on oral nutritional supplements to keep the child fed; or it may cause a marked interference with psychosocial functioning, so that mealtimes, school trips, family meals and social life are disrupted by the eating problem. Any one of these clears the bar. The last of them matters more than candidates expect, because it means a child of entirely normal weight can still qualify: the harm can be to the life rather than to the body mass.

- significant weight loss, or faltering growth and failure to gain expected weight in a child;
- a significant nutritional deficiency;
- dependence on enteral feeding or oral nutritional supplements to meet needs;
- marked interference with psychosocial functioning.

PITFALL

Waiting for the child to be underweight before considering the diagnosis. Because one of the qualifying consequences is functional and social rather than nutritional, a normal-weight child whose extreme selectivity has made every meal a battle and every outing impossible can meet Criterion A in full. Anchoring on the scale alone will make the clinician miss exactly these children, who are often the ones causing the most family distress.

40.2 The three drivers of the restriction

Why the child is not eating tells you which ARFID you are looking at. The restriction is understood through **three** characteristic drivers, and a given child may sit on one or on more than one of them. The first is an apparent **lack of interest** in eating or in food, a low drive to eat in which the child simply does not seem hungry, forgets to eat, or tires of a meal after a few mouthfuls. The second is avoidance based on the sensory characteristics of food, the intense, selective refusal of foods by texture, smell, colour, temperature or appearance that produces the classic child who will eat only a handful of beige, dry, predictable items. The third is a concern about the aversive consequences of eating, a conditioned fear that follows a frightening experience such as choking, a traumatic gastrointestinal procedure or an episode of vomiting, and that then generalises into avoidance of the foods or the act of eating that the child associates with it, sometimes called functional dysphagia.

DRIVER	WHAT THE CHILD SHOWS	WHAT IT IS NOT
Apparent lack of interest in eating or food	Low appetite drive, early satiety, forgetting to eat, no pleasure in food	Not a wish to lose weight; the child is indifferent to food, not restricting it deliberately
Sensory-based avoidance	Refusal by texture, smell, colour or appearance; a narrow, fixed repertoire of accepted foods	Not calorie avoidance; the same food would be eaten if its sensory qualities were tolerable
Concern about aversive consequences	Fear of choking, vomiting or pain after a frightening event; avoidance of feared foods or of eating itself	Not fear of weight gain; the dread is of a bodily catastrophe while eating, not of fatness

The three drivers of avoidant and restrictive intake. Each explains the restriction by a mechanism that has nothing to do with weight or shape, which is what keeps the whole disorder distinct from the weight-driven eating disorders.

GOOD TO REMEMBER

The sensory-avoidant presentation overlaps heavily with autism spectrum presentations, where narrow, texture-bound eating is common. When you meet the child with an extremely restricted food repertoire, screen deliberately for the wider neurodevelopmental picture, and remember that the eating problem still needs its own nutritional and feeding-focused management rather than being written off as just part of the autism.

40.3 Criterion C: the absence of body-image disturbance is the whole diagnosis

ARFID is the restrictive eating disorder without the weight-and-shape motive. The single most important criterion is the one that draws the boundary with the classical eating disorders. The eating disturbance must not occur exclusively during the course of anorexia nervosa or bulimia nervosa, and there must be **no disturbance in the way the person's body weight or shape is experienced**. This is the crux. In anorexia and bulimia the restriction is powered by a fear of fatness and a distorted perception of the body; in ARFID it is powered by lack of interest, sensory aversion or fear of an aversive consequence, and the person has no drive for thinness and no distorted body image at all. Where genuine weight or shape concern is present and driving the restriction, the diagnosis is not ARFID. Anorexia nervosa and bulimia nervosa are developed in

their own right in **the Eating and sleep-wake disorders notes**; here they are the comparators against which ARFID is defined.

RULE **No weight or shape concern, no distorted body image: that absence is what makes it ARFID.** The restriction in ARFID is driven by disinterest, sensory aversion or fear of aversive consequences, never by a wish to be thin. The moment a distorted experience of body weight or shape is driving the eating, the clinician has left ARFID and is in the territory of anorexia or bulimia.

TRAP **Labelling every underweight, food-refusing child as anorexia nervosa.** The classic error is to reason from low weight and restricted intake straight to anorexia, without asking why the child is restricting. If there is no fear of weight gain and no body-image distortion, and the avoidance is sensory or a conditioned fear of choking or vomiting, the diagnosis is ARFID, and treating it as anorexia will target a motive the child does not have.

40.4 Criteria B and D, and where ARFID came from

Two exclusions keep the diagnosis honest. Criterion B requires that the disturbance is **not better explained by a lack of available food** or by a culturally sanctioned practice, so that a child who is undernourished because the family cannot afford food, or who eats little during a religious fast, is not captured. Criterion D requires that the eating disturbance is not attributable to a concurrent medical condition and is not better explained by another mental disorder; where an eating problem is fully accounted for by a physical illness or by another psychiatric condition, that condition is the diagnosis. ARFID is a positive entity, not a residual bin, and these two exclusions are what stop it swallowing every cause of low intake in childhood. Historically, the category was created to replace and extend the older DSM-IV feeding disorder of infancy or early childhood, carrying that clinical reality forward and widening it to older children, adolescents and adults, who were previously left without a home for a restrictive eating problem that was not anorexia.

40.5 Assessment and the company ARFID keeps

The assessment is built to answer one question before all others. Because the diagnosis turns on the motive for restriction and on the presence of harm, the assessment is directed at establishing both. The clinician documents the pattern and the range of foods eaten and refused, elicits which of the three drivers is operating, and actively probes for any weight or shape concern, since its presence or absence decides the diagnosis. In parallel the clinician establishes harm: the growth trajectory and any faltering, nutritional adequacy and specific deficiencies, any reliance on supplements or tube feeding, and the degree of psychosocial and family disruption. The differential is wide and must be worked through with care, because low intake in a child can arise from a medical cause of poor appetite or dysphagia, from a depressive disorder, from an anxiety or obsessive presentation, and, in the sensory-avoidant child, from an autism spectrum disorder whose restricted eating is part of a broader pattern. ARFID is diagnosed when the eating disturbance stands as a problem in its own right rather than being fully explained by one of these.

Carry this into the exam: restricted intake plus real harm, driven by disinterest, sensory aversion or fear of an aversive consequence, and with no fear of fatness and no distorted body image, is ARFID, not anorexia.

40.6 Principles of management

Feed the child, treat the driver, and do not import an eating-disorder model that does not fit. Management follows from the mechanism rather than from a single protocol. The first duty is the physical one: correcting undernutrition, restoring growth, replacing specific deficiencies and, where the child depends on tube feeding or supplements, working deliberately towards oral intake. Beyond that, the psychological work is matched to the driver. Sensory-based avoidance is approached with graded, patient exposure to new textures and foods and a widening of the repertoire, usually with close involvement of the family and often a feeding or occupational-therapy input. The conditioned fear of an aversive consequence is treated on an anxiety model, with graded exposure to the feared foods and to the act of eating, undoing the association that a choking or vomiting episode laid down. The child with a low drive to eat needs structure, appetite-supporting routines and attention to any contributing medical cause. Crucially, because there is no body-image pathology to address, the cognitive work aimed at weight and shape concern that anchors anorexia and bulimia treatment has no target here and should not be transplanted across; specific pharmacological agents and dosing lie outside what this topic establishes and should be confirmed against a pharmacology source.

IN INDIA

ARFID is under-recognised in Indian practice, partly because extreme faddiness is culturally read as ordinary childhood behaviour and met with coaxing or force-feeding rather than assessment. Two discriminations become especially live here. First, Criterion B does real work: in a setting where undernutrition from food insecurity is common, the clinician must establish that food was available and the child restricted it, not that the family could not provide it. Second, the very common paediatric complaint that "my child does not eat" hides a small number of genuine ARFID cases among a large majority of normal variation, so the useful clinical move is to ask specifically about harm, growth faltering, nutritional deficiency and the collapse of family and social life around meals, which is what separates the disorder from the ordinary fussy eater.

41 · Breath-holding spells and other transient childhood behavioural phenomena

A frightening event with a benign heart. Few things alarm a parent more than watching a toddler cry, stop breathing, change colour and go limp, and few things reassure a clinician more once the pattern is recognised for what it is. **Breath-holding spells** are involuntary, reflexive episodes in which a young child, provoked by a sudden emotional or physical stimulus, stops breathing in expiration long enough to lose colour, tone and consciousness, and then recovers

completely and spontaneously. The whole event is dramatic, stereotyped and self-terminating, and the single most important thing a candidate can say about it is that it is neither an act of will nor a form of epilepsy. The marks in this topic are earned by holding that reframe steady against the two intuitions that mislead everyone in the room, the parent who is sure the child is doing it deliberately, and the clinician who reaches for an anticonvulsant.

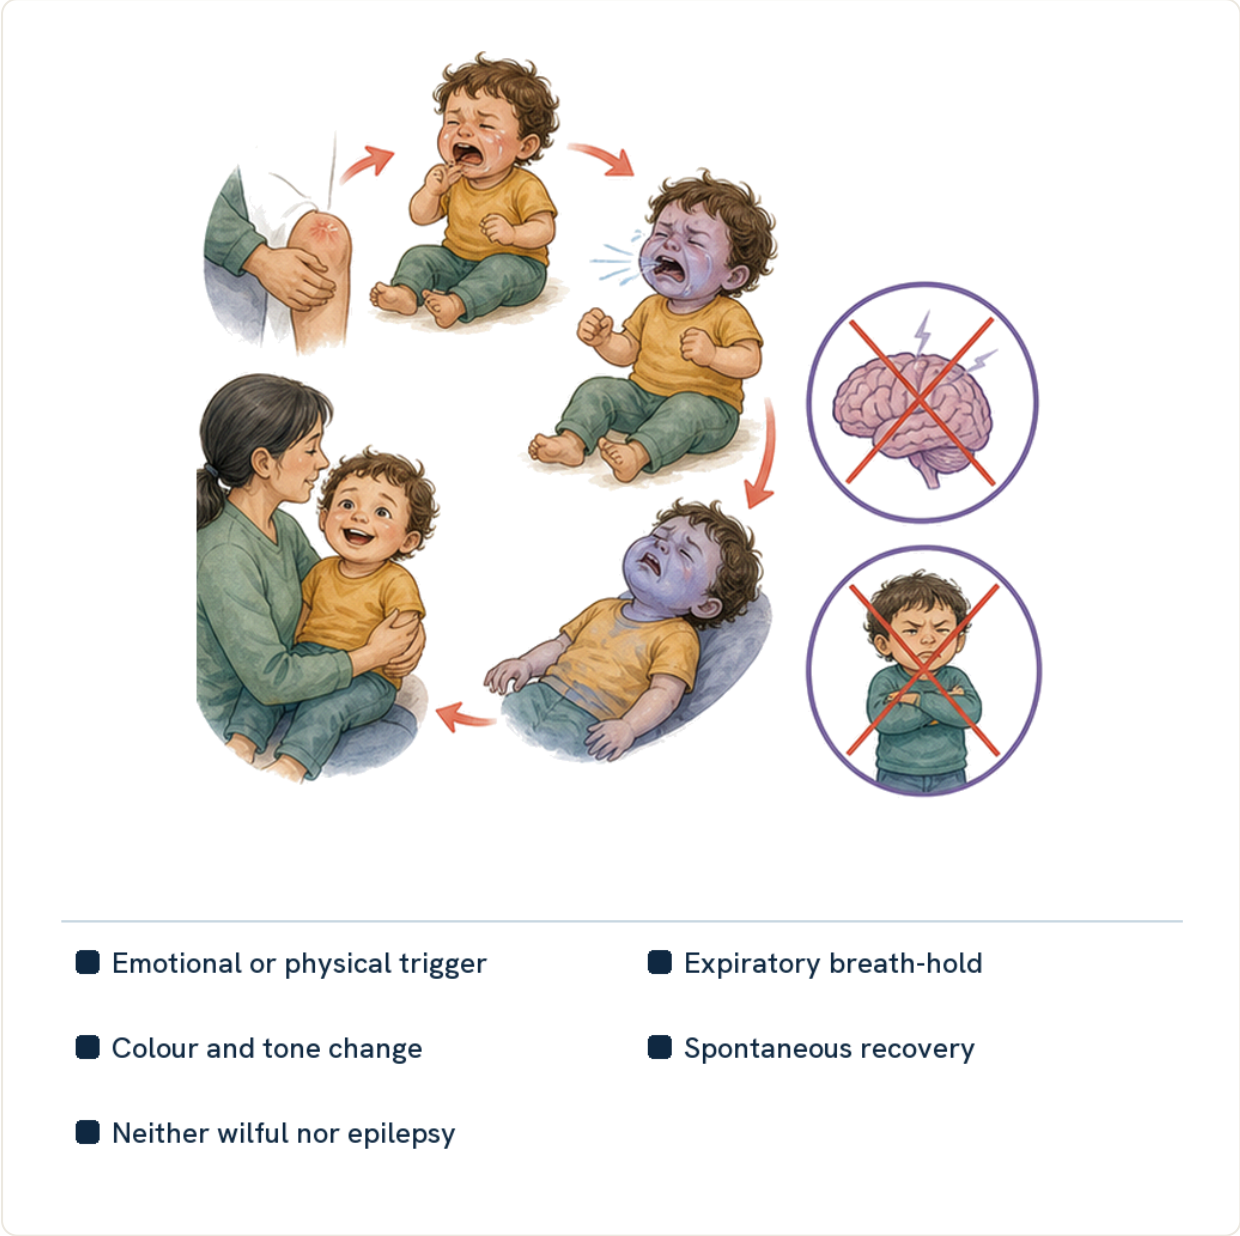

Fig 23.30 Breath-holding spells are involuntary reflex episodes after an emotional or physical trigger. Expiratory breath-holding may produce colour change, loss of tone and brief loss of consciousness, followed by complete spontaneous recovery.

The topic also carries the broader heading of the transient behavioural phenomena of early childhood, the ordinary, self-limiting habits and reflexes that occupy the wide territory between normal development and disorder. Breath-holding is the one that reaches the examination as a discrete named entity, so it is taught here in full; the others are named and placed, because their value is precisely that they do not need treating.

41.1 A reflex, not a willed act

The child does not decide to hold their breath. The name is a misnomer that has cost countless toddlers a spanking and countless parents a needless guilt. What looks like a defiant, deliberate withholding of breath is in fact an involuntary reflex arc triggered by a provoking stimulus, running to completion outside the child's control and ending on its own. This distinction is not pedantic. If the behaviour were voluntary, the correct response would be to refuse to reward it; because it is reflexive and benign, the correct response is calm handling and the removal of the fear that surrounds it. The spell always follows a provocation and never occurs in sleep, and the child has no memory of the loss of consciousness itself. Recovery is complete within a minute, with no drowsiness, no confusion and no lasting deficit, which is exactly the profile a candidate must be able to recite to separate this from the seizure it imitates.

RULE **A breath-holding spell is an involuntary, benign, self-limiting reflex, not wilful defiance and not epilepsy.** Every management decision follows from this one sentence. There is no neurological damage from the spells themselves, the child cannot be disciplined out of them, and anticonvulsants have no place. The clinician's work is to recognise the pattern, exclude the small number of genuine mimics, and hand the family confident reassurance in place of dread.

41.2 Epidemiology and natural history

Common, early and outgrown. Breath-holding spells affect between **0.1% and 4.6%** of otherwise healthy young children, so they are common enough that a paediatric or child-psychiatry clinic will see them regularly, and they cluster in a narrow developmental window. Onset is usually between **6 and 18 months** of age, the period in which the autonomic and brainstem systems that drive the reflex are still maturing, and the great majority of children have stopped having spells by **5 years** of age. That trajectory, appearing in infancy and disappearing spontaneously by school age, is itself a reassuring feature and part of the natural history a candidate is expected to know. The examiner is not testing whether the child will grow out of it, because the answer is almost always yes; the examiner is testing whether the clinician can promise that outcome without first excluding the conditions that masquerade as it.

GOOD TO REMEMBER

The natural history is the therapy. Once the diagnosis is secure, the most powerful intervention available is telling the family, plainly and confidently, that the spells are harmless, that the child is not brain-damaged and is not being manipulative, and that the episodes will fade on their own within the first few years of life. Anxious, over-protective handling and repeated capitulation to the child prolong the pattern; matter-of-fact calm shortens it.

41.3 The two types: cyanotic and pallid

Two triggers, two colours, one benign end. Breath-holding spells come in two forms distinguished by their provocation and the colour the child turns. The **cyanotic type** is the more common. It is usually precipitated by anger or frustration: the child emits a short, loud cry, then involuntarily holds the breath in forced expiration, becomes cyanosed, goes rigid or limp with a transient loss of consciousness, and then takes a long inspiration and recovers. The **pallid type** is

more often precipitated by pain or fear, such as a minor bump to the head or a sudden fright; here the crying may be minimal or silent, the apnoeic period is briefer, and the child develops pallor rather than cyanosis before losing consciousness. In both types the entire episode lasts approximately **10 to 60 seconds** and ends in full recovery.

FEATURE	CYANOTIC SPELL	PALLID SPELL
Relative frequency	The commoner of the two	The less common
Usual provocation	Anger or frustration	Pain or fear (a bump, a fright)
The cry	A short, loud cry precedes the apnoea	Crying may be minimal or silent
Colour change	Cyanosis, from breath held in forced expiration	Pallor, before loss of consciousness
Proposed mechanism	Respiratory, with autonomic dysregulation	Vagally-mediated cardiac inhibition, with reflex asystole or bradycardia
Course of the episode	Rigidity or limpness, brief loss of consciousness, then a long inspiration and full recovery	A briefer apnoeic phase, otherwise proceeds and recovers as the cyanotic spell

The two forms share a benign, self-terminating course; they differ in the stimulus that sets them off, the colour the child turns, and the physiology that drives them.

MNEMONIC

Blue with rage, pale with fright

The **cyanotic** child turns blue and is set off by anger or frustration; the **pallid** child turns pale and is set off by pain or fear. The colour names the type, and the colour points at the mechanism: cyanosis follows the held breath, pallor follows the vagal drop in heart rate.

41.4 Etiopathogenesis: why the reflex fires

The cause is multifactorial, and one strand of it is treatable. No single lesion explains breath-holding spells; the current understanding is that several immature or dysregulated systems converge to produce the reflex. **Autonomic nervous system dysregulation** underlies both types, with the pallid form in particular reflecting **vagally-mediated cardiac inhibition**, a reflex asystole or profound bradycardia mediated by an overactive vagal response to the provoking stimulus. Contributing to this immaturity is **delayed brainstem myelination**, consistent with the age window in which the spells appear and then remit as the nervous system matures. The strand that changes management is **iron deficiency anaemia**, which is associated with breath-holding and whose correction can reduce the frequency of spells, giving the clinician something to treat beyond reassurance. The mechanisms sit together rather than competing:

- autonomic dysregulation, the shared final common pathway of both types;
- vagally-mediated cardiac inhibition, the reflex asystole that defines the pallid spell;
- delayed brainstem myelination, fitting the infantile onset and the spontaneous resolution;

- iron deficiency anaemia, the one contributor that is worth actively seeking and correcting.

IN INDIA

Iron deficiency anaemia is highly prevalent among Indian infants and young children, which makes the iron strand of the etiology far more than a footnote in this setting. A child presenting with breath-holding spells warrants an assessment of iron status, and correcting a documented deficiency is a rational, low-risk intervention that can reduce the frequency of episodes. In a population where nutritional anaemia is common, this converts an otherwise "reassure and wait" condition into one with a concrete, treatable contributor worth pursuing.

41.5 Telling it apart from epilepsy, and managing it

The spell that imitates a seizure is not one. The central differential, and the one the examination targets, is the epileptic seizure. Breath-holding is a **nonepileptic** seizure-like behaviour: it is invariably preceded by a provoking stimulus and a cry or a fright, it never arises out of sleep, the loss of consciousness is brief and colour-linked, and recovery is immediate and without a post-ictal state. A genuine seizure has none of this dependence on provocation, can occur in sleep, and is typically followed by drowsiness or confusion. A prolonged pallid spell may end in a few anoxic jerks, and this is exactly where the unwary reach for an anticonvulsant, but the jerks are the consequence of transient cerebral hypoxia from the vagal asystole, not the expression of an epileptic focus. Management follows from the benign, self-limiting nature established above: confident reassurance and explanation are the cornerstones, the family is taught that the spells cause no harm and will remit, and any underlying contributor, iron deficiency in particular, is treated. Drugs directed at the brain are not indicated for the spells themselves.

TRAP **Diagnosing epilepsy and starting an anticonvulsant.** A pallid spell with a few terminal jerks, described second-hand by a frightened parent, is the classic set-up. Candidates who anchor on the convulsive movements and miss the provoking fright, the pallor and the instant recovery will label a seizure and prescribe accordingly, exposing the child to an unnecessary drug for a benign reflex. The discriminating features are the invariable trigger, the absence of sleep-onset events, and the immediate, post-ictal-free recovery.

PITFALL

The commonest clinician-and-family error is not misdiagnosis but management by appeasement. Once parents learn that a tantrum can escalate into a frightening spell, they begin to give the child whatever prevents the frustration, and the surrounding behaviour, though not the reflex itself, is powerfully reinforced. Advising a family to yield to the child in order to avert spells trades a benign, self-limiting reflex for an entrenched behavioural pattern. The guidance is the opposite: handle the trigger calmly and consistently, and do not let the fear of a spell dictate the parenting.

41.6 The wider family of transient childhood behavioural phenomena

Most of childhood's odd behaviours are developmental, not pathological. Breath-holding belongs to a larger group of transient phenomena of early childhood that share a benign, self-limiting character: the ordinary temper tantrum, thumb-sucking, nail-biting, rhythmic habits

such as body-rocking and head-banging at sleep onset, and the brief motor mannerisms of the toddler years. The unifying clinical principle is that each is common, developmentally expected, and outgrown, and that the intervention of first resort is explanation and reassurance rather than treatment. The examiner's interest here is judgement: knowing when a behaviour sits within normal limits and when its intensity, persistence or associated impairment lifts it into a disorder that is taught in its own right. The threshold at which repetitive or rhythmic behaviour ceases to be a benign habit and becomes a stereotypy or a tic, and the boundaries of the individual childhood disorders, are drawn where those topics are taught; the discipline in this section is to recognise the transient phenomenon, place it, and resist the urge to medicalise it. The general developmental context for what is age-appropriate belongs to the Normal child development and milestones notes.

Breath-holding spells are involuntary, benign, self-limiting reflexes of early childhood, not wilful acts and not epilepsy; recognise the trigger-bound pattern, exclude the seizure, treat any iron deficiency, and reassure.

Discriminate, apply and consolidate

42 · Telling the disorders apart, and from normal limits

The marks in this section are not for knowing a disorder but for telling it from its neighbours. By the time a candidate reaches this point the individual entities have each been learned in their own place, and the temptation is to treat that as the finish. It is not, because the examined presentation is almost never a clean single disorder announcing its name. It is a disruptive, irritable, rule-breaking child, or a frightened, clingy, wet one, described in a paragraph that fits three or four diagnoses at once and one normal childhood at the same time. The work that earns the marks is the sorting: seeing which axis a presentation turns on, which nearest neighbour it must be held against, and whether it is a disorder at all. This section does that work once, across the whole chapter, using only what the preceding entities have already established.

Two discriminations carry most of the weight, and the chapter has been built to set them up. The first is internal to the behavioural group: the several ways a child can present as disruptive look alike from across the room and separate only on the quality of what is happening underneath. The second runs the length of the chapter: nearly every symptom here also exists as an ordinary part of growing up, so each disorder has to be told not only from its diagnostic neighbours but from its own normal counterpart. Both are done here as maps rather than as fresh teaching, because the point of a synthesis is to lay finished pieces side by side.

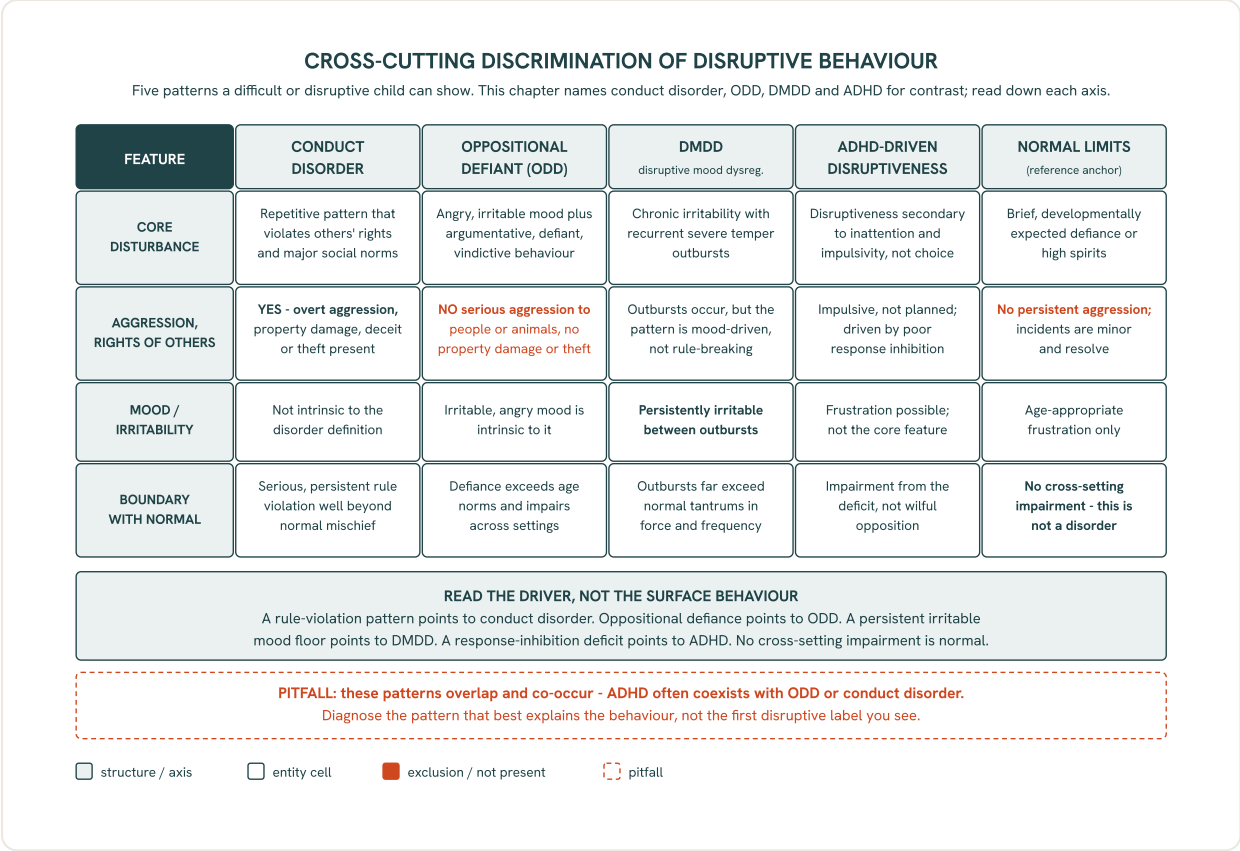

Fig 23.31. Cross-cutting discrimination of disruptive behaviour: conduct disorder, oppositional defiant disorder, DMDD, ADHD-driven disruptiveness and normal-limits behaviour separated on core disturbance, aggression, mood and the boundary with normal development.

42.1 The disruptive-behaviour differential: four disorders and one normal childhood that all look alike

Disruptiveness is a final common presentation, not a diagnosis. A great many child referrals arrive as some version of the same complaint: the child is difficult, defiant, aggressive, will not do as told, and is trouble at home or at school. That surface is shared by several distinct conditions, and the examined skill is to look past it to what the behaviour actually is. Four disorders and one band of normal development converge on this presentation, and each has been taught in full elsewhere in this chapter or its neighbours: **conduct disorder**, in which the defining feature is that the line crossed is other people's basic rights and major age-appropriate norms; **oppositional defiant disorder**, in which the pattern is an angry, argumentative and defiant stance aimed largely at authority figures, without that step into violating others' rights; **disruptive mood dysregulation disorder**, in which the outbursts sit on top of a persistently irritable and angry mood between them and the condition is at bottom a disorder of mood rather than of conduct; and the disruptiveness that is **secondary to attention-deficit/hyperactivity disorder**, where rules are broken through failure of regulation and impulse rather than through hostile intent, taught in the ADHD and specific learning/communication disorders notes. Against all four stands the ordinary difficult behaviour of a well child, which is the fifth thing the paragraph might be describing and the one most often forgotten.

None of these is re-taught here; each owning section carries its own criteria, and the local contrasts a candidate meets first - conduct disorder against oppositional defiant disorder,

disruptive mood dysregulation disorder against paediatric bipolar disorder - are drawn where those disorders live. What the synthesis adds is the single grid that holds all five at once, so that a mixed vignette can be resolved by asking, in order, what kind of thing the behaviour is.

42.2 Reading the grid: the axes that actually separate them

The five separate on a small number of questions, asked in the right order. The grid below is not a list of features to match but a sequence of discriminating axes. The first and most powerful is the nature of the line the behaviour crosses. The second is whom the behaviour is aimed at and whether an abnormal mood is present between episodes. The third, applied last, is whether the picture clears once the developmental baseline and the setting are taken into account, which is the question that separates every one of the disorders from normal difficult behaviour.

PRESENTATION	WHAT THE BEHAVIOUR ESSENTIALLY IS	THE DISCRIMINATING QUESTION	MOOD BETWEEN EPISODES
Conduct disorder	Violation of others' basic rights and major societal norms - aggression, destruction, deceit, serious rule-breaking	Is the line crossed other people's rights, not merely adult authority?	Not the defining feature
Oppositional defiant disorder	An angry, argumentative, defiant and often vindictive stance toward authority	Is defiance of authority the ceiling, without rights-violation?	Irritability is part of the pattern but is not a sustained mood disorder
Disruptive mood dysregulation disorder	Severe recurrent temper outbursts on a background of persistent irritable, angry mood	Is the mood between the outbursts itself persistently irritable?	Persistently and observably irritable or angry
Disruptiveness secondary to attention-deficit/hyperactivity disorder	Rule-breaking driven by inattention, impulsivity and overactivity, not hostile intent	Is the trouble a failure of regulation rather than of intent?	Not primarily a mood problem
Difficult behaviour within normal limits	Age-expected defiance, temper or rule-testing, situational and outgrown	Does it clear once age, setting and impairment are weighed?	Age-appropriate, not sustained

The disruptive-behaviour differential as one grid. Each row's full criteria are taught in its own place; what is set out here is the order of questions that resolves a shared surface into one of five answers. The comparison is read down the third column.

Read this way the differential becomes a decision rather than a memory test. A hostile, aggressive boy who steals and intimidates has crossed into others' rights and points to conduct disorder; the same-looking boy who argues, defies and loses his temper with adults but does not cross that line points to oppositional defiant disorder; the child whose outbursts erupt from a mood that stays sour and irritable in between points to disruptive mood dysregulation disorder; the child who breaks rules because he cannot sit, wait or attend points back toward attention-

deficit/hyperactivity disorder as the primary problem. And a good many children fitting none of these are simply behaving as their age allows.

TRAP **Collapsing every disruptive child into conduct disorder.** Aggression and rule-breaking pull the eye straight to the most severe label, and the weaker answer stops there. The disciplined answer asks what the behaviour actually is before naming it: defiance of authority is not violation of rights, a temper outburst from a persistently irritable mood is a mood disorder and not a conduct one, and dysregulated impulsivity is a disorder of regulation. Naming conduct disorder because the child is difficult, rather than because others' basic rights are being violated, is the single commonest error this part of the chapter tests.

42.3 Disorder against normal limits: the cross-cutting map

Every family in this chapter has a normal counterpart it must be told from. The developmental continuum was set out at the opening as the principle underneath the whole chapter, and it comes due here, because the second great discrimination is not between two disorders but between a disorder and ordinary childhood. Tantrums, separation distress, fears, bedwetting and repetitive self-soothing are not abnormal in themselves; they are expected at particular ages and present in well children. What lifts any of them out of normal development and into a diagnosis is not the behaviour but four features acting together, the same four the chapter has used throughout: whether it is **persistent** rather than a phase, **pervasive** across settings rather than confined to one, developmentally out of step for the child's age, and genuinely **impairing**. Each owning section fixes its own threshold in numbers; the map here holds the comparisons together so the levers can be seen doing the same work every time.

NORMAL DEVELOPMENTAL PHENOMENON	THE DISORDER IT MUST BE TOLD FROM	WHAT LIFTS IT OUT OF NORMAL LIMITS
Toddler and preschool temper tantrums	Oppositional defiant disorder	A persistent, pervasive defiant and irritable pattern continuing past the age tantrums subside, impairing across settings
Separation distress of infancy and early childhood	Separation anxiety disorder	Separation fear excessive for the child's age, persistent, and impairing rather than a self-limiting developmental stage
Age-typical fears (dark, strangers, animals, imaginary threats)	The childhood anxiety disorders	Fear out of proportion to the threat, persistent, and disabling day-to-day function
Bedwetting before continence is developmentally expected	Enuresis	Wetting continuing beyond the developmental age of expected continence, at the criterion frequency and duration
Benign repetitive self-soothing (rocking, thumb-sucking)	Stereotypies and tic disorders	Movements that are prolonged, fixed and impairing, distinguished from the sudden non-rhythmic character of tics

The normal-limits map across the chapter. Each disorder's exact threshold is taught in its own section and is deliberately named here without its numbers; the constant is the set of levers in the third column, which do the same job for every row.

The map is worth carrying whole because the same reasoning recurs in disguise. A three-year-old having tantrums, a toddler distressed at a parent's departure, a five-year-old frightened of the dark, a young child still wet at night, and an infant who rocks to settle are, far more often than not, well children doing what their age allows. The corresponding disorder is diagnosed only when the four levers pull together, and the exact age or frequency that anchors each threshold belongs to the section that owns it and to the Normal child development and milestones notes.

RULE **A behaviour never makes a childhood diagnosis; persistence, pervasiveness, developmental incongruence and impairment do.** The presence of a tantrum, a fear, a wet bed or a defiant refusal settles nothing on its own, because each is a normal event at some age. The diagnosis lives in whether the behaviour has become durable, generalised across settings, out of step for the age, and a genuine source of impairment. Read every childhood presentation through those four levers before reaching for a label.

PITFALL

The error here is the mirror of missing a disorder: over-diagnosing ordinary development. A firm parent, an anxious teacher or a crowded clinic can turn an age-appropriate tantrum, a normal separation protest or a still-maturing bladder into a referral and then into a label. Reaching for a diagnosis because the behaviour is present, rather than because it is persistent, pervasive, developmentally out of step and impairing, over-pathologises childhood and does its own harm. The two failures - under-recognising the genuine disorder and over-labelling the normal child - are opposite ends of the same missing judgement.

42.4 Putting the chapter's map to work

The two discriminations run on one underlying method. Whether the question is which disruptive disorder a child has or whether he has one at all, the move is the same: refuse the surface, name the axis the presentation turns on, and hold it against both its nearest diagnostic neighbour and its normal counterpart before committing. That method is what lets a single mixed vignette be answered cleanly, and it is why the chapter was built as a shape rather than a list. A candidate who carries the family map, the disruptive-behaviour grid and the normal-limits levers into the hall can take almost any child presentation the paper offers and place it, which is precisely what these marks reward.

- Sort the presentation into its family first, and notice when it straddles two - the acting-out child hiding an internalising disorder is the commonest such crossing.
- Within the behavioural group, ask what the behaviour essentially is - rights, authority, mood or regulation - before naming a disorder.
- For any symptom with a normal counterpart, apply the four levers before diagnosing, and be as willing to withhold a label as to give one.
- Cross-refer outward where the presentation reaches beyond this chapter, to attention-deficit/hyperactivity disorder and to the wider systems of assessment and protection, rather

than forcing the answer to stay inside these pages.

IN INDIA

Two features of Indian practice sharpen both discriminations. The operative classification is ICD-11, so the disruptive-behaviour labels that reach case files are its dissocial and oppositional categories rather than the DSM names, and the reasoning of the grid transfers unchanged even though the wording differs. More consequentially, most of these children are first seen by a paediatrician, a general physician or a school rather than a child psychiatrist, in a setting with few dedicated child mental health services. That raises the stakes on the normal-limits map in both directions: a genuinely disordered internalising child is easily missed because the distress is quiet, while an ordinary tantruming or bedwetting child is easily over-labelled by an anxious family or an overburdened clinic. The synthesis is not an academic tidy-up here; it is what protects the well child from a diagnosis and the unwell one from being overlooked.

GOOD TO REMEMBER

Before writing any childhood diagnosis, name its two comparators out loud: the nearest disorder it could be confused with, and the normal developmental phenomenon it grows out of. If the presentation cannot be told convincingly from both, the label is not yet earned. This single habit prevents the two errors that dominate this chapter's examined material at once.

MNEMONIC

Family, then Axis, then the four Levers

The chapter's whole method in three moves. First place the child among the five **Families** seeded at the outset - distress turned Out and distress turned In, with the tic, attachment, and elimination and feeding disorders apart. Then, within the disruptive group, read the **Axis** the behaviour turns on: whether it is about others' rights (conduct disorder), authority (oppositional defiant disorder), mood (disruptive mood dysregulation disorder) or regulation (attention-deficit/hyperactivity disorder). Last, before any label, pull the four **Levers** that separate every disorder from its normal counterpart: persistent, pervasive, developmentally out of step, and impairing.

Refuse the surface: place the child in a family, read what the disruptive behaviour essentially is - rights, authority, mood or regulation - and gate every childhood diagnosis through the four levers of persistence, pervasiveness, developmental incongruence and impairment before you name it.

Rights	Authority	Mood	Regulation
CONDUCT DISORDER	OPPOSITIONAL DEFIANT DISORDER	DISRUPTIVE MOOD DYSREGULATION DISORDER	ADHD-DRIVEN DISRUPTIVENESS

43 · Worked vignettes across the five groups

A map is only as good as the child in front of you. Everything set out across this chapter has been taught one disorder at a time, each in its own place and against its own threshold. The

examination does not ask questions that way. It hands you a paragraph about a real-seeming child and asks you to do, under time, what a clinician does across a first consultation: hear a presenting complaint, recognise which family of disorder it belongs to, read it against what is normal for that age, look for what travels alongside it, and land on a discriminator before committing to an answer. The worked cases below rehearse exactly that movement. They are deliberately built to be entered through the loudest symptom, because that is how children actually arrive, and then to turn on the quieter fact that decides the diagnosis.

Each vignette is arranged around one of the chapter's five families, so that the set as a whole demonstrates the spine already laid down: distress turned outward and distress turned inward as one axis, and the tic, attachment, and elimination-and-feeding disorders standing apart from it with their own logic. None of these cases re-teaches a disorder; where the full criteria, doses and course live, this chapter has already set them out, and the vignette only points back to that place. The work here is the reasoning between symptom and label, which is the part a candidate most often skips and an examiner most reliably tests.

43.1 The behavioural door: aggression that may be more than conduct

A defiant, aggressive boy is the commonest externalising vignette, and the commonest trap. Consider a school-age boy brought by a worn-out mother because he fights, lies, breaks rules at home and at school, and will not be told. The loudest reading is a disruptive behaviour disorder, and the first real task is to place it: a pattern of serious rights-violating and rule-breaking conduct points one way, while argumentativeness, temper and defiance directed at authority without that serious violation points to the milder oppositional pattern. That distinction is drawn in full where each disorder is taught, and the vignette only requires you to know which set of behaviours you are reading. A stronger answer then asks whether the boy shows the **callous-unemotional** features that mark the limited-prosocial-emotions variant, because they change the prognosis and the plan, and are set out where the conduct disorder specifier is taught rather than re-listed here.

The decisive move, and the one that separates a safe candidate from a fluent-but-shallow one, is to refuse to stop at the behaviour. The child who acts out is the child most likely to be carrying an anxiety, trauma or mood disorder underneath, presenting through irritability and rule-breaking that look purely behavioural. Ask, deliberately, what sits beneath the conduct. The hyperactive, impulsive overlap that so often accompanies this picture belongs to the ADHD and specific learning/communication disorders notes, and is named here only so that you screen for it rather than fold it into a behavioural label.

> **GOOD TO REMEMBER**
>
> When a child arrives through the behavioural door, treat the referral as telling you which door the family came through, not the whole of what is inside the room. The acting-out presentation earns a deliberate screen for the anxiety, trauma and mood that hide behind conduct, and for the attentional problem that so often rides with it. The loudest symptom is a starting point, never the finish.

43.2 The emotional door, arriving in the body: pain, and the child who will not go to school

Internalising distress is referred late, quietly, and often through the body. Consider a child with recurrent morning stomach aches and headaches who becomes distressed at the school gate and stays home, yet is well and cheerful on weekends and holidays. The physical complaints are genuine and the family may have cycled through paediatric investigations before anyone asks about mood or fear. This is the **somatisation** presentation of childhood distress, the way anxiety and depression declare themselves in a child who has few words for either, and its full teaching sits where the somatic-symptom and pain presentations of childhood are set out in this chapter. The candidate names it and moves to the discrimination the vignette is really testing.

That discrimination is between two ways a child ends up out of school. **School refusal** is anxiety-driven: the child is at home, the parents know, and the anxiety is often about separation, about the school situation itself, or about a mood disorder pulling the child down. **Truancy** is conduct-driven: the child conceals the absence and is elsewhere, and it belongs with the externalising picture of the section above. The features that separate them are worth holding as a short set:

- whereabouts and parental knowledge: at home with the family versus concealed and elsewhere;
- the affect that drives it: fear and distress versus indifference or defiance;
- the company kept: alone or clinging to a caregiver versus with a peer group away from adults;
- and the family the disorder belongs to: emotional and internalising versus behavioural and externalising.

Behind the refusal, the candidate looks for the specific anxiety or mood disorder generating it, each taught in its own place in this chapter, and for the masked, irritable presentation that childhood depression so often takes. The general adult somatic-symptom and conversion entities, which are a different construct from this childhood somatisation, are the province of the Somatic-symptom, sexual, impulse-control disorders and suicide notes.

43.3 A neurodevelopmental door: movements and sounds that are not habits

The tic vignette is won on phenomenology, not on the movement itself. Consider a boy whose parents describe eye-blinking and throat-clearing that have waxed and waned over months, now joined by brief involuntary sounds, worse when he is tired or stressed, briefly suppressible with effort, and preceded by an uncomfortable urge that the movement relieves. That signature is a tic disorder, and the vignette is testing whether you can separate it from its mimics rather than whether you can name Tourette. The discriminating features cluster tightly: the **premonitory urge**, the brief voluntary suppressibility at a cost, the waxing-and-waning course, and the aggravation by stress and fatigue. Where the classification of tic disorders and the phenomenology of Tourette are set out, this is taught in full; the vignette needs only the recognition.

Against that signature the candidate lines up the look-alikes and lets each fall away. **Stereotypies** are rhythmic, fixed, self-soothing and typically begin earlier, often in a child with autism or intellectual disability, and lack the urge-and-relief quality. Chorea is flowing and non-

suppressible; dystonia is sustained and postural; a compulsion is performed to neutralise an intrusive thought rather than to relieve a bodily urge. Each of these separations is developed where tics are differentiated from other movements, and the vignette rewards knowing which single feature does the work in each case. The impairment in such a child, when it comes, is usually driven less by the tics than by the attention-deficit and obsessive-compulsive problems that so commonly accompany them; those comorbidities are named here and taught, respectively, in the ADHD and specific learning/communication disorders notes and the Anxiety, OCD and trauma-related disorders notes.

TRAP **Reading suppressibility as proof that the movements are voluntary.** A child who can briefly hold a tic down, or a parent who reports that he "can stop when he wants to," tempts the candidate to call the movements a habit or attention-seeking behaviour. Brief, effortful, uncomfortable suppressibility followed by a rebound is a defining property of a tic, not evidence against it, and the premonitory urge is precisely what makes suppression cost something.

43.4 A relational door: the child who came from an institution

Two children from the same depriving start present as mirror images. Consider a young child adopted after early institutional care. One is watchful and emotionally withdrawn, does not seek comfort when distressed and does not respond to it when offered, and shows little social or emotional reciprocity. Another, from a similar history, is strikingly over-familiar, wanders off with unfamiliar adults without checking back, and shows no wariness of strangers. The first is the emotionally withdrawn, internalising pattern; the second is the indiscriminate, disinhibited pattern. The **reactive attachment disorder** and **disinhibited social engagement disorder** that these two pictures represent are each taught in full in their own place; the vignette tests whether you read the direction of the disturbance correctly and, crucially, whether you anchor both to their required cause.

That cause is a history of **pathogenic care**, grossly insufficient or repeatedly disrupted caregiving, and it is what turns this from a temperament question into an attachment one. The discrimination the examiner is usually reaching for is from autism: the socially odd, poorly reciprocal post-institutional child can look autistic at a glance. What separates them is the pathogenic-care history itself, the tendency to improve once a stable and sensitive caregiver is in place, and the absence of the restricted, repetitive repertoire and the pervasive social-communication deficit that define autism. That attachment-side comparison is developed where RAD and DSED are differentiated from autism in this chapter; autism itself is the subject of the Intellectual disability and autism spectrum disorder notes and is not re-taught here. The management follows from the cause and is not pharmacological: a stable, responsive caregiving relationship is the intervention, developed where the attachment disorders' management and the effects of institutional care are set out.

43.5 A bodily-function door: the bed that is wet, and the food that keeps shrinking

Two brief cases share a family. First, a child who still wets the bed at night. The whole discrimination turns on the developmental baseline: at one age this is ordinary and expected, and at a later age, persistent and frequent, it is a disorder, with the exact threshold taught where

enuresis is classified and assessed. The vignette rewards asking the age and the pattern before reaching for a label, and it hides a genuine clinical danger in its treatment.

> **PITFALL**
>
> The tricyclic used for enuresis is cardiotoxic in overdose, and the therapeutic-to-toxic margin in a small child is narrow. Reaching for imipramine casually, or leaving a supply within a young child's or a sibling's reach, is the way this benign-seeming problem turns dangerous. The dose, the cautions and the safer first-line options are set out where the management of enuresis is taught; the point to carry from the vignette is that the drug is not a soft option and the first line is behavioural.

Second, a child whose eating has narrowed to a few textures and who is losing weight, but who has no fear of fatness and no disturbance of body image. This is the picture of **avoidant restrictive food intake disorder**, driven by sensory aversion, low interest in eating, or fear of a feared consequence such as choking, and it is discriminated from anorexia and bulimia precisely by the absence of the weight-and-shape motive. ARFID and that distinction are taught in full in their own place; anorexia and bulimia themselves belong to the Eating and sleep-wake disorders notes and are named here only as the contrast. The younger child eating non-food substances, and the infant regurgitating and re-chewing, are the other members of this bodily-function family, each taught where it sits.

43.6 Pulling the doors together: one method for any child

Every vignette above was entered through a door and decided somewhere else. The loud presenting symptom named a family; the diagnosis was settled by a quieter discriminator and by reading the child against a developmental baseline that keeps moving. That is the single transferable method, and it is worth seeing all five cases laid against it at once.

PRESENTING DOOR	FAMILY	THE DISCRIMINATOR THE CASE TURNS ON	WHERE IT IS TAUGHT IN FULL
Aggression, defiance, rule-breaking	Behavioural (externalising)	Severity of rights-violation, the callous-unemotional variant, and what internalising disorder hides beneath	Where conduct and oppositional disorders are set out
Recurrent pain, will not go to school	Emotional (internalising)	Anxiety-driven refusal versus concealed truancy; somatisation as the presenting language	Where the childhood anxiety, mood and somatic presentations are set out
Waxing movements and sounds, briefly suppressible	Tic disorders	Premonitory urge and suppressibility against stereotypy, chorea, dystonia and compulsion	Where tic classification and Tourette are set out
Withdrawn, or overfamiliar, after early deprivation	Attachment disorders	The pathogenic-care history, and improvement with a stable caregiver, against autism	Where the attachment disorders and their differentiation are set out
Bedwetting; narrowed, weight-losing eating	Elimination and feeding	Age against the developmental baseline; absence of a weight-and-shape motive in ARFID	Where enuresis and the feeding disorders are set out

The five worked cases read against the one method: a presenting door names the family, a quieter discriminator settles the diagnosis, and the full teaching lives in each disorder's own place.

RULE **The presenting complaint names the door, never the diagnosis.** The loudest symptom reliably tells you which of the five families you are in, and reliably fails to tell you which disorder within it, or what else the child is carrying. Read every childhood vignette by placing the family from the presenting picture, reading the picture against the developmental baseline for that age, screening across the outward-inward axis for what hides beneath, and only then committing to the discriminator that the case actually turns on.

IN INDIA

Which door a child reaches care through is shaped by the setting. In a family-based, service-scarce system these children very often meet a paediatrician, a general physician or a school first, and the externalising presentations, which trouble the adults around the child, arrive far more readily than the internalising ones, which cause the child the greater private suffering and are the likeliest to go unrecognised. The labels in the case file are usually ICD-11's rather than the DSM equivalents. The examination vignette written for Indian candidates leans, accordingly, on the presentations that reach an Indian clinic, and the method above is what lets you answer them without a specialist's caseload behind you.

MNEMONIC

Out, In, and three apart

The whole set of vignettes cashes in the chapter's spine. Two families share one axis: the child who turns distress **Out**, met in the behavioural case, and the child who turns it **In**, met in the emotional case that arrived through the body. **Three** families stand **apart** with their own logic: the tic disorders (neurodevelopmental and motor), the attachment disorders (relational, rooted in early care), and the elimination and feeding disorders (of bodily function). Place the child among those five, read against the developmental baseline, and the vignette becomes answerable.

Door	Baseline	Across	Home
THE LOUDEST SYMPTOM NAMES THE FAMILY	READ IT AGAINST DEVELOPMENTAL AGE	SCREEN THE OTHER SIDE OF THE AXIS	THE DISCRIMINATOR SETTLES THE LABEL

A childhood vignette's presenting door names the family, never the diagnosis: place the child among the five families, read the picture against the moving developmental baseline, screen across the Out-In axis for what hides beneath, and commit only to the discriminator the case actually turns on.

44 · Consolidation and active recall

The last hour before an examination is not the time to learn a disorder; it is the time to make sure you can find one. Everything in this chapter has by now been taught in full, each entity in its own place, with its criteria, its mechanism and its management. What has not yet been done, and what decides the marks, is the retrieval: whether the shape of the chapter is available to you under pressure, so that a mixed child presentation resolves into the right family and the right discrimination rather than into a blank or a guess. This closing section does no new teaching. It hands back the whole set as one structure, gives you a way to test that the structure is genuinely yours rather than merely familiar, and leaves you with the single mnemonic the chapter was built to earn.

Read what follows as a rehearsal rather than a summary. A summary you nod along to and forget; a rehearsal makes you produce the answer before you are allowed to see it, and that act of producing is what fixes the material and what an examiner is, in effect, paying you to be able to do.

44.1 Why the close is retrieval and not re-reading

Knowing that you have read something is not the same as being able to produce it. The most reliable finding in the psychology of learning, and the one most useful on the evening before a paper, is that **active recall** - deliberately generating an answer from memory - consolidates knowledge far more durably than re-reading, however attentive the re-reading feels. Re-reading breeds a sense of mastery that outruns the reality, because a page you have seen before is easy to process, and the ease is misread as knowledge - the **fluency illusion** that quiet revision generates and that active production dispels. Producing the answer with the page shut removes that

comfort and shows you, honestly, where the gaps are while there is still time to close them. This is why the heart of this section is a list of prompts with no answers printed beside them, and why you should resist the pull to treat them as trivia you already know.

RULE **Retrieve before you re-read.** When a prompt stops you, the instinct is to turn back to the section and read it again; the stronger move is to sit with the difficulty, reconstruct as much as you can from the family shape, and only then check. The struggle to retrieve, not the smoothness of the re-reading, is what makes the item available next time.

44.2 The whole chapter as one shape

Five families, and for each the single question the examination turns on. The chapter opened by resolving a loose-looking list into five families on two principles; it closes by reassembling them, but now keyed to retrieval. For each family the useful thing to carry is not the full criteria - those are taught where they belong - but the **discriminating question**, the pivot on which the marks in that family actually turn. The map below sets the five side by side against that pivot. It names the disorders it compares and does not re-teach them; the cross-cutting comparison that works those distinctions in detail is drawn earlier in this chapter, and the point here is only to have the pivots in a single view.

FAMILY	THE PIVOT THE MARKS TURN ON	THE DISCRIMINATION IT FORCES (TAUGHT IN FULL EARLIER)
Behavioural (externalising)	What is the behaviour violating - a rule, another person's rights, or the child's own mood control?	Oppositional defiant disorder against conduct disorder against disruptive mood dysregulation disorder, and each against the disruptiveness that rides with attention-deficit/hyperactivity disorder
Emotional (internalising)	Is the fear, worry or low mood developmentally expected, or persistent, pervasive and impairing for this age?	The separation, social and specific presentations of childhood anxiety, and childhood depression with its irritable and somatic disguises
Tic disorders	Is the movement involuntary and urge-driven, or purposeful and self-soothing?	Tics against stereotypies, chorea, dystonia and compulsions
Attachment disorders	Is there a history of grossly deficient care, and does the child withdraw or approach indiscriminately?	Reactive attachment disorder against disinhibited social engagement disorder, and both against autism spectrum disorder
Elimination and feeding	Is the bodily-function problem beyond the age at which it is expected, and is it wet, soiled, restricted or aberrant?	Enuresis and encopresis against age-appropriate continence; pica, rumination and avoidant/restrictive intake against the eating disorders proper

The five families reassembled for the close, each against the one question that carries its marks. The disorders are named, not re-taught; the detailed discriminations sit in their own sections and in the cross-cutting comparison drawn earlier in this chapter.

The map is a route back into the detail, not a substitute for it. Its use in the examination is fast and specific: a vignette lands, you place it into one of the five families within a sentence, and the family hands you its pivot, which is the question you must be seen to ask. A candidate who can name the family and state its pivot has already structured the answer; the remembered criteria then hang off that structure instead of arriving as an unsorted heap. Two families - the behavioural and the emotional - answer to the single outward-inward axis; the other three keep their own logic, and forcing them onto that axis is the error the opening warned against and the close will not undo.

44.3 The active-recall prompts, by family

Cover the section, answer aloud, then check. These are deliberately answer-free. Work them with the relevant section shut: say the answer out loud or write it, and only then open the chapter to mark yourself. A prompt you glide past with a vague nod is a prompt you have not passed. They run in the chapter's own order, one cluster per family, and each cluster asks you to produce the discrimination that the family's pivot demands.

Behavioural. How does defiance without aggression differ from the violation of others' rights, and how does chronic, non-episodic irritability differ from both? Which onset pattern of the aggressive disorder carries the worse trajectory, and toward which adult disorder does it point? What does the callous-unemotional pattern add, and why does it change the prognosis rather than the diagnosis?

Emotional. On what single feature does a childhood fear become a disorder rather than a stage? How does depression disguise itself in a child who never says he is sad? When a child complains only of stomach aches and headaches, which two internalising disorders should you actively look for behind the body, and why is that presentation not the same thing as the somatic symptom and conversion disorders proper?

Tic. What distinguishes an involuntary, urge-driven movement from a purposeful, rhythmic, self-soothing one, and which two comorbidities so define the fuller tic phenotype that they, more than the tics, drive the impairment? Why is the first-line treatment of tics behavioural rather than pharmacological?

Attachment. What single element of the history is required before either attachment disorder can be considered at all? How does the emotionally withdrawn pattern differ from the indiscriminately sociable one, and what tells both of them apart from the superficially similar social difficulty of autism spectrum disorder?

Elimination and feeding. At what point does wetting or soiling stop being a stage and become a disorder, and which of the enuresis treatments is the order-of-magnitude and cardiotoxicity trap in a child? What separates avoidant and restrictive eating from the eating disorders driven by body image?

TRAP **Mistaking recognition for recall.** Reading a prompt, thinking "yes, I know that", and moving on is the commonest self-deception of the last evening. **Recognition**, the sense that you have met an idea before, is a far weaker signal than being able to generate it cold, and the examination asks only for the second. If you did not actually say or write the answer, treat the prompt as unpassed and come back to it.

44.4 What the paper actually asks of this chapter

The marks reward placement and discrimination, not recitation. Very little in a child-psychiatry question is won by reproducing a criteria list intact. The examinable move, almost every time, is to take an untidy real-child presentation, place it in its family, and then draw the one discrimination that the family turns on - defiance from rights-violation from mood-driven irritability, expected fear from disorder, tic from stereotypy, deprivation-rooted attachment disturbance from autism, developmental wetting from enuresis. This is why the map and the prompts above are built around pivots rather than around definitions: the definitions are the raw material, and the discrimination is the finished answer. The child who sits visibly on one side of the outward-inward axis and quietly on the other is **the mixed presentation** to expect, and the answer that notices both sides is the one that scores.

IN INDIA

Two features of local practice should shape how you carry this chapter into the paper. First, the operative classification here is ICD-11, so the family names and category labels you produce should be its labels, even where the teaching above has moved between systems for clarity. Second, these children very often reach a paediatrician, a general physician or a teacher long before a child psychiatrist, and the outward-inward axis predicts which of them arrive at all: the disruptive, externalising presentations are brought in because they trouble the adults, while the internalising disorders, which cause the child the greater private suffering, are the ones a service-scarce system most readily misses. An answer that names where a disorder is likely to be first seen, and by whom, reads as clinically grounded rather than merely memorised.

PITFALL

The revision-stage error is to spend the final hours deepening the disorders you already know and avoiding the discriminations you find slippery, because the familiar material is pleasant to re-read and the slippery pairs are uncomfortable to work. This inverts the return on effort. The marks lost in this chapter are lost at the boundaries - conduct disorder against oppositional defiant disorder against disruptive mood dysregulation, the attachment disorders against autism, tics against stereotypies - and it is precisely the uncomfortable pairs, not the comfortable entities, that repay the last hour.

44.5 The one shape to carry in

If everything else falls away under pressure, this is what should remain. The chapter was built so that a single memorable shape would survive the examination hall even when individual criteria did not. It is the frame the opening laid down and every section since has filled: two families that share one axis and three that stand apart from it, all read against a **developmental**

baseline that keeps moving as the child grows. Hold that, and any presentation has somewhere to go before you have recalled a single threshold.

MNEMONIC

Out, In, and three apart

The child who turns distress **Out** is the behavioural, externalising group; the child who turns it **In** is the emotional, internalising group; these two share one axis. **Three** families stand **apart** from that axis with their own logic: the tic disorders (neurodevelopmental and motor), the attachment disorders (relational, rooted in deficient early care), and the elimination and feeding disorders (of bodily function). Every one of the five is judged against the developmental baseline, never against the behaviour alone. Five families, two principles, one shape.

GOOD TO REMEMBER

On the day, lead with the family, not the diagnosis. Placing a presentation as behavioural, emotional, tic, attachment or elimination-and-feeding takes a sentence and immediately narrows the field to the discriminations that matter, which is the ground the marks are on. Reaching first for a specific label invites the loudest symptom to capture the answer; reaching first for the family keeps the discrimination in view.

The prompts are only useful if they are worked rather than read, so a short method for running them:

- take one family at a time and shut the section before you begin;
- say or write the answer in full before you look, treating any prompt you only recognise as unpassed;
- check against the family map above, confirming you produced the pivot and not merely a definition;
- return to the pairs that stopped you after a gap of some hours rather than immediately, so the second retrieval is a genuine test;
- and leave the comfortable entities to last, spending the scarce final time on the uncomfortable boundaries.

Two families on one axis - distress turned Out (behavioural) against distress turned In (emotional) - and three families apart from it (tic, attachment, elimination and feeding), every disorder read against the moving developmental baseline: place the family first, then draw the discrimination its pivot demands.

Out	In	Apart
PLACE IT: WHICH FAMILY?	ASK IT: WHAT IS THE PIVOT?	DRAW IT: WHICH DISCRIMINATION?

Previously asked

Genuine past questions from this chapter's territory, with their board of origin. No catalogued theory question falls inside the disruptive behaviour and conduct disorders, the childhood emotional disorders, the attachment disorders, the tic disorders or the elimination and feeding disorders in the examined window held in the intel index, so none is printed here. No question is reconstructed, paraphrased into a new one, or invented to pad the list. That a topic has not been asked as a set-piece essay does not lower its yield: conduct disorder against oppositional defiant disorder and disruptive mood dysregulation, the callous-unemotional specifier, tic pharmacotherapy scoped to its indication, the imipramine enuresis dose and its cardiotoxicity, and the attachment-disorder differential from autism are all live short-note and viva territory, and the chapter is built to answer them.

TRAP **An unasked topic is not a low-yield topic.** The absence of a past essay is a fact about one board's recent papers, not about what an examiner may ask this year. Prepare the discriminations and the doses, not the past paper.

The quick review

One table, read down the left column, cover the right. Every line is taught in full somewhere above; nothing here is new. Where the sources disagree, the disagreement is the answer.

ASK	HOLD
WHAT DSM-5 REQUIRES FOR CONDUCT DISORDER	A repetitive pattern violating the basic rights of others or major age-appropriate norms, drawn from four clusters: aggression to people and animals, destruction of property, deceitfulness or theft, and serious rule violations. At least three of the fifteen criteria in the past year, at least one in the past six months. The clusters and the count are the marks.
THE TWO ONSET SUBTYPES AND WHY THEY MATTER	Childhood-onset (at least one symptom before age ten) carries the worse prognosis, more aggression and the stronger link to antisocial personality disorder; adolescent-onset is more normative in its peer context and remits more often. The subtype is a prognostic statement.
THE LIMITED-PROSOCIAL-EMOTIONS SPECIFIER	The callous-unemotional phenotype, applied when at least two of four features persist over twelve months across relationships and settings: lack of remorse or guilt, callous lack of empathy, unconcern about performance, and shallow or deficient affect. It marks a distinct developmental pathway, not merely severe conduct disorder.

ASK	HOLD
CONDUCT DISORDER AGAINST OPPOSITIONAL DEFIANT DISORDER	ODD is angry and irritable mood, argumentative and defiant behaviour, and vindictiveness, without the aggression to people and animals, destruction, theft and serious rights-violation of conduct disorder. ODD can precede conduct disorder; it is not a milder synonym for it.
PHARMACOTHERAPY OF AGGRESSION IN CONDUCT DISORDER	Psychosocial treatment is first-line: parent management training for younger children, multisystemic therapy for adolescents. Medication (risperidone the best evidenced) is an adjunct for serious aggression only, scoped to that indication. It is not a conduct-disorder cure and it is not automatically disruptive-mood-dysregulation-disorder evidence.
WHAT DSM-5 REQUIRES FOR DMDD	Severe recurrent temper outbursts out of proportion to provocation, on average three or more times a week, with persistently irritable or angry mood between outbursts, for twelve months across at least two settings, onset before age ten, diagnosed between ages six and eighteen. It is a depressive-spectrum disorder.
DMDD AGAINST PAEDIATRIC BIPOLAR DISORDER	DMDD is chronic, non-episodic irritability; paediatric bipolar is episodic mania, discrete periods of elevated or expansive mood with the syndrome change. Blurring the episodic-versus-chronic line is the error; DMDD was created precisely to catch the chronically irritable child who was being over-diagnosed as bipolar.
SOMATIC PRESENTATION AGAINST SOMATIC SYMPTOM DISORDER	Recurrent abdominal pain and headaches are how childhood anxiety and depression often present, a somatisation of distress. Somatic symptom disorder proper does NOT require the symptom to be medically unexplained; conversion, now functional neurological symptom disorder, is a distinct entity and is not reducible to mood somatisation.
SEPARATION ANXIETY AGAINST NORMAL DISTRESS	Developmental separation distress peaks in the toddler years and settles; the disorder is developmentally excessive fear of separation, persistent for at least four weeks in a child, with impairment. School refusal is anxious non-attendance with the child at home and the parents aware, distinct from concealed truancy.
PAEDIATRIC OCD AND PANDAS	PANDAS and the broader PANS are a CONTESTED hypothesis of abrupt-onset OCD or tics after streptococcal or other infection, not settled causation. Teach the definition and the controversy; presenting the streptococcal link as an established cause is the error.
THE YOUTH ANTIDEPRESSANT WARNING	An SSRI, usually fluoxetine, is the first-line medication for moderate to severe childhood depression, alongside psychotherapy. The boxed warning reflects a small increase in suicidal ideation and behaviour in the pooled paediatric trials, roughly four percent against two percent on placebo, with no completed suicides. The answer is to monitor closely early, not to withhold treatment.

ASK	HOLD
REACTIVE ATTACHMENT AGAINST DISINHIBITED SOCIAL ENGAGEMENT DISORDER	Both require a history of pathogenic care. Reactive attachment disorder is the emotionally withdrawn, inhibited child who does not seek comfort; disinhibited social engagement disorder is the indiscriminately sociable child who wanders off with an unfamiliar adult. Two patterns, one adverse-care root.
ATTACHMENT DISORDERS AGAINST AUTISM	The attachment-side view: a history of pathogenic care and clear improvement with a stable, sensitive caregiver point to attachment disorder, whereas the pervasive social-communication deficit and the restricted and repetitive behaviours of autism persist across environments. Autism itself is the intellectual disability and autism spectrum disorder notes' to teach.
WHAT DSM-5 REQUIRES FOR TOURETTE SYNDROME	Both multiple motor tics and at least one vocal tic at some time, not necessarily concurrently, present for more than one year, with onset before age eighteen. The premonitory urge and the waxing-and-waning course are the phenomenology; comorbid ADHD and OCD drive most of the impairment.
TIC PHARMACOTHERAPY, SCOPED TO THE INDICATION	Behavioural treatment first: habit reversal training within comprehensive behavioural intervention for tics. Then the alpha-2 agonists guanfacine and clonidine, and the antipsychotics aripiprazole, risperidone and the classical agents, each at its TIC dose. The tic-indication dose is not the ADHD-indication alpha-2 dose and not the autism-indication antipsychotic dose; every dose carries its indication.
TIC AGAINST STEREOTYPY, CHOREA AND DYSTONIA	Tics are sudden, non-rhythmic, involuntary and briefly suppressible with a premonitory urge; stereotypies are rhythmic, fixed, soothing and present from earlier; chorea is flowing and unpredictable; dystonia is sustained and twisting. The premonitory urge and the suppressibility mark the tic.
ENURESIS MANAGEMENT AND THE IMIPRAMINE TRAP	Behavioural measures and the bell-and-pad alarm are the durable first line; desmopressin is the most-used drug, oral preferred over intranasal for the hyponatraemia risk. Imipramine is reserved for refractory cases: the paediatric enuresis dose is tens of milligrams total at bedtime (around 50 mg for ages six to twelve, 75 mg over twelve), NOT a large per-kilogram figure, and its cardiotoxicity and overdose lethality are the reason the dose and the electrocardiogram matter.
ARFID AGAINST THE EATING DISORDERS	Avoidant restrictive food intake disorder is a failure to meet nutritional needs from restricted intake WITHOUT the body-image disturbance or the drive for thinness of anorexia and bulimia. Anorexia and bulimia are the eating and sleep-wake disorders notes'; ARFID is named and distinguished here, not taught there.

ASK	HOLD
ENCOPRESIS	Repeated passage of faeces into inappropriate places from age four, most often retentive with overflow soiling on a background of constipation; management is disimpaction, then maintenance laxatives and a scheduled toileting programme, not primarily a psychiatric drug.
JUVENILE DELINQUENCY	A legal and social construct, not a DSM or ICD diagnosis. The psychiatric task is to assess for the conduct disorder, ADHD, substance use and mood or trauma that often underlie it; the juvenile-justice framework is named and cross-referred to the child psychiatry: assessment, treatment, services and protection notes, and any statutory specific is read from the primary Act, not asserted here.
WHAT THE SOURCES REFUSE TO TELL YOU	Several India-specific prevalence figures for these disorders, the exact standardised scoring bands of some rating scales, and the precise upper age of the extended antidepressant warning are not settled in the literature consulted. The chapter says so where it happens rather than inventing them.

References

Every specific in this chapter is bound to one of the sources below, and the count is the number of claims each carried. Books and guidelines are cited author, title and year in the house convention; no PMID is asserted for a book. For every diagnostic criteria set the primary manual (DSM-5-TR 2022 and ICD-11 CDDR) is the authority, not a textbook paraphrase. This chapter touches no statute it reproduces: item 88 names the juvenile-justice framework and cross-refers rather than stating any Juvenile Justice Act specific. 9 claims are recorded at partial confidence (an honest open gap or a figure to confirm against a primary source at review), never an invented number. The must-have-papers cross-check was NOT performed for this Paper III chapter, because the paper lists do not yet exist in the intel index; for Paper III the topic bank plus the syllabus scaffolding is the completeness authority.

PAPER III

Child psychiatry: assessment, treatment, services and protection

Seven bands . one complete notes document

Orientation: the system around the child

1 · Orientation: the system around the child

Why this chapter matters clinically. A child does not arrive as a diagnosis detached from the people, settings and developmental tasks that give symptoms their meaning. The psychiatrist meets a young person whose distress is expressed through behaviour, feeling, body, learning, relationships and participation. The clinical task is therefore to understand the child as a **whole child**, then to make care workable for the family, school and wider systems around that child.

This is an **advance organizer** for a chapter about that surrounding system. It is not a catalogue of childhood disorders. The disorders themselves, including the **internalising and externalising axis** that organises them, are taught in *the Child behavioural, emotional and other disorders notes*. Intellectual disability and autism spectrum disorder are addressed in *the Intellectual disability and autism spectrum disorder notes*; normal temperament, developmental norms and milestones are addressed in *the Normal child development and milestones notes*. Here, the emphasis is on what the clinician does once a child needs psychiatric help: understand, plan, intervene, connect and protect.

WHOLE	CLINICAL	SHARED	SAFE
CHILD	PLAN	SUPPORT	CARE

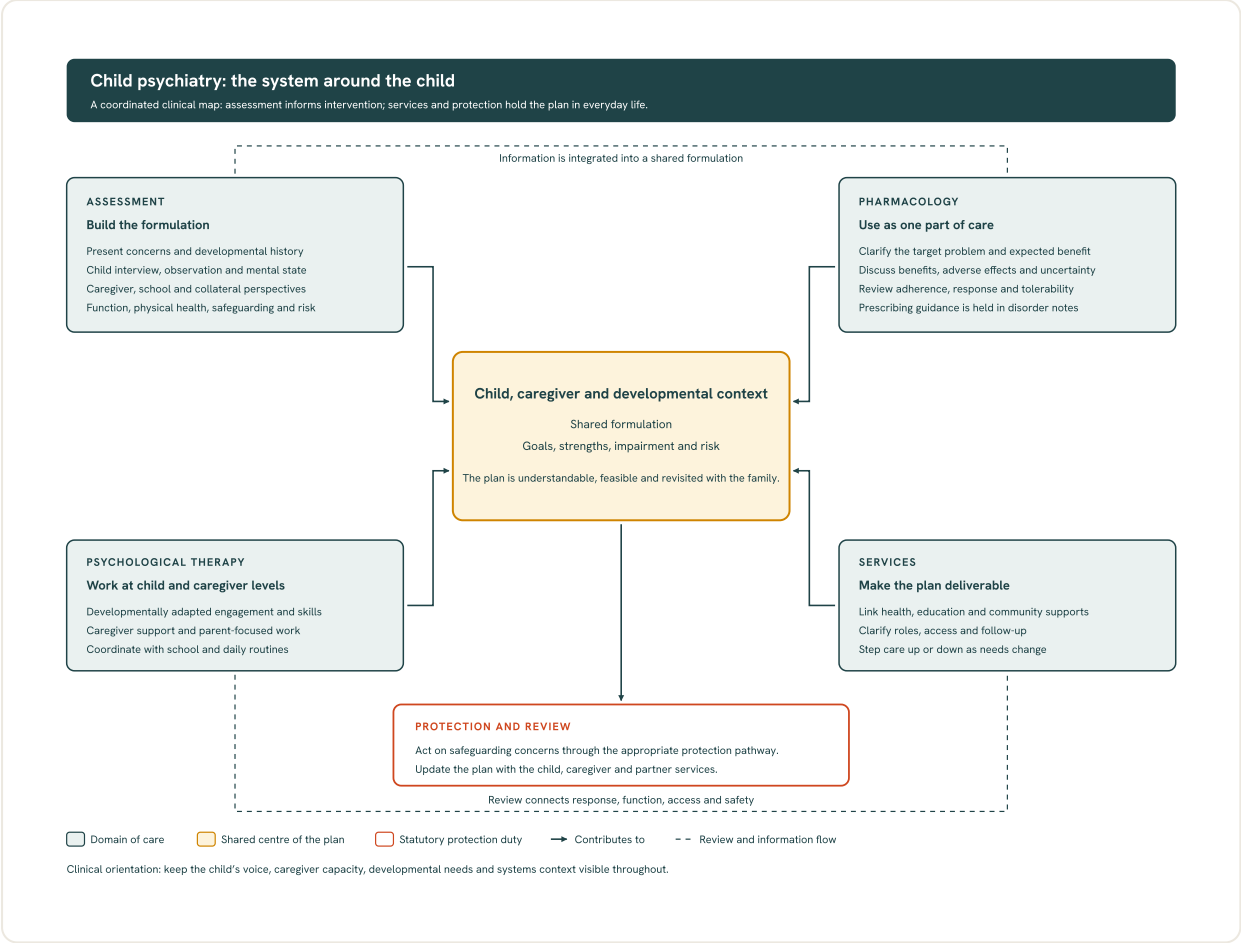

Fig 24.1. The system around the child: how assessment, prescribing, psychological and educational treatment, the Indian service platforms and the statutory protection framework connect for one child. Read it as the chapter's route map rather than as a sequence, since a real case moves between these domains repeatedly.

1.1 The clinical frame: child, context and consequence

Child psychiatry starts with a developmental question: what is happening to this child, in this context, and with what consequences for everyday life? A symptom can alter school participation, peer belonging, family routines and confidence; each of those consequences can in turn maintain distress or restrict recovery. The chapter therefore treats clinical work as a **system around the child**, rather than as a sequence of isolated consultations.

This frame protects against a familiar reductionism. A diagnostic label may guide treatment, but it cannot by itself tell the clinician what a child understands, what a caregiver can implement, what the school observes, or whether the child is safe. Nor should a child be reduced to a family problem, a school problem or a medicine problem. The useful question is always practical as well as descriptive: what would change the child's ability to develop, participate and feel secure?

RULE **Think of the child and the care environment together.** Symptoms are assessed in the child, but intervention succeeds or fails in the relationships and settings in which daily life takes place.

The accompanying figure can be used as a visual reminder of this clinical map. It should not be read as a rigid pathway. A family may enter through a school concern, a behavioural crisis, a developmental worry, a medical referral or a disclosure of harm. The psychiatrist's work is to

organise the response without losing the child's voice or the actual conditions in which care must happen.

1.2 Assessment: turning concern into an intelligible formulation

Assessment is the chapter's starting movement because treatment without a clear understanding is merely activity. The assessment sections show how history, examination, developmental perspective, observation, play, structured measures and cognitive or neuropsychological methods can contribute to an account of the child's needs. They also show why evidence from the child, caregivers, school and other relevant adults may differ without any one informant being simply wrong.

The point is not to collect every possible datum. It is to build a **working formulation** that explains the presenting concern in developmental and relational context, identifies functional impact, and clarifies what must be addressed first. Assessment should generate decisions: whether a further evaluation is needed, who needs to be involved, which supports are realistic, and whether there is a safety concern that changes the pace or setting of care.

- Listen for the child's experience and language, not only the adult account of behaviour.
- Place the concern within development, relationships, education and health.
- Use each assessment method for the question it can answer, rather than treating an instrument as a diagnosis.
- Translate findings into a plan that family and school can understand.

> **GOOD TO REMEMBER**
>
> A careful assessment is already an intervention when it helps adults replace blame with curiosity and gives the child an experience of being heard accurately.

TRAP **Do not confuse a list of findings with a formulation.** Candidates often describe history, tests and ratings well but fail to state how those findings explain the child's current difficulty or alter the management plan.

1.3 Prescribing: medication as one part of accountable care

When medication is considered, the question is not simply whether a drug can reduce a symptom. The psychiatrist must decide whether pharmacological treatment has a clear target within the child's overall plan, whether its likely benefits matter to the child's daily functioning, and how effects will be understood alongside changes at home and school. The prescribing sections address developmental pharmacology, medication classes, cautious use, monitoring, consent and review.

The chapter asks the reader to retain a **prescribing rationale** rather than a prescription habit. A rationale makes explicit what is being treated, how benefit will be recognised, what unwanted effects require attention, and how the family will participate in observation and decision-making. It also keeps medication from displacing educational, psychological, family or safeguarding work when those are the interventions that matter most.

For disorder-specific pharmacological treatment, cross-refer to *the ADHD and specific learning/communication disorders notes*, *the Child behavioural, emotional and other disorders notes*, and *the Intellectual disability and autism spectrum disorder notes*. The present chapter supplies the clinical discipline around prescribing, not a disorder-based regimen.

PITFALL

Improvement in a narrow symptom is not automatically improvement in the child's life. Review must return to function, participation, relationships and the family's capacity to sustain the plan.

1.4 Psychological, family and educational treatment

Psychological treatment in child psychiatry is not an optional conversation added after diagnosis. It is a set of developmentally adapted ways of changing patterns of emotion, behaviour, relationship and learning. The treatment sections cover play-based work, behavioural approaches, parent work, family interventions, cognitive behavioural approaches, special education, remedial measures and early developmental support. Their common thread is that the intervention must fit the child's developmental capacities and the adults who carry much of the treatment between sessions.

The key unit of care is often the **shared plan**: a plan that gives the child a comprehensible role, gives caregivers achievable tasks, and makes space for school or other supports when relevant. This is not a dilution of clinical responsibility. It is how a treatment becomes visible in ordinary life. The psychiatrist remains responsible for coherent formulation, appropriate referral, review and revision when the plan does not fit.

CLINICAL MOVEMENT	QUESTION FOR THE PSYCHIATRIST	PURPOSE WITHIN CARE
Assessment	What is happening, for whom, and in which context?	Make the problem intelligible.
Prescribing	Is medication justified within a broader plan?	Use pharmacology accountably.
Psychological and educational treatment	What change can the child and adults practise in daily life?	Build skills and support participation.
Services	Which setting can sustain the work?	Connect care beyond the clinic.
Protection	Is there harm, risk or a legal duty that changes the response?	Place safety before routine.

1.5 Services in India: making care reachable and continuous

A treatment recommendation has little value if it cannot be reached, understood or sustained. Child mental health care therefore includes the practical work of locating the child within a **continuum of care**: family, school, health services, developmental and educational supports, and community resources. The services sections describe Indian child-health and school-facing platforms, their purposes and how they can complement specialist psychiatric care.

For the psychiatrist, services are not background administration. They determine whether a child is identified early, whether caregivers receive help outside the consultation room, whether educational needs are addressed, and whether follow-up survives distance, cost and competing family demands. Referral is most useful when it is specific about the problem to be addressed and when responsibility for clinical review remains clear.

IN INDIA

The service discussion is deliberately grounded in Indian pathways. Learn to recognise what a school, child-development platform, health service and specialist team can each contribute, then connect them around the child rather than treating referral as a hand-off.

- Ask what support already exists in the child's ordinary environment.
- Specify the purpose of every referral, the information that should travel with it, and barriers that can interrupt follow-up or implementation.

1.6 Protection: safety is a clinical responsibility

Protection enters every child psychiatric assessment because distress may occur alongside abuse, neglect, exploitation, bullying, family violence or other threats to safety. The protection sections distinguish forms of harm, clinical indicators, assessment after sexual abuse, statutory duties, management, juvenile justice and related psychiatric concerns. Their purpose is to help the clinician recognise when ordinary therapeutic pacing is no longer adequate.

Safeguarding requires a **protective response**: attention to the child's immediate safety, accurate documentation, appropriate communication, lawful reporting and connection with the relevant protection system. It is neither an accusation nor a private clinical matter that can be indefinitely deferred while certainty is sought. At the same time, it requires restraint, careful language and respect for the child's dignity. The legal and procedural details belong to the dedicated protection sections and to *the Mental health legislation and forensic psychiatry notes* for general criminal responsibility, mental-health legislation and adult forensic assessment.

MNEMONIC

MAPS: Meet, Assess, Plan, Support, Safeguard

Use this master mnemonic to retain the chapter's clinical route. Meet the child as a person in context; assess before acting; plan medication and psychological care deliberately; support the family and service network; safeguard whenever safety or legal duty enters the case.

The child is never only the diagnosis: assessment, treatment, services and protection must be organised around the child's lived developmental world.

Child psychopharmacology

2 · Principles of prescribing psychotropics in children

Why it matters clinically. Prescribing for a child is not a smaller version of prescribing for an adult. The prescription enters a developing person, a family system, a school context and a network of carers. Its quality is therefore judged not merely by the medicine selected, but by whether the clinician has defined the problem, made the treatment purpose intelligible, anticipated practical obstacles and retained responsibility for review.

Psychotropic medication can reduce suffering and improve a child's capacity to participate in home, school, relationships and psychological treatment. It can also obscure an unclear formulation, displace environmental work, or become a source of conflict if introduced without shared understanding. The central task is disciplined clinical reasoning: prescribe when a medicine has a plausible, proportionate role in a broader plan, and make that role visible to the child and family.

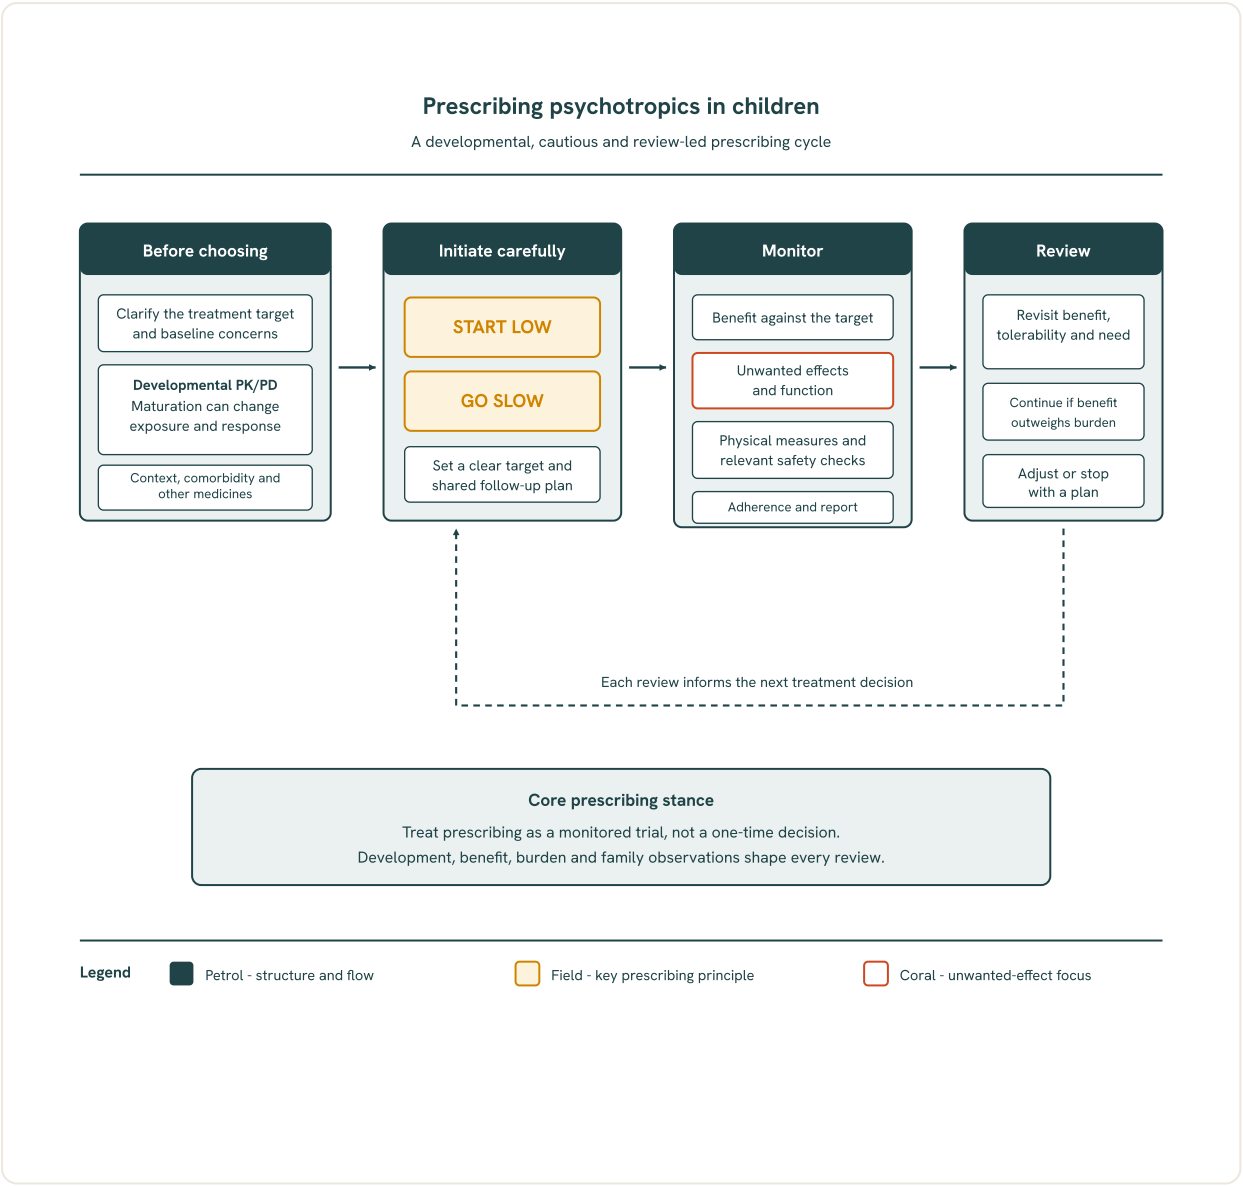

Fig 24.2. A child psychotropic prescription is a developmental, cautious and monitored trial: start low, go slow, assess benefit and burden, and use planned review to guide the next decision.

2.1 The prescribing question

A sound prescription begins with a **treatment target**. This is the concrete difficulty that the medicine is intended to change, described in observable clinical language and linked to impairment. “Behaviour problems” is not a treatment target. Nor is a diagnostic label, by itself, a sufficient instruction to prescribe. The clinician should be able to state what is happening, where it happens, what maintains it, how it affects the child, and what change would count as benefit.

That discipline protects against diagnostic momentum. A child may present with distress, disruptive conduct, sleep disruption, poor concentration, somatic complaints or emotional withdrawal. These phenomena can arise from psychiatric illness, developmental differences, trauma, family stress, learning difficulty, physical illness, substance exposure, medication effects or an interaction among these. Medication may be appropriate, but only after the presenting problem has been placed in a developmental and psychosocial formulation. The prescription should answer a clinical question rather than substitute for one.

RULE **Prescribe for a defined problem within a formulation, not for a label or for pressure to act.** A medication decision should follow a clear account of symptoms, impairment, context and the intended place of pharmacotherapy in the care plan.

Severity matters in a functional sense. The same symptom can carry very different implications depending on its persistence, setting, consequences and the child's available supports. A clinician should ask whether the intervention is intended to relieve acute suffering, reduce risk, enable engagement with other treatment, restore daily functioning, or prevent a pattern from becoming entrenched. Stating the purpose also makes later review possible: benefit is judged against the original target rather than against a vague impression that the child is "better".

- Describe the target problem in language the family can recognise.
- Identify the impairment or risk that gives the target clinical importance.
- Specify what non-medication interventions are active, planned or unavailable.
- Decide what observable change would justify continuing treatment.

2.2 Developmental formulation before pharmacotherapy

Developmental formulation means interpreting symptoms in relation to the child's developmental level, communication capacity, temperament, family relationships, educational demands and medical context. It is not a decorative paragraph added after diagnosis. It determines whether the reported difficulty is best understood as illness, an unmet developmental need, a mismatch between demands and capacity, a response to adversity, or a mixture of these.

The child's own account deserves deliberate effort, even when language, cognition, fear or loyalty to adults limits direct disclosure. Behaviour is often communication. Irritability may express distress, sensory overload, grief, pain, humiliation, anxiety or a coercive family pattern. Apparent non-adherence may reflect swallowing difficulty, unpleasant effects, stigma, a child's wish to retain control, or a caregiver's uncertainty. These meanings do not rule out medication; they determine whether medication is likely to help and how it should be offered.

Collateral information is essential, but it must be interpreted rather than collected mechanically. Different observers see different settings and bring different expectations. Disagreement between home and school accounts may identify environmental triggers, differences in structure, divergent relationships or a problem that is context-bound. It should not automatically be treated as evidence that one informant is unreliable. General child psychiatric assessment is addressed in the assessment section of this chapter; prescribing should use that formulation rather than recreate an abbreviated assessment in the prescription note.

CLINICAL QUESTION	WHY IT CHANGES PRESCRIBING	USEFUL CONSEQUENCE
What is the child experiencing?	Symptoms and their meaning may differ from adult descriptions.	Use developmentally understandable targets and explanations.
Where does the problem occur?	Context can reveal triggers, supports and limits of a medicine-only plan.	Link prescribing to home and educational interventions.
What else could account for it?	Medical, developmental and psychosocial contributors can alter the clinical question.	Address contributors rather than escalating medication reflexively.
What can the child and caregivers realistically do?	A technically sound regimen fails if it cannot be followed or understood.	Choose a plan that fits daily life and review its feasibility.

TRAP **Do not mistake a symptom description for a completed formulation.** A striking symptom can create urgency, but urgency does not remove the need to ask what the behaviour means, what context is sustaining it, and what the medicine can realistically change.

2.3 Proportionality and the place of medication

Proportionality is the fit between the expected benefit of medication and the burden, uncertainty and alternatives in the particular child. It asks more than whether a medicine can work. It asks whether it is the right next intervention, whether the expected gain matters to this child's life, and whether the family understands the trade-off. A medicine is not made benign by familiarity, and a psychosocial intervention is not made adequate merely by being recommended.

Psychological therapy, parent work, educational support, environmental adaptation and treatment of coexisting medical problems are not competitors to pharmacotherapy. Often they provide the conditions in which a medicine can be useful. A severely distressed child may be unable to use therapy until symptoms ease; equally, medication may have little effect on a coercive interaction pattern, an unsafe environment, educational mismatch or lack of routine. The plan should make clear which intervention is addressing which part of the formulation.

Polypharmacy requires particular restraint. When several changes are made at once, the clinician loses the ability to know what produced benefit, what caused harm, and what is no longer necessary. Additional medicines can also conceal inadequate adherence, an incorrect target, a missed contributor or a fragmented service pathway. There are circumstances in which combined treatment is clinically justified, but it should be deliberate, documented and owned by a clinician who can review the whole regimen.

- Ask what the medicine is expected to add to the existing plan.
- Ask what important part of the formulation the medicine cannot address.
- Prefer a plan whose effects can be interpreted clinically.
- Reconsider medication when the original target no longer justifies its burden.

GOOD TO REMEMBER

A clear prescription note links the medicine to a target, the target to impairment, and the medicine to the rest of the care plan. This protects continuity when care moves between clinicians or settings.

2.4 Partnership with the child and caregivers

Shared decision-making is a clinical method, not a formality. It means presenting the treatment purpose, anticipated benefits, important uncertainties, likely burdens and practical demands in a way that the family can use. The child should be included to the extent possible. Inclusion does not mean assigning adult responsibility to a child; it means taking seriously what the child notices, fears, values and can participate in.

Caregivers need a practical account of what the medicine is and is not intended to do. They should know which changes to observe, how to communicate concerns, and why independent changes in administration can make assessment difficult. Questions about dependence, personality change, long-term effects and stigma should be invited rather than dismissed. A family that feels corrected or rushed may agree in the room yet alter the plan outside it. Honest discussion is more likely to produce a usable treatment alliance.

Family disagreement is common and should be explored rather than reduced to "non-compliance". One caregiver may see suffering while another fears labelling; a school may seek rapid behavioural change while the child experiences the medicine differently. The prescriber's role is to restore the clinical question, distinguish values from misinformation, and avoid allowing the prescription to become a proxy battle over blame or control. Formal issues of parental permission, child assent, capacity and documentation belong to the chapter section on monitoring and consent issues in child psychopharmacology.

IN INDIA

Care is often distributed across parents, grandparents, schools and more than one medical service. Ask who actually gives the medicine, who can report change, who pays for follow-up and who may discontinue treatment if adverse effects or stigma are feared. A plan built around the person present in the clinic may fail in the household where it must operate.

2.5 Communicating a plan that can be followed

Adherence is better understood as the degree to which a treatment plan is feasible, acceptable and sustained than as an attribute of a "good" family. It can be undermined by complicated routines, cost, inconsistent supervision, formulation or swallowing difficulties, adverse experiences, poor understanding, stigma and competing household demands. Asking a neutral question such as "What might make this difficult at home?" is usually more informative than asking whether the medicine is being taken.

Written instructions should complement, not replace, conversation. Avoid unexplained abbreviations and make the plan legible to the person who will implement it. Clarify the target, the expected course of review, what observations matter, and what should prompt contact with

the treating team. Medication storage and access require attention wherever there are younger children, family members at risk of self-harm, or a possibility that a medicine may be shared, diverted or used in an unintended way.

Communication with school can be valuable when the educational setting is central to impairment or observation. It should be purposeful and proportionate. The school needs only the information required to support the child and report relevant change; it does not need a full psychiatric narrative. Protecting confidentiality is especially important when medication itself risks becoming a source of labelling or peer attention.

PITFALL

Do not treat a family's difficulty following a regimen as proof that they are careless or oppositional. First examine whether the plan is understandable, affordable, acceptable and compatible with the actual caregiving arrangement.

2.6 Review as a continuing clinical decision

Medication review is the process of returning to the original treatment target and deciding, with fresh information, whether the medicine still has a proportionate role. It is not merely a request for a repeat prescription. The reviewer should ask about meaningful change in the child's life, unwanted effects, the family's experience of administering treatment, changes in context, new symptoms, concurrent medicines and whether the original formulation still explains the problem.

Review is where diagnostic humility becomes visible. Lack of benefit may mean that the target was wrong, the medicine is not useful for that target, the plan was not practicable, a psychosocial driver remains dominant, or the observations are incomplete. The response should not automatically be escalation. Conversely, apparent improvement should not automatically be attributed to medication when school support, family change, maturation, therapy or the natural course may have altered the picture. Attribution is often provisional, which is why a documented baseline and a shared account of the target are so valuable.

Prescribing continuity needs named responsibility. Children may move between outpatient care, emergency services, paediatric specialties, schools or residential settings. At each transition, someone should reconcile the current plan, clarify who is reviewing it, and ensure that old instructions do not persist by inertia. The detailed framework for baseline assessment, safety surveillance, consent and the timing of review belongs to the chapter section on monitoring and consent issues in child psychopharmacology.

Target	Context	Family	Plan
DEFINED	FORMULATED	PARTNERED	REVIEWED

2.7 Boundaries of the general framework

This general framework should not be used to improvise drug-specific practice. Developmental pharmacokinetics and pharmacodynamics are addressed separately. Medication-specific

indications, adverse-effect issues and monitoring requirements belong to the relevant drug sections. Stimulant treatment is cross-referred to *the ADHD and specific learning/communication disorders notes*. Childhood disorders and the paediatric SSRI black-box warning are cross-referred to *the Child behavioural, emotional and other disorders notes*. Intellectual disability and autism spectrum disorder are cross-referred to *the Intellectual disability and autism spectrum disorder notes*.

The realities of off-label prescribing, dose selection and cautious titration belong to the section on off-label prescribing, dosing principles and start-low go-slow in children. This separation matters. A general principle can tell the clinician how to think about a prescription; it cannot safely replace the evidence, indication-specific reasoning or monitoring requirements for a particular medicine.

MNEMONIC

TARGET

Target the problem; **A**ssess its developmental and contextual meaning; **R**elate medication to the wider plan; **G**ive the child and caregivers a real voice; **E**xamine feasibility; **T**rack benefit and burden; retain clear clinical responsibility. It is a thinking aid, not a substitute for drug-specific guidance.

A child psychotropic prescription is justified by a clear target, a developmental formulation, a proportionate place in the plan and an accountable review process.

3 · Developmental pharmacokinetics and pharmacodynamics in children

Why it matters clinically. A child is not a smaller adult with a smaller tablet. Development changes the processes that carry a medicine from administration to the circulation, through the body, and out again. The practical consequence is not simply that a prescriber calculates a smaller amount. It is that the relation between an administered amount, the concentration that results, and the clinical effect must be interpreted through the child's developmental state. This is the pharmacological reasoning that sits beneath safe individualisation of treatment.

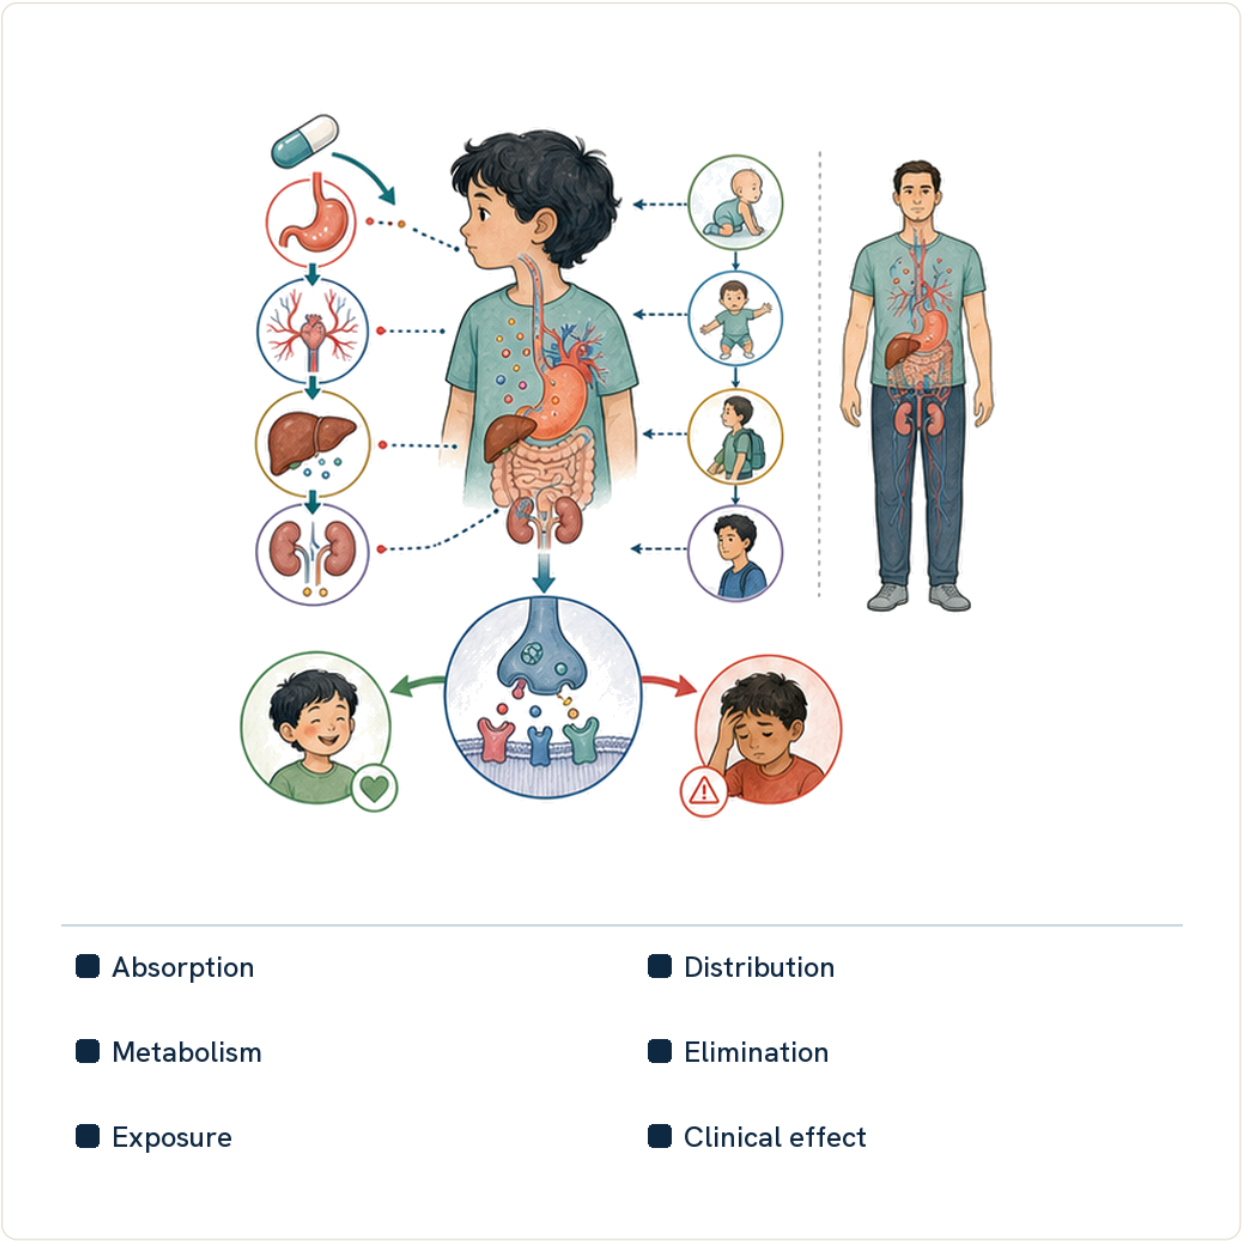

Fig 24.3 Development changes drug absorption, distribution, metabolism and elimination, altering the exposure produced by a dose. Pharmacodynamics then links that exposure to intended and unintended effects; weight-based calculation alone does not complete the reasoning.

Developmental pharmacology has two linked questions. Pharmacokinetics asks what the body does to a medicine: how much reaches the circulation, how it is distributed, transformed, and eliminated. Pharmacodynamics asks what the medicine does at its site of action: how exposure is translated into intended and unintended effects. Neither question supplies a regimen by itself. The general prescribing framework, consent and review processes are addressed elsewhere in this chapter; here the task is to understand why a concentration or a weight-based calculation cannot be read in isolation.

AGE	METABOLISM	BINDING	CLEARANCE
CHANGES DRUG HANDLING	CAN ALTER EXPOSURE	SHAPES LEVEL INTERPRETATION	GUIDES DOSE SCALING

3.1 The developmental frame

Developmental pharmacokinetics is the study of changing drug handling across childhood. Its central clinical value is explanatory. If a medicine produces an unexpected concentration, inadequate benefit, or unwanted effect, the question is not only whether the stated amount was taken. One must also ask whether the child's current physiology changes exposure at an earlier or later part of the pathway. A result that appears anomalous when compared with an adult expectation may be coherent once developmental handling is considered.

This is especially important because childhood is not pharmacologically uniform. Development proceeds along several biological processes that need not move together. A change in one process can alter the meaning of a change in another. Thus, an administered amount is only the beginning of a causal chain. What matters clinically is the exposure eventually available to exert an effect, and the child-specific processes that shape it. This reasoning protects against the easy but unsafe assumption that body size alone completely predicts drug behaviour.

The useful mental model is a pathway rather than a single number:

- the medicine reaches the body and may undergo loss before entering the systemic circulation;
- circulating medicine is present in bound and unbound forms;
- metabolic and renal processes remove parent drug or metabolites; and
- the concentration at the relevant site is interpreted alongside the observed clinical response.

RULE **In children, an administered amount is not a direct measure of exposure.** Developmental physiology lies between the prescription and the concentration that is ultimately available to act.

For the candidate, this is not an invitation to memorise isolated developmental facts. It is a way of explaining clinical variability without collapsing it into adherence, diagnostic error, or presumed treatment resistance. It also clarifies why a prescription should be revisited whenever the child's developmental context or intercurrent illness changes the likely relation between amount and exposure.

3.2 Metabolism, bioavailability and elimination

Drug metabolism is a major source of developmental variation. The capacity to transform a medicine depends on developmental changes in metabolising systems. These changes can alter both **bioavailability** and **elimination**. In other words, metabolism can influence how much medicine enters the circulation as well as how long medicine already in the circulation remains there. This is why metabolism should not be treated as a late, purely eliminative event.

The clinical implication is that the principal metabolic route and the rate at which metabolites form may differ from adult patterns and may also differ among paediatric developmental groups. A medicine can therefore have a different exposure profile in a child even when the arithmetic looks proportional to body weight. The relevant question is not whether a calculation is mathematically tidy, but whether it represents the child's likely route of handling the medicine.

Metabolism also complicates simple interpretations of effect. The parent medicine and its metabolites may not contribute to the clinical picture in the same way. If developmental metabolism changes their relative formation, the observed response may not track an adult expectation based only on the parent compound. At textbook level, the key point is conceptual: an apparent mismatch between amount and response may arise before the medicine reaches its intended site, during its transformation, or during its removal.

GOOD TO REMEMBER

A developmental explanation is most useful when it specifies the link in the chain that may have changed. "Children metabolise medicines differently" is too vague. Ask whether developmental metabolism is plausibly changing entry into the circulation, removal from it, or the relative contribution of metabolites.

This helps separate pharmacokinetic reasoning from a medication "rule." There is no universal developmental direction that can be applied indiscriminately across medicines. The useful inference is conditional: when intestinal or hepatic metabolic processes materially contribute to a medicine's handling, developmental changes in those processes can change exposure. The prescriber must then use drug-specific information and the full clinical context, rather than treating an adult amount as a template that can simply be reduced.

3.3 Protein binding and the meaning of a blood level

A measured concentration is often treated as if it were the clinical answer. It is not. **Protein binding** can change with developmental age and with concomitant illness. This matters because the measured level usually represents circulating drug in a sample, whereas pharmacological action depends on the drug available to leave the circulation and reach its site of action. The interpretation of a reported level therefore requires attention to the binding context, not merely to whether the result lies on one side of a reference interval.

The clinically relevant idea is the **free drug fraction**. When binding differs, the relationship between total measured drug and pharmacologically available drug may also differ. This does not mean that a total level is useless. It means that the level is a piece of evidence whose meaning depends on the child's physiology, illness, sampling circumstances and clinical state. A result should be integrated with the observed response and adverse effects, not made to overrule them automatically.

QUESTION	DEVELOPMENTAL PHARMACOKINETIC INTERPRETATION	CLINICAL REASONING CONSEQUENCE
What does a blood level represent?	A circulating measurement influenced by age and illness-related binding.	Interpret the result in its physiological context.
Why can a familiar value mislead?	The relation between total concentration and available drug may not be constant.	Do not let the number substitute for clinical assessment.
What should a dose adjustment address?	The likely exposure problem, not an isolated laboratory value.	Link the decision to response, tolerability and the child's current context.

Concomitant illness deserves particular attention because it can change binding at the same time as it changes the child's clinical presentation. It is therefore easy to attribute new symptoms either wholly to illness or wholly to medication. Pharmacokinetic thinking holds both possibilities open. It asks whether the illness may change the relation between a measured total level and the active exposure, while clinical assessment determines whether the observed symptoms fit that explanation.

TRAP **A total blood concentration is not automatically a direct measure of active exposure.** Ignoring developmental or illness-related binding turns a useful measurement into a falsely decisive one.

3.4 Clearance as the bridge from physiology to dose

Clearance is the most useful organising parameter for relating age and body weight to paediatric dose. It describes the body's capacity to remove a medicine from the circulation. Because clearance changes the exposure that follows an administered amount, it provides a rational bridge between physiology and dose scaling. Scaling clearance from one paediatric age group to another is a commonly used approach, but it is not a permission slip for uncritical extrapolation from adults.

The distinction matters. Body weight is clinically valuable, but it does not itself describe every developmental process that determines clearance. The same body-size calculation may conceal different contributions from metabolism, filtration, secretion and illness. Clearance-based reasoning asks what removal processes are important for the medicine in question and whether those processes are likely to be developmentally different in the child being treated. The answer can then inform the use of drug-specific dosing information.

Renal clearance is an important example. Glomerular filtration continues to increase until **approximately one to two years of age**, after which it begins to decline toward adult levels. Active tubular secretion follows a similar early trajectory until **two years of age** and then gradually increases into adulthood. For medicines substantially removed through the kidney, this changing physiology makes a fixed assumption about removal particularly unreliable in early childhood.

The point is not to convert a developmental timeline into a universal dose formula. The point is to recognise why renal handling must be part of the explanation when a renally eliminated medicine behaves unexpectedly. Both filtration and secretion belong in the conceptual map. A prescriber who thinks only of filtration may overlook another active component of renal drug removal; a prescriber who thinks only in kilograms may overlook why age-specific drug information remains necessary.

PITFALL

Do not use a general statement about renal maturation as though it determines the regimen for every medicine. Its relevance depends on how much the particular medicine and its metabolites rely on renal removal. The developmental principle guides interpretation; drug-specific information guides the actual prescription.

3.5 Developmental pharmacodynamics

Pharmacodynamics concerns the relation between exposure at the site of action and the resulting therapeutic or adverse effect. Developmental pharmacodynamics asks whether that relation may differ as the child develops. It is conceptually distinct from pharmacokinetics. A pharmacokinetic difference changes the concentration achieved. A pharmacodynamic difference changes the meaning of a given concentration for effect. In practice the two are often hard to disentangle, which is why an observed response should not be used to make a simplistic inference about either process alone.

For psychiatric prescribing, pharmacodynamic reasoning has particular relevance because the desired outcome is an observed change in symptoms, functioning and tolerability rather than a laboratory value alone. A concentration can be compatible with more than one clinical interpretation. It may reflect altered handling of the medicine, altered responsiveness at the site of action, an effect of illness, or a non-pharmacological explanation. The clinician's task is to preserve this differential rather than declare a concentration "effective" or "ineffective" in the abstract.

This distinction is also the reason a laboratory result cannot replace longitudinal observation. Pharmacokinetics helps explain exposure; pharmacodynamics helps explain the exposure-effect relation; clinical assessment establishes what is actually happening to the child. The three sources of information must be read together. This is a framework for thought, not a substitute for the broader monitoring and consent framework.

3.6 A disciplined approach to apparent variability

When response or tolerability appears out of proportion to the expected effect of a prescribed medicine, developmental pharmacology offers a structured sequence of questions. First, identify whether the concern is one of exposure, effect, or both. Second, consider whether developmental metabolism could alter bioavailability or elimination. Third, consider whether binding or intercurrent illness changes the interpretation of any measured concentration. Fourth, consider clearance, including renal processes when relevant. Finally, consider pharmacodynamic variation

and non-pharmacological explanations. This sequence prevents the common error of jumping from an unexpected outcome straight to an arbitrary dose change.

The sequence is deliberately explanatory rather than algorithmic. It does not tell the reader what dose to use, when to alter it, or what monitoring schedule to follow. Those decisions depend on the particular medicine, indication, evidence base, formulation, co-prescribed medicines, medical state and family context. General principles of child prescribing are addressed in the neighbouring prescribing fragment; off-label use and cautious titration are addressed in the fragment on off-label prescribing, dosing principles and start-low go-slow in children.

MNEMONIC

Entry, Binding, Clearance, Effect

Use this sequence to organise an unexpected response: ask what entered the circulation, what was bound, what was removed, and how the available exposure translated into the observed effect. It is a reasoning aid, not a dosing rule.

In child psychopharmacology, developmental physiology changes the path from prescribed amount to clinical effect, so dose, concentration and response must never be treated as interchangeable.

4 · Stimulants in children (recap, safety)

Why this matters clinically. A stimulant prescription is not made safe by a reassuring first review or by a neat entry on a prescription sheet. Safety lies in an organised follow-up relationship: the clinician remains alert to the child's changing body, daily functioning, family observations, and new clinical information. In a child, this matters especially because change can be gradual, expressed indirectly, or first noticed in a setting the prescriber does not see.

Stimulants are commonly discussed as if the important task were selecting a preparation and writing directions. That is not the focus here. The treatment decision and stimulant dosing in ADHD belong in *the ADHD and specific learning/communication disorders notes*. This section is a safety recap: it explains how to think during follow-up, what a useful record is trying to detect, and how to distinguish a measurement from a clinical conclusion.

4.1 Safety as a continuing clinical task

Therapeutic monitoring means using each contact to decide whether the current treatment plan still fits the child in front of the clinician. It is not an administrative ritual and it is not merely a search for adverse effects. The question is broader: what has changed since the last review, how reliable is the account of that change, and does the observed pattern call for attention, clarification, or a different plan?

This approach prevents contrasting errors. Therapeutic inertia occurs when a medicine continues simply because it was once started. Overreaction occurs when a difficult week is treated as proof that medication is responsible for every new problem. These errors arise when follow-up is

reduced to a simplified question about whether the medicine is "working." Children's lives do not present themselves in a simplified form. School demands, sleep, meals, family strain, developmental change, illness, and coexisting symptoms may all alter the picture without yielding a simple explanation.

RULE **At a stimulant review, measure change and interpret it in context before assigning a cause.** A safe review joins physical observations with the child's actual functioning and with a careful search for new medical or psychiatric concerns.

The established teaching account in a historical AACAP practice parameter is that follow-up should include review of behavioural and academic functioning, surveillance for emerging comorbidity or medical conditions, and **periodic assessment** of physical parameters. The wording is useful because it makes monitoring a clinical synthesis rather than a checklist detached from the child's life. It should be read as established teaching, not presented as a substitute for current local guidance or for individual clinical judgement.

A good review therefore begins with a narrative. Ask what the family, child, and relevant carers have actually observed, what has become easier or harder, and whether the report is consistent across settings. Then bring that narrative beside the recorded observations. The record is not there to overrule the family's account; it is there to make a trend visible and to reduce the chance that a meaningful change is missed because each visit is considered in isolation.

4.2 What should be kept in view at follow-up

The core physical safety recap is deliberately simple. At follow-up visits, **height**, weight, blood pressure, and pulse should be assessed periodically. The value of this set is not that any isolated entry automatically answers a clinical question. Its value is that it preserves a shared observational frame across visits. A record that is complete enough to compare is more useful than a collection of unconnected impressions.

Height	Weight	Blood pressure	Pulse
RECORDED OVER TIME	RECORDED OVER TIME	PHYSICAL REVIEW	PHYSICAL REVIEW

The clinical point is **trend recognition**. A value acquires meaning through method, context, and comparison with prior observations. Before deciding that a change is treatment-related, confirm that the measurement is credible and ask whether ordinary circumstances may explain it. Before deciding that a measurement is unimportant, ask whether it departs from the child's earlier pattern or occurs alongside a change in wellbeing or function. This disciplined middle position protects against both complacency and alarmism.

Physical review belongs beside functional review. The same historical AACAP account asks the clinician to review behavioural and academic functioning and to assess for emerging comorbid disorders and medical conditions. This is not an invitation to re-diagnose the child at every visit. It is a reminder that the presenting problem may evolve, that a coexisting difficulty may become more visible as one domain improves, and that treatment should not narrow the clinician's field of vision.

REVIEW DOMAIN	CLINICAL QUESTION	PURPOSE OF THE RECORD
Physical observations	Has there been a change that deserves verification or interpretation?	To make a pattern visible across contacts.
Behaviour and learning	What has changed in everyday participation and demands?	To connect treatment with the child's real-world function.
New symptoms or conditions	Is a fresh concern emerging that needs its own assessment?	To avoid attributing every development to medication.
Family and child account	Whose observations explain the change, and in which setting?	To test whether the clinical picture is coherent.

Growth surveillance is best understood as longitudinal observation, not as an isolated pass or fail event. A child may look well at an appointment while a gradual shift becomes apparent only when earlier records are available. Conversely, a concerning-looking entry may need repetition or contextual explanation before it is allowed to dominate a treatment decision. The same logic applies to **cardiovascular observation**: measure carefully, document clearly, and interpret a pattern rather than attempting to infer risk from an isolated decontextualised reading.

> **GOOD TO REMEMBER**
>
> Bring the physical record into the conversation. Showing a family the sequence of observations turns monitoring into shared clinical work and often clarifies whether the concern is a persistent pattern, an uncertain measurement, or a change in the child's wider circumstances.

4.3 Attribution: the central reasoning problem

The most important safety skill is **attribution**. An event that follows a prescription is not necessarily caused by it. Temporal proximity can be clinically important, but it is a starting signal for inquiry, not a conclusion. Children have intercurrent illnesses, altered routines, changing educational pressures, family events, developmental transitions, and untreated coexisting difficulties. A prescriber who ignores these alternatives may make an avoidable treatment change. A prescriber who uses them merely to dismiss a concern may miss a genuine problem.

Attribution is strengthened by detail. What exactly changed? When was it first noticed? Does it occur consistently or only in a particular setting? Has someone observed the same pattern independently? Was there a relevant change in routine, health, school, or family life? Have the basic observations been checked? These questions do not demand a formula. They create a defensible clinical account in which action follows evidence rather than anxiety.

It is useful to separate the tasks that are often muddled together:

- recognising that a new observation deserves attention;
- deciding what additional information is needed to understand it; and
- deciding whether the treatment plan should change.

Keeping these tasks separate improves both safety and communication. A parent can be taken seriously when a concern is recognised without the clinician prematurely promising a causal explanation or a medication change. It also leaves room for the child's own account. A child may describe an experience differently from a caregiver, and that discrepancy is information to explore rather than a nuisance to smooth away.

TRAP **Do not equate "reported after treatment" with "caused by treatment."** The equally unsafe opposite is to treat a report as irrelevant because the measurement is not yet conclusive. Record the concern, assess its context, and let the subsequent clinical picture guide the response.

Documentation serves the same reasoning purpose. It should state the concern in clinically neutral language, identify the informant and setting, record relevant observations, and make the plan intelligible to the next clinician. It should not turn a suspicion into an established adverse effect merely by the wording used. Precise notes protect the child from both fragmented care and retrospective certainty that was never actually earned.

4.4 Function is part of safety

Functional review is part of safety because a prescription that looks uncomplicated on a chart may still be poorly fitted to the child's life. The historical monitoring account specifically includes behavioural and academic functioning. The point is not to make academic performance the sole measure of treatment value, nor to reduce behaviour to a report from one adult. It is to ask whether the child's capacity to participate in ordinary expectations is changing and whether that change is experienced as helpful, burdensome, or ambiguous.

Function must be explored across the child's environments. A family may notice a different pattern from school, and neither account should be casually privileged. Apparent disagreement may reflect different demands, different observers, or a real context-dependent effect. The clinical task is to understand the discrepancy. In this respect, monitoring remains child psychiatry rather than a narrow drug review: the medicine is considered within development, relationships, education, and health.

When a child's functioning changes, resist the temptation to collapse the answer into "more" or "less" medication. First establish what is meant by change. Is the concern about attention, activity, distress, participation, conflict, tiredness, learning demands, or something else? What is the child's interpretation? Has the concern emerged alongside a medical or psychosocial change? This does not duplicate the treatment chapter; it explains why follow-up must preserve diagnostic curiosity even after a prescription has begun.

MNEMONIC

RAMP

Record the physical measurements, **A**sk about everyday function, **M**onitor new concerns and context, and **P**lan, summarised so the child and family can understand it. It is a recall scaffold for a review, not a dosing rule or a substitute for clinical judgement.

A clear summary at the end of the consultation is clinically useful. It states what has been heard, which observations were documented, what remains uncertain, and what change should prompt earlier contact. This protects against the family leaving with a vague sense that they have been reassured but no shared understanding of what is being watched. It also gives continuity when care is shared across clinicians or services.

4.5 Scope, currency, and the Indian examination answer

IN INDIA

For an Indian postgraduate answer, keep the stimulant safety paragraph distinct from the ADHD treatment paragraph. State that physical parameters and functional change are followed longitudinally, then direct the reader to *the ADHD and specific learning/communication disorders notes* for stimulant selection and dosing. This prevents an answer from importing a regimen into a question that is actually testing safe follow-up.

Safety advice often becomes unsafe when its scope is lost. A historical practice parameter can provide an enduring clinical principle while no longer functioning as a current, stand-alone protocol. The safe use of such teaching is transparent: identify the principle it contributes, preserve its limits, and check the current local policy or specialist advice when a contemporary operational decision is required. This is especially important when a trainee is tempted to convert a broad instruction to monitor into a rigid schedule, threshold, or universal response.

The practical distinction is between a **monitoring framework** and a management algorithm. A framework tells the clinician what domains deserve recurrent attention. An algorithm tells the clinician precisely what to do under defined circumstances. The supplied historical teaching supports the former. It does not license this section to invent the latter. Keeping that distinction explicit is both good scholarship and good clinical safety.

PITFALL

Do not present an older authoritative document as if it settles a current operational question. Its monitoring principle may remain useful, but current decisions require the applicable policy, the child's clinical context, and appropriate specialist judgement.

The same discipline applies to cross-references. The disorder formulation, diagnostic reconsideration, medication choice, and dosing details must not be smuggled into a safety recap merely because they are clinically adjacent. A focused answer is stronger: it says what the review must observe, why interpretation matters, and where the reader should go for treatment details.

4.6 A usable follow-up note

A concise follow-up note can carry considerable clinical intelligence when it links observation to interpretation. It should identify the child's and caregiver's account of change, note relevant behavioural and academic functioning, record whether fresh medical or psychiatric concerns have emerged, and preserve the physical observations required for longitudinal comparison. It

should then state the clinician's working interpretation and the agreed next step. This makes the reasoning visible rather than leaving a sequence of numbers with no clinical meaning.

The note should also preserve uncertainty honestly. "Concern reported, context under review" is often more accurate than a definitive label. It tells a future clinician that the issue was heard and that the current evidence did not yet justify a stronger conclusion. Honest uncertainty is not indecision. It is a deliberate safeguard against causal overstatement in a developing child whose circumstances may change quickly.

Stimulant safety follow-up is longitudinal: **periodically** record physical parameters, review real-world function, and investigate new concerns before deciding what they mean.

5 · Antipsychotics in children (indications, metabolic monitoring)

Why it matters clinically. An antipsychotic prescription in a child is never simply a choice of molecule. It is a decision to target a clearly described symptom pattern, within a developmental formulation, while accepting the obligation to look actively for physical harm that the child may neither recognise nor report. The useful examination answer is therefore not a list of drugs. It is a disciplined account of indication, scope, baseline metabolic monitoring, review of benefit, and a route back to the wider treatment plan.

In child psychiatry, these medicines are often discussed around highly visible behaviours, but visible behaviour is not itself an indication. The clinician must specify what is being targeted, how it is impairing the child or others, what non-pharmacological work is proceeding, and what observable change would justify continuing treatment. Antipsychotics can have an important place in carefully selected situations; they should not become a substitute for developmental assessment, family work, environmental modification, or treatment of the disorder that gives the symptom its meaning.

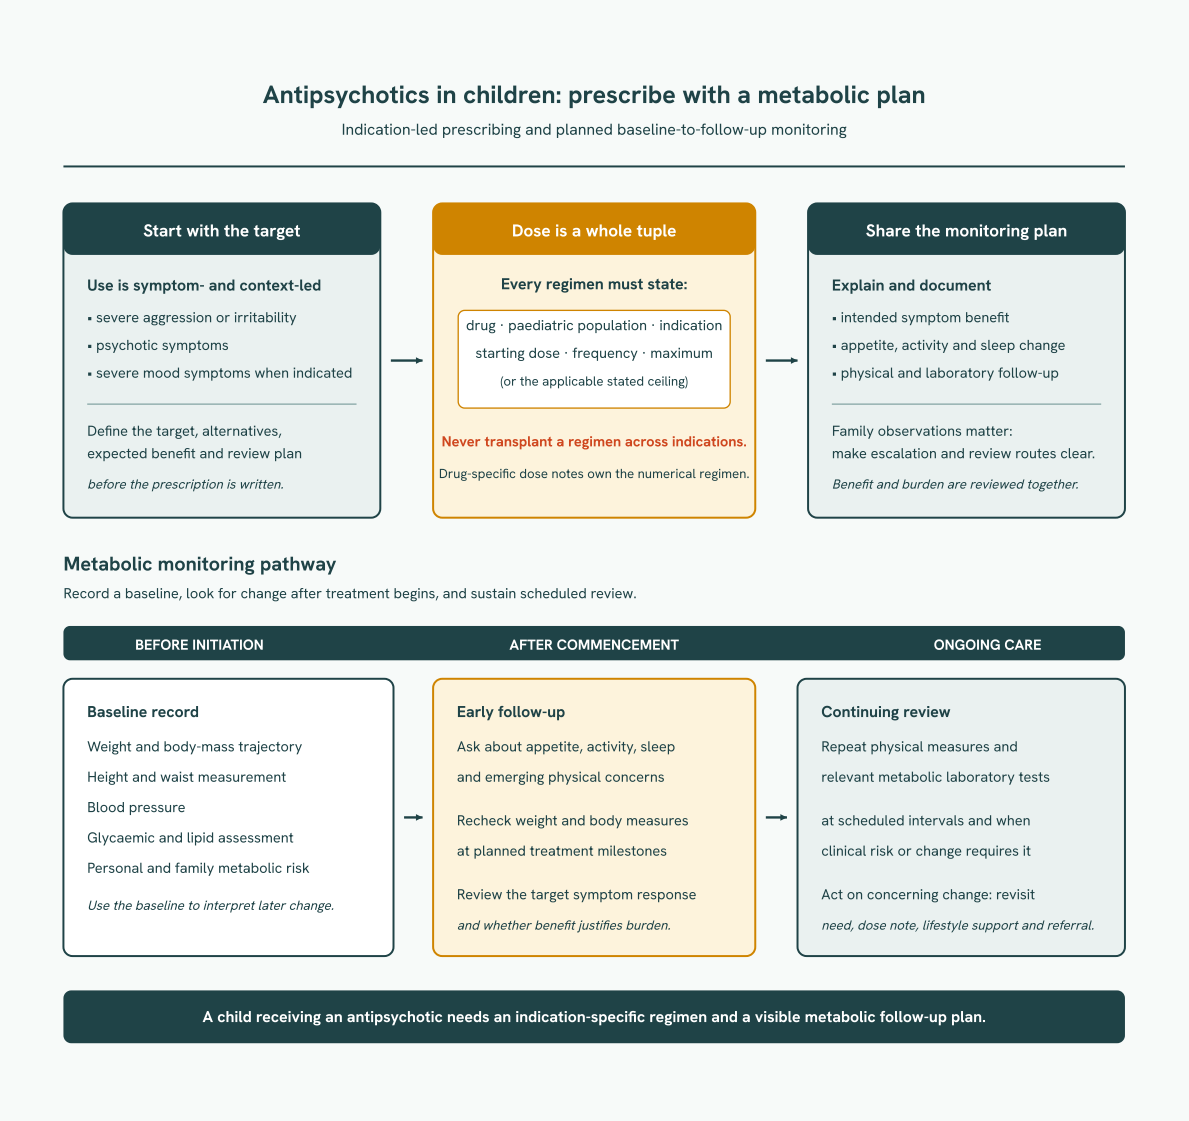

Fig 24.4. Antipsychotic prescribing in children is indication-led: a complete dose tuple belongs to the drug-specific prescribing note, while metabolic monitoring begins before initiation and continues through treatment.

5.1 The indication is a clinical question, not a behavioural label

A **target symptom** is the concrete phenomenon that the prescription is intended to change. It should be described in language that permits subsequent review: its form, setting, precipitants, consequences, and effect on functioning. This prevents the common slide from "difficult behaviour" to medication without a defensible therapeutic question. A severe behavioural presentation may arise from distress, communication difficulty, fear, pain, sleep disruption, conflict, a neurodevelopmental need, an emerging mood or psychotic state, or a safeguarding problem. Medication may be relevant to some formulations, but it cannot settle which formulation is correct.

The prescriber should translate the referral complaint into a working hierarchy. Immediate risk and intolerable suffering take priority, but urgency does not abolish assessment. The practical question is whether an antipsychotic is being considered to relieve a symptom pattern for which it is reasonable, or merely to make a setting easier to manage. The latter may occur when a family,

school, ward, or residential placement is overwhelmed. Their burden deserves attention, yet social strain alone is not an adequate endpoint for a child's long-term medication exposure.

RULE **Prescribe against a stated target and a stated review question.** The target tells the team what benefit to seek; the review question tells the team what would count as insufficient benefit, unacceptable harm, or a reason to change course.

A **functional formulation** protects against treating a symptom in isolation. It links the behaviour or experience to antecedents, developmental abilities, relationships, reinforcement, medical contributors, and the child's environment. The formulation also clarifies what medication cannot accomplish. A medicine may reduce a particular symptom, but it does not teach communication, repair attachment strain, alter a coercive interaction cycle, or create an appropriate educational placement. Those tasks remain active parts of care.

5.2 Scope discipline: named examples are not portable regimens

Regimens in child psychiatry are inseparable from the indication and population for which they were established. A drug name written beside a diagnosis can falsely imply that the same approach applies to every child with that diagnosis, every behavioural difficulty, or every service setting. That inference is especially unsafe with antipsychotics, where the balance between expected benefit and physical burden varies with the clinical problem and the individual child.

For a child with tics, **aripiprazole** may be named as a cross-referenced example; its tic regimen is taught in *the Child behavioural, emotional and other disorders notes*. Likewise, **risperidone** may be named in relation to conduct-disorder aggression, but that regimen belongs to *the Child behavioural, emotional and other disorders notes*. The relevant population and indication must accompany any reading of current labelling. These references are deliberately narrow. They neither authorise a regimen for another presentation nor provide a dose that can be lifted into another clinical context.

Risperidone may also be named as a cross-referenced example for autism-related irritability; its regimen is taught in *the Intellectual disability and autism spectrum disorder notes*. This distinction is more than editorial tidiness. When a child's presentation is linked to autism, the diagnostic formulation, communication profile, sensory context, family goals, and behavioural supports shape the treatment decision. A medication name alone cannot carry that work.

PITFALL

Do not convert a cross-referenced example into a general-purpose prescription. The same antipsychotic may appear in more than one part of child psychiatry, but each use has its own clinical question. A dose or titration recalled from one indication is not evidence for another.

PRESCRIBING QUESTION	WHAT THE RECORD SHOULD MAKE CLEAR	WHY IT MATTERS
What is being treated?	The target symptom and its functional impact.	It prevents medication from becoming a response to an unspecific label.
Why medication now?	The clinical rationale, urgency, and the work already underway around the child.	It keeps pharmacotherapy within a multimodal plan.
What benefit is expected?	A change that the child, carers, and team can recognise.	It makes continuation a clinical decision rather than an automatic renewal.
What harm is being watched for?	Physical measures and the plan for responding to change.	It gives metabolic monitoring the same status as symptom review.
Who will review the plan?	Named clinical responsibility and communication with carers.	It reduces fragmented prescribing across services.

5.3 Metabolic monitoring is part of the prescription

Metabolic monitoring is not an administrative appendix added after the therapeutic decision. It is the means by which the clinician makes the physical cost of treatment visible. Children may have limited language for bodily change, may depend on adults to arrange investigations, and may experience the effects of appetite change, weight change, tiredness, or altered self-image within family and school systems. Monitoring therefore belongs in the initial conversation and documentation, not only in a later laboratory request.

The metabolic monitoring schedule begins before treatment. Before starting an antipsychotic, record **weight or BMI**, **pulse**, **blood pressure**, and a **fasting blood glucose or HbA1c** together with a **blood lipid profile**. These baseline measures create a comparison point. Without them, later change is difficult to interpret and an emerging physical problem can be wrongly attributed to lifestyle, family care, or the child's condition.

Before treatment	Target	Physical change	Family
BASELINE RECORD	CLINICAL BENEFIT	ACTIVE REVIEW	SHARED OBSERVATION

The phrase "metabolic" should not narrow the clinician's attention to a test result. It is a clinical frame for considering bodily change over time and its implications for adherence, confidence, participation, and future health. A child who is gaining weight, distressed about appearance, avoiding activity, or receiving stigmatising comments from peers may not volunteer the connection to treatment. A respectful review asks directly, avoids blame, and includes the carers who organise meals, appointments, and daily routines. It also leaves room for the child's own account of whether the medicine's benefit is worth its burden.

Baseline measurement is not a hurdle designed to delay necessary treatment. Its purpose is to make later judgement more honest. Where clinical circumstances require prompt action, the

prescriber should still document what is known, arrange the outstanding physical work, and make clear who is responsible for seeing the information. The error is not acknowledging uncertainty; the error is allowing an urgent start to become a reason that safety information is never assembled. In the same way, a normal baseline does not predict that the child will remain unaffected. It simply gives the clinician and family a reliable starting point for noticing change.

TRAP **Do not treat baseline tests as permission to stop thinking about physical health.** Baseline information is useful only when it is compared with the child's subsequent clinical course and when concerning change leads to a renewed benefit-harm decision.

5.4 Turning measurement into clinical review

A **benefit-harm review** joins symptom observation to physical monitoring. If the target has not materially changed, the prescriber should not let elapsed time turn an unsuccessful trial into indefinite exposure. If there is benefit but emerging burden, the task is to reconsider the entire plan: the clarity of the target, whether the formulation has changed, the role of psychosocial interventions, the acceptability of the treatment to the child and carers, and whether continued medication remains proportionate.

Review is strongest when it uses information from more than one setting. Carers may observe sleep, appetite, activity, irritability, and family functioning. The child may describe internal experience, embarrassment, sedation, or a change that adults have missed. School observations can help distinguish a home-specific improvement from a more general functional change, while also revealing environmental demands that medication cannot solve. Disagreement between informants is data, not inconvenience. It may show that the target was too broad, that the context differs, or that a desired benefit is being purchased at a cost visible only in one setting.

- Return to the original target symptom rather than asking only whether the child is "better".
- Ask the child about bodily and social effects in language they can use.
- Review the carers' observations without allowing convenience to become the sole outcome.
- Connect physical findings to a documented decision about the treatment plan.

General monitoring and consent issues in child psychopharmacology require their own framework. In particular, the clinician should not mistake parental agreement for a complete account of the child's participation in care, nor allow the technical work of prescribing to crowd out collaborative explanation. The antipsychotic-specific contribution here is that physical monitoring should be explained as a shared safety task from the outset.

5.5 The child, family, and service context

Shared observation is clinically valuable because antipsychotic effects unfold in ordinary life rather than only in the consulting room. Carers need a plain explanation of the symptom being targeted, the changes that should be reported, and the purpose of metabolic monitoring. The child should receive an explanation suited to their developmental and communication level. This is not merely good manners. A child who understands that appointments include attention to

how their body feels is more likely to disclose a problem than one who experiences investigations as unexplained adult activity.

Service design affects safety. The record should make it possible for a clinician meeting the child later to see why the medicine was begun, what has changed, what baseline measures were obtained, and which team member will act on new information. A prescription without that trail can persist through handovers because no individual feels able to revisit the original decision. Conversely, clear documentation supports a proportionate review even when services are busy or the child is seen across settings.

Physical monitoring can also strengthen, rather than weaken, the therapeutic alliance. When its rationale is discussed openly, the child is less likely to experience weighing, blood-pressure measurement, or blood tests as punishment for behaviour. Families can then bring concerns early instead of assuming that appetite, appearance, tiredness, or reluctance to attend school are unrelated problems. The clinician's task is to hold both truths at once: distressing symptoms may need active treatment, and the treatment itself deserves the same careful attention as the symptoms it aims to relieve.

IN INDIA

Children may move between private consultation, hospital care, school-linked support, and family-led follow-up. The prescriber should make the indication and metabolic monitoring plan legible across those settings. A terse drug list is particularly unsafe when the next clinician cannot tell what symptom is being treated or whether physical baseline information exists.

GOOD TO REMEMBER

When a carer reports that a medicine has "settled" a child, ask what has actually changed: distress, aggression, sleep, participation, communication, or simply manageability. The answer determines whether the benefit is meaningful and whether the rest of the formulation still needs attention.

5.6 A disciplined answer in practice and in examinations

A concise but safe answer to an antipsychotic question starts with indication-specific reasoning, not a medication list. It then states that the child's broader formulation and psychological, family, educational, and environmental interventions continue alongside any prescription. Next, it names baseline metabolic monitoring and explains that the measures must inform ongoing review. Finally, it distinguishes a cross-reference from a regimen: named examples point the reader to the chapter that owns the particular condition and dose.

This structure is also useful at the bedside. It makes the clinical team declare what they are trying to change, invites the child and family into observation, and keeps physical health within the same decision loop as behavioural or emotional improvement. It is possible for an antipsychotic to be appropriate and still require active reconsideration. That is not indecision. It is the expected discipline of prescribing a powerful medicine to a developing person.

An antipsychotic prescription for a child is complete only when its target symptom, indication-specific scope, and metabolic monitoring plan can all be read from the clinical record.

6 · Antidepressants in children (SSRIs, black-box warning)

Why this matters clinically. Antidepressant prescribing in a young person is not a miniature version of adult prescribing. The clinical encounter contains a diagnostic formulation, a developmental formulation, the child's and family's account of what treatment is meant to change, and a decision about whether a medicine has a place at all. This section narrows deliberately to the safe reading of one paediatric depression regimen. That narrowness is useful: a dose can look deceptively portable when copied into a note, an examination answer, or a handover, yet it only has meaning when its indication and population travel with it.

Thus, **fluoxetine** is placed first here as the antidepressant whose current paediatric depression label supplies a usable regimen. The chapter does not turn that label into a general account of childhood depressive disorders, an argument for a particular treatment sequence, or a template for every SSRI. Those matters require the disorder formulation and the evidence base that belongs with it. A prescriber's task is to keep the medicine, the clinical problem, the developmental context, and the source of the dose in one sentence rather than allowing any one of them to substitute for the others.

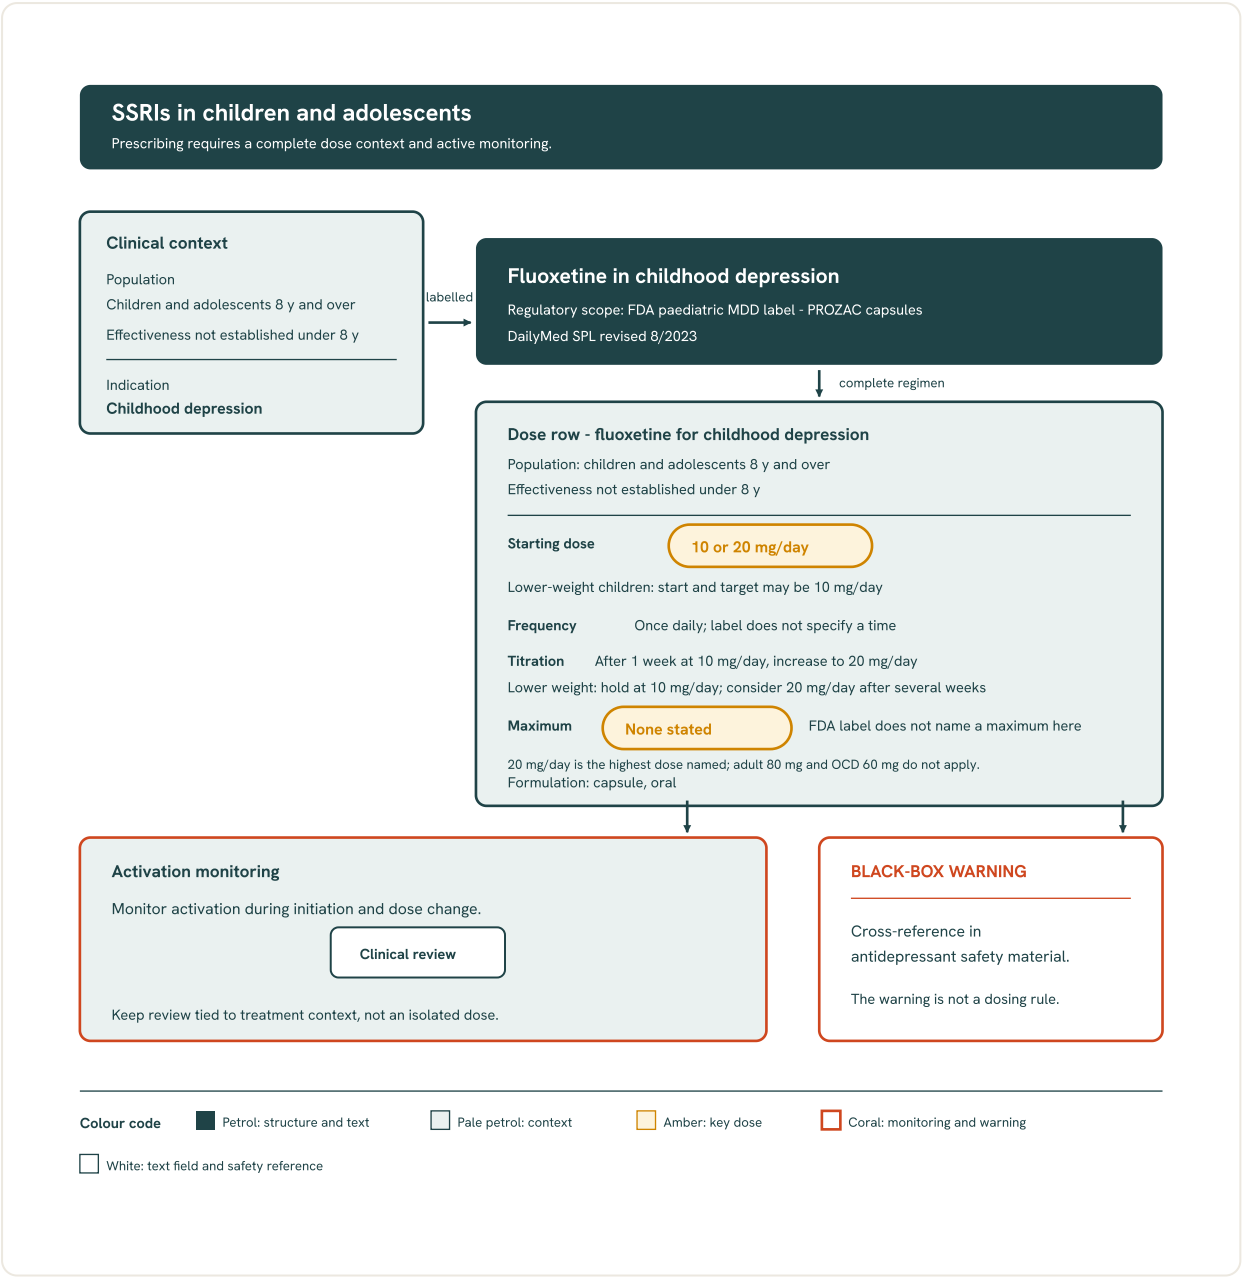

Fig 24.5. Fluoxetine is presented with the complete labelled regimen for childhood depression in the stated paediatric population. Monitor activation at initiation and dose change; handle the black-box warning through the linked safety reference.

6.1 What this section does and does not establish

The term **paediatric indication** is the essential boundary. A regulatory regimen answers a constrained question: for whom, for which named clinical use, and on what schedule has this product information been written? It does not decide that the young person in front of the clinician has that condition, that medication is sufficient treatment, or that the same wording can be exported to another indication. The dose is therefore read at its origin, not treated as a detached property of the molecule.

This distinction matters in both ward and outpatient work. Clinical teams often inherit a medication list without the reasoning that led to it. A copied drug name may survive while the original target symptoms, developmental context, and intended endpoint disappear. Restoring the missing sentence is a safety task. The clinician should be able to say what problem is being

treated, why this medicine is being considered for that problem, and which source governs the proposed regimen. If that cannot be said clearly, a dose entry should not masquerade as a complete treatment decision.

RULE **A paediatric antidepressant dose is a clinical tuple, not a standalone number.** Keep the drug, the indication, the population, the frequency, the route of change, and the ceiling statement together whenever a regimen is written or communicated.

The assessment and diagnostic work that decides whether childhood depression is the relevant formulation belongs with the childhood disorders and their assessment, rather than with a dosing paragraph. Likewise, a discussion of psychotherapy, family intervention, school support, or service referral cannot be replaced by a prescription. Naming these limits is not evasive. It prevents the dose from being used as a shortcut around the clinical work that makes prescribing intelligible.

6.2 The labelled fluoxetine regimen for childhood depression

For children and adolescents **8 years and over** with **childhood depression**, the current FDA product label describes oral fluoxetine at a starting dose of **10 mg/day** or **20 mg/day**, given once daily. The paediatric paragraph states no time of day; the once-daily-in-the-morning instruction appears in the adult depression section of the label and is not carried into the paediatric text. When the lower amount is used, it is increased after **1 week** to a target of **20 mg/day** for childhood depression. In lower-weight children, the label states that the starting and target dose may be the lower amount, and that an increase to the higher target may be considered after several weeks if clinical improvement is insufficient. The maximum statement must be retained separately: in childhood depression the target is **20 mg/day**, and the label does not name a maximum of any kind for this paediatric indication. The ceilings it prints elsewhere belong to adult depression and to paediatric obsessive-compulsive disorder, and neither may be carried across to childhood depression.

The wording above is intentionally complete. A range alone is not a regimen, because it does not tell the reader whether the range describes initiation, a target, or a limit. Nor does a target substitute for a maximum statement. Here, the paediatric paragraph simply does not state a separate weight-based ceiling, and that silence must be reported as silence. It should not be rewritten as an invented weight-based rule, and it should not be silently converted into permission to extrapolate beyond the labelled target.

Scope	Schedule	Change	Ceiling
DRUG + POPULATION + INDICATION	ONCE DAILY, NO STATED TIME	LABELLED STEP TO TARGET	STATE IT EXPLICITLY

PRESCRIBING ELEMENT	WHAT MUST REMAIN ATTACHED TO THE DOSE	WHY IT MATTERS
Drug	The exact medicine named in the label	Prevents a class label from replacing a medicine-specific regimen.
Population	The age and developmental scope stated by the source	Prevents use of a paediatric statement outside the population it addresses.
Indication	Childhood depression, not an implied alternative use	Prevents a regimen from migrating across diagnoses.
Starting plan	Initial amount, timing, and route of increase	Makes the first prescription reproducible and reviewable.
Target and ceiling	A target statement plus the label's ceiling language	Stops a range from being mistaken for either of these distinct ideas.

Write the whole regimen sentence: medicine, child population, indication, start, schedule, titration, target, and ceiling statement.

6.3 Why the lower-weight pathway is clinically meaningful

The phrase **lower-weight children** is not decorative label language. It signals that a young person's developmental and bodily context can alter the labelled starting and target plan even when the diagnostic indication is unchanged. The prescriber should therefore resist a crude age-only reading of a paediatric regimen. The relevant question is not whether the child resembles an adult closely enough to receive an adult-looking dose. It is whether the particular labelled pathway describes this child's population and clinical situation.

That is a reasoning discipline rather than a numerical trick. Weight, maturity, medical comorbidity, concurrent treatments, formulation practicalities, and the family's ability to observe change all shape how a prescription is implemented. The general developmental pharmacology of childhood, the broader principles of cautious titration, and the operational framework for monitoring are discussed elsewhere in this chapter. They should inform the encounter, but they must not be reverse-engineered into an unsourced alternative regimen.

- Identify the clinical indication before opening a dosing source.
- Check that the child fits the population described by that source.
- Preserve the lower-weight branch when it is the relevant labelled pathway.

GOOD TO REMEMBER

A prescription is easier to review when the rationale is written next to it. Record the treatment target in ordinary clinical language and retain the label-based regimen sentence in the medication plan. This allows the next clinician to distinguish a considered paediatric plan from a number that has simply been carried forward.

6.4 Titration is a decision point, not automatic escalation

The instruction to move from the lower start to the higher target is often read as a mechanical sequence. It is better understood as a planned review point. The label supplies the timing and target for its defined population; clinical work supplies the observation and interpretation that surround that plan. A clinician must still know what change is being sought, what the family has observed, whether the medicine is being taken as intended, and whether the formulation remains coherent. These are not reasons to improvise a new dose. They are reasons to decide whether the labelled pathway remains the relevant one.

There is a useful separation of roles. The label governs the regimen stated here. The therapeutic relationship makes observations usable: a young person and caregiver need language for describing benefit, distress, activation, withdrawal from usual activity, and changes that matter to them. The formal framework for monitoring, consent, assent, shared decision-making, and review cadence is owned by the child psychopharmacology section on monitoring and consent. This section names that framework but does not duplicate it.

TRAP **Do not write a target dose as though it were a command to escalate regardless of the child's course.** The target belongs to a defined regimen; the decision to continue along that pathway remains clinical and must be documented in the wider monitoring framework.

Equally, avoiding automatic escalation does not mean replacing the label with unstructured hesitation. Ambiguity can be just as unsafe as overconfidence when it produces unclear instructions for caregivers or a fragmented handover. The safe middle position is explicit: the intended plan is recorded, the source is identifiable, and any departure from the plan has a stated clinical reason rather than an accidental drift.

6.5 The source of a paediatric dose is part of the prescription

The regimen in this section is scoped to the **FDA paediatric MDD label**. This is a source statement, not a claim that regulatory status, product availability, or local practice is identical in every jurisdiction. Current labelling deserves priority over remembered textbook tables because a dose is especially vulnerable to becoming stale when it is detached from its source. A well-written clinical note therefore makes the source visible enough for another clinician to verify it rather than presenting the dose as timeless common knowledge.

Source discipline also improves examination answers. A candidate who writes only a drug and an amount has shown recall but not safe prescribing reasoning. A stronger answer identifies the population and indication, gives the starting plan and once-daily schedule, explains the move toward the target, and records the ceiling statement. It then separates this factual regimen from the broader question of whether the child needs medication, psychological treatment, family work, school intervention, or a different level of care.

PITFALL

Do not infer an Indian paediatric depression approval merely because a United States product label carries a paediatric regimen. The regimen printed here is explicitly sourced to that label. Local regulatory status and available formulations must be checked at the point of prescribing.

6.6 Boundaries with the SSRI suicidality warning

The paediatric SSRI black-box suicidality warning itself is not taught here. It belongs to *the Child behavioural, emotional and other disorders notes*, where it should be read in its disorder-level context. This cross-reference matters because a warning is neither a reason to minimise distress nor a substitute for a full risk formulation. Conversely, a brief mention of a warning must not be allowed to become a generic warning paragraph that is repeated wherever an antidepressant is named.

For the prescribing encounter, the practical implication is architectural. The medicine-specific regimen is documented here; the warning and its clinical interpretation are sought in the named cross-reference; and the general monitoring-and-consent framework is sought in its owning section. Keeping these layers separate prevents a false choice between pharmacological precision and safety. Both are required, but they are not the same construct and should not be taught as though a dose table alone can carry either one.

- Use the disorder chapter for the paediatric SSRI black-box suicidality warning.
- Use the child psychopharmacology monitoring-and-consent section for its general framework.
- Use the current product label for the regimen attached to its indicated population.

6.7 An Indian prescribing stance

IN INDIA

Use the regimen here as a clearly labelled regulatory reference, not as a shortcut to local authorisation. In Indian practice, verify the currently available formulation, the applicable local regulatory information, and the service pathway for the child and family. Documentation should make clear whether the prescribing decision rests on a locally applicable indication or on a separately justified clinical decision.

This stance avoids two opposite errors. One is therapeutic nihilism, in which the clinician treats uncertainty about a label as a reason not to formulate or treat. The other is regulatory overreach, in which an overseas label is cited as if it settles every local clinical and legal question. Neither helps the child. The disciplined approach is to identify the clinical need, use the correct source for the exact regimen being considered, and state openly what that source does and does not establish.

The larger child psychiatry system remains visible in the background. Family engagement, psychological treatment, school coordination, and safeguarding may all determine whether a medication plan can be used safely and meaningfully. They are not adjuncts to be remembered after a dose is chosen. They are parallel components of care, each requiring its own assessment,

intervention, and documentation. This section contributes one precise element: how to read and communicate the fluoxetine label without letting that precision spill into claims the source does not support.

7 · Mood stabilizers in children and adolescents

Why it matters clinically. A mood-stabiliser prescription in a young person is not a class-level decision. It is a tightly bounded clinical instruction: the drug, the indication, the child for whom the regimen was read, the way it is introduced, the safety work that makes continuation defensible, and the point at which the prescriber must reconsider. This matters especially when a familiar adult regimen is being discussed in a family meeting. Familiarity can make a dose look portable when its evidence and label scope are not.

This section is deliberately about the prescription and its safety architecture, not about diagnosing bipolar disorder or choosing a syndrome-level treatment pathway. Those clinical formulations belong with the childhood disorders in *the Child behavioural, emotional and other disorders notes*. General mood-stabiliser pharmacology is considered elsewhere. Here, the candidate should be able to read a regimen as a complete sentence and explain what must accompany it in real practice.

7.1 Reading a paediatric regimen as a whole

The useful unit of learning is the **regimen**, not the isolated milligram figure. A dose becomes clinically meaningful only when attached to a named indication and an explicitly described population. It must also state how the dose changes and where the upper boundary lies. If a label names no milligram ceiling, that silence must be reported as silence rather than as a statement that no ceiling exists; it tells the reader that a serum-guided endpoint, rather than a memorised tablet count, is doing the limiting work. The doses below are read at their regulatory-label origin; the table preserves source-specific scope instead of exporting it across settings.

That distinction protects against opposite errors. Under-reading copies the starting dose without the titration or monitoring plan. Over-reading treats an adult regimen or a foreign label as though it establishes local paediatric approval. Neither error is repaired by adding a vague warning such as “monitor closely.” The prescriber must state what is being monitored, why it is being monitored, and how the result changes the next decision.

RULE **Never quote a paediatric mood-stabiliser dose without its indication, population, titration and ceiling statement.** The dose is only an element of the instruction. Separating it from the rest creates a prescription that sounds precise but is clinically incomplete.

MNEMONIC

SCOPE

Specific indication, **C**hild population, **O**rigin of the regimen, **P**lan for titration and monitoring, and **E**ndpoint or ceiling. Use it before writing the order and again before explaining it to a family.

SCOPE	LITHIUM	VALPROATE	LEVELS
READ THE WHOLE ORDER	LABEL-SCOPED REGIMEN	OFF-LABEL CAVEAT	SAFETY DECISION POINTS

MEDICINE	INDICATION AND POPULATION	STARTING PATH AND CEILING	SAFETY READING
Lithium carbonate	Paediatric bipolar mania in **patients aged 7 years and older who weigh over 30 kg**	**Start at 300 mg three times daily in divided doses, increase by 300 mg every 3 days, and obtain serum lithium at 3 days, drawn 12 hours after the last dose, to guide titration. Maximum: the label names no milligram ceiling for this population; it gives usual dose ranges of 600 mg two to three times daily acutely and 300 to 600 mg two to three times daily for maintenance, and the limiting endpoint is the serum level, with an acute target of 0.8 to 1.2 mEq/L.** Source: US FDA lithium carbonate label, revised October 2022.	Use the baseline and continuing lithium monitoring plan (NICE CG185).
Lithium carbonate	Paediatric bipolar mania in **patients aged 7 years and older who weigh 20 to 30 kg**	**Start at 300 mg twice daily in divided doses and increase by 300 mg weekly, not every 3 days. Maximum: the label does not state a milligram maximum for this weight band. It gives dose ranges, not ceilings: an acute range of 600 to 1500 mg daily in divided doses and a maintenance range of 600 to 1200 mg daily in divided doses. The serum targets are the same as the heavier band, 0.8 to 1.2 mEq/L acute and 0.8 to 1.0 mEq/L maintenance.** Source: US FDA lithium carbonate label, revised October 2022.	Use the baseline and continuing lithium monitoring plan (NICE CG185).

MEDICINE	INDICATION AND POPULATION	STARTING PATH AND CEILING	SAFETY READING
Divalproex sodium	Bipolar mania: use in children is **off-label**.	The label establishes **no paediatric population** for this indication, so it carries no paediatric regimen. The adult mania regimen is deliberately not reproduced here: it is not transferable to a child, and printing it invites exactly that transplant. Dose only against a current label or a specialist protocol written for the child in front of you.	Make teratogenicity and the indication-specific evidence limitation explicit.

At every medication review, the order should make the following questions answerable:

- What exact indication is this medicine treating?
- Which child population does the regimen describe?
- What dose has actually been taken since the last review?
- What monitoring result is needed before the next decision?
- What is the action if benefit, safety, or feasibility changes?

7.2 Lithium carbonate: a scoped paediatric regimen

Lithium carbonate is the regimen in this section with a paediatric label scope for bipolar mania. The population boundary in the table belongs in the verbal handover, in the prescription record, and in the clinician's own reasoning. It prevents a dose learned for one child from becoming an unexamined default for another. The label sets out two paediatric weight bands, and they differ in starting frequency and in titration interval, so the band must be read before the number is used: the lighter band starts twice daily and is increased weekly, not three times daily and **every 3 days**.

The dose path is deliberately written as a sequence rather than a target tablet total. The maximum statement is as important as the start: a serum-guided endpoint is not permission to keep escalating by habit. A candidate should not substitute a remembered serum target from another setting for this label-scoped instruction.

Serum guidance does not make the clinical task mechanical. A concentration can be technically obtained yet be unhelpful if the timing, recent dose changes, adherence, fluid intake, intercurrent illness, or interacting treatment have not been reviewed. The result must be interpreted alongside the child's current clinical state and adverse-effect enquiry. This is why the medication review needs to preserve a clear sequence: what was prescribed, what was actually taken, what was measured, and what action follows. The level is a safety and dosing tool, not a substitute for reviewing the child.

GOOD TO REMEMBER

When handing over lithium care, write the indication and population beside the current dose. A future clinician can then see whether the regimen has remained within the scope in which it was originally selected, rather than mistaking a continuation dose for a universal rule.

7.3 Valproate: make the off-label boundary visible

Divalproex sodium, a valproate preparation, requires a different reading discipline in bipolar mania. No paediatric regimen is supplied here, and that absence is itself the teaching point: paediatric bipolar efficacy is not established, the label carries no paediatric population for this indication, and use in children is therefore off-label. The adult regimen is deliberately not reproduced, because a number printed in a paediatric chapter is a number that gets transplanted. Off-label is not a euphemism for routine. It means the prescriber should be able to articulate why this medicine is being considered for this child, what evidence limitation is being accepted, and what alternative plan exists if benefit does not emerge.

Where a specialist protocol does supply a regimen for a particular child, the same discipline applies to it: increase only to the lowest therapeutic dose, use the trough concentration to guide that judgement, and state the maximum as a distinct safety statement rather than letting it disappear into a dose range or be inferred from the starting instruction.

In an adolescent girl, **teratogenicity** is a hard caveat, not a footnote. The clinical conversation must make reproductive risk visible before treatment is normalised by routine follow-up. The record should show that the risk was discussed in developmentally appropriate language, that family involvement was handled within the applicable consent process, and that a plan exists for any change in pregnancy possibility or treatment circumstances. This is not a reason to withhold thought; it is a reason to make the thought auditable.

TRAP **Reciting a valproate mania dose as though it were "a paediatric bipolar dose".** No paediatric regimen is supplied here, because the label establishes no paediatric population for this indication; any figure recalled from elsewhere is an adult mania number, and the child and adolescent bipolar indication remains off-label. State both facts together, or the answer becomes unsafe.

IN INDIA

Do not infer an Indian paediatric bipolar approval from a regimen read in another regulatory setting. The supplied lithium dose is label-scoped, and no paediatric valproate regimen is supplied here at all, because that use in children is off-label. Check the locally available product information and document the indication-specific rationale rather than allowing a foreign label to stand in for local regulatory status.

7.4 Lithium before treatment: establish a safety baseline

Before lithium is started, **baseline monitoring** should include weight or BMI, urea and electrolytes including calcium, estimated glomerular filtration rate, thyroid function, and a full blood count. An ECG is arranged when cardiovascular disease or its risk factors make that

relevant. The point is not to accumulate investigations. Each element creates an interpretable reference point for later treatment decisions and exposes a reason to pause, clarify, or coordinate care before the medicine is introduced.

Baseline work is also an opportunity to prevent false reassurance. A result should be linked to a plan, not simply marked “normal” in a checklist. If a child already has a medical issue that could complicate interpretation, the prescriber needs a shared plan with the relevant clinician and a clear account of which service will act on an abnormal result. That is especially important during transfer between inpatient, outpatient, and emergency care, where an old result may be mistaken for a current baseline.

The family needs a practical explanation of why blood tests are part of treatment rather than evidence that something has gone wrong. A calm explanation improves the chance that sampling, review, and dose decisions happen in the intended sequence. It also makes room for the child’s experience of procedures and for barriers such as travel, school timing, or fear of venepuncture. Those are not peripheral details. If they are ignored, a theoretically sound monitoring plan may never become a usable treatment plan.

PITFALL

Do not treat a recent laboratory sheet from another encounter as automatically adequate lithium baseline work. Its clinical meaning depends on timing, completeness, and whether it answers the pre-treatment question now being asked.

7.5 Lithium concentrations and maintenance surveillance

Two authorities meet in this section, and it is worth naming them. The dose pathway in the table is read at the US FDA lithium carbonate label (revised October 2022); the monitoring cadence below is taken from NICE Clinical Guideline CG185. The label instruction, a **serum lithium at 3 days drawn 12 hours after the last dose**, is the label instruction for the days immediately after a dose is set. The guideline cadence, measured **1 week after starting and 1 week after every dose change**, expressly covers the same titration period, so the two sources genuinely differ on when the post-change sample is taken. This is a real divergence and not a division of labour: name the source you are following, follow it consistently, and do not blend the two into a single invented schedule. Once titration is settled, early lithium monitoring has a defined rhythm. **Measure plasma lithium 1 week after starting and 1 week after every dose change, then weekly until stable; during the first year, measure it every 3 months.** This is best understood as a series of clinical decision points. After initiation and each adjustment, the team is checking whether exposure has become stable enough to move from active titration into maintenance. The later interval guards against the quiet drift that can occur after a seemingly settled prescription.

Maintenance monitoring is broader than the plasma concentration. **Maintenance monitoring** includes weight or BMI, urea and electrolytes including calcium, estimated glomerular filtration rate, and thyroid function **every 6 months**. Monitoring should be more frequent when there is evidence of impaired renal or thyroid function, raised calcium levels, or an increase in mood

symptoms that might be related to impaired thyroid function. That last trigger is the one a psychiatrist is most likely to meet first, because the presenting change is psychiatric rather than biochemical. The distinction between the level schedule and the organ-function schedule is worth preserving in notes and handovers: they answer different questions and neither replaces the other.

A useful review asks whether the agreed monitoring has actually occurred, whether the sample and the dose history can be interpreted together, and whether the child or family has noticed a change that should alter the plan. This is careful longitudinal prescribing, not a ritual laboratory task. If monitoring cannot be completed reliably, the clinician must address that limitation directly rather than letting refills conceal an unfulfilled safety plan.

> For paediatric mood stabilisers, the safe answer is the whole regimen: indication, population, dose pathway, ceiling, and monitoring - never the milligram figure alone.

8 · Monitoring and consent issues in child psychopharmacology

Why it matters clinically. A prescription for a child is not complete when the medicine is written. It becomes clinically defensible only when the prescriber has made a plan to observe benefit, detect burden, hear the child's experience, and revise the plan with the family. Monitoring is therefore not clerical follow-up. It is the method by which an initial prescribing hypothesis is tested in ordinary life: at home, in school, and in the child's own account of how treatment feels.

Consent is inseparable from that process. A parent or legally appropriate decision-maker may provide permission, but treatment is more likely to be understood and sustained when the child is included in a developmentally meaningful conversation. The psychiatrist must distinguish explanation, agreement, assent, consent, and legal authority without turning the consultation into either a signature exercise or a negotiation in which safety is abandoned. This section addresses the monitoring-and-consent framework around child psychopharmacology. Drug-specific adverse-effect schedules and dosing belong with the relevant medicine classes.

Review	Monitor	Discuss	Record
EFFECT	BURDEN	CHOICE	DECISION

8.1 Monitoring is a clinical loop, not a checklist

The purpose of a **monitoring plan** is to make the next clinical decision easier and safer. Before treatment begins, identify what change would count as useful, which unwanted changes would alter the balance of benefit and harm, who can observe each domain, and how observations will reach the prescriber. The target should be recognisable in everyday functioning, rather than a vague promise that the child will be "better". Carers, teachers, and the child may notice different things and may disagree.

Monitoring also tells the family that medication is revisable, not a verdict about the child. At each review, ask whether the treatment remains proportionate to the child's present needs and costs, not simply whether it has been taken.

RULE **Prescribe with a review question, not merely a review date.** The question links the original target, the observations that answer it, and the decision that will follow. A date without this structure easily becomes a refill encounter; a defined question makes it a clinical reassessment.

A useful record separates observation from interpretation. Document the account of participation, distress, behaviour, or functioning with its informant and setting, then state whether the pattern suggests benefit, intolerance, a contextual change, or inadequate information. This prevents the loudest informant from becoming the sole source of truth and makes the reasoning behind a treatment change transparent.

8.2 Build the monitoring plan before treatment begins

Pre-prescription assessment should produce a baseline that can be compared with later observations. The baseline is not an attempt to measure every possible outcome. It is a disciplined description of the presenting difficulty, the child's current functioning, relevant physical context, concurrent treatments, practical capacity to follow the plan, and the family's principal concerns. When baseline information is thin, later claims of improvement or deterioration are easily distorted by expectation, crisis resolution, school changes, or ordinary developmental variation.

The plan should state who will contact whom if the family is worried, what information should be brought to review, and what changes warrant earlier assessment. Families often interpret a prescription label as a complete treatment plan. Explain that medicines are part of care and that psychological, educational, and family interventions may remain essential. Their coordination is part of safe prescribing.

- Define the treatment target in language the family and child can recognise.
- Identify the settings and informants most likely to observe change.
- Record the child's starting physical and psychological state in clinically useful terms.
- Agree how benefit, burden, adherence, and uncertainty will be discussed at review.
- Document the contingency plan if concerns arise before the planned contact.

GOOD TO REMEMBER

The child's account is data, not a courtesy. Even when the child cannot describe an adverse effect in clinical language, descriptions such as feeling unlike oneself, unable to join in, frightened, dull, or embarrassed can identify an important treatment burden. Ask in private where appropriate, then bring the child back into the shared discussion rather than treating the consultation as an adult conversation conducted over the child.

8.3 Review efficacy, burden, and physical change together

Follow-up should revisit the original target and ask what has changed in the settings where the difficulty mattered. Symptom change alone is insufficient. A treatment can alter a visible behaviour yet leave the child less able to learn, relate, play, sleep, or participate. Conversely, a family may initially report little symptom change while describing a meaningful improvement in

distress or functioning. The prescriber's task is to weigh the full pattern, rather than reward only the most easily counted outcome.

An established practice-parameter teaching account expects medication follow-up **at least several times per year** for pharmacological treatment, with adjustment directed to continuing effectiveness, dose optimisation, and clinically important adverse effects. This is a review-point principle, not a substitute for earlier contact when the clinical situation calls for it. Its source is historical guidance, so it should be understood as established teaching rather than represented as a current live standard.

At these contacts, **height, weight, blood pressure, and pulse** are assessed periodically. That cadence is stimulant-specific; other drug classes carry their own schedules. The wider review asks what has happened since the previous contact, what changed in the child's environment, whether the medicine is being taken as intended, and whether the family's understanding has shifted. Continuation is itself a decision requiring reasons.

Monitoring intensity should respond to uncertainty and vulnerability. It may need closer contact when the clinical picture is changing, the child or family reports a concerning change, a treatment is being altered, information from settings is conflicting, or reliable observation is difficult. That judgement is not a licence for indiscriminate testing. It is a requirement to match the review process to the question being answered and to explain the rationale to the family.

REVIEW DOMAIN	QUESTION FOR THE CLINICIAN	DECISION RELEVANCE
Target difficulty	Has the problem that justified treatment changed in the settings that matter?	Tests whether there is benefit worth retaining.
Function	Is the child more able to participate in ordinary roles and relationships?	Prevents a narrow focus on a visible symptom.
Burden	What unwanted experiences do the child and carers describe?	Clarifies tolerability and acceptability.
Physical observation	Are the relevant physical findings being reviewed over time?	Links safety monitoring to the prescribed treatment.
Understanding	Can the family explain the purpose and current plan in their own words?	Detects misunderstanding before it becomes non-adherence or conflict.

TRAP **Do not call a tolerated prescription an effective one.** Absence of an obvious adverse effect does not establish benefit, and a report of benefit does not remove the need to ask what has been lost or made harder. The examination answer should show that efficacy, function, physical observations, and the child's experience are reviewed together.

8.4 Drug-specific monitoring must remain drug-specific

The general framework should not blur medicine-specific risks into a generic promise that "monitoring was done". The clinician must know which concerns follow from the selected

medicine, why they matter for that child, and how a result will change management. The detailed metabolic monitoring schedule for antipsychotics in children is addressed under antipsychotics in children; it should not be reproduced as a general rule for every child receiving psychotropics.

Treatment choices for attention-related difficulties should be read with the ADHD and specific learning/communication disorders notes, while the childhood disorders themselves and the paediatric SSRI black-box warning are covered in the Child behavioural, emotional and other disorders notes. Cross-reference prevents a general monitoring section from becoming a substitute for indication-specific prescribing knowledge.

PITFALL

Copying a monitoring schedule between medicine classes can create false reassurance. A neatly completed form is not evidence that the relevant risk has been assessed. Record the medicine, the clinical question, the observation sought, and the action that would follow from a concerning finding.

8.5 Assent makes the child a participant in care

Child assent is the child's affirmative, developmentally meaningful participation in a proposed course of care. It is not identical to legal consent and should not be presented as if a child's agreement can settle every question of authority. Its clinical value is substantial: it reveals what the child understands, corrects adult assumptions, permits discussion of fears and practical barriers, and makes it more likely that the child will report benefit or harm honestly.

Adapt the explanation to the child's language, maturity, emotional state, and ability to ask questions. The child should hear the treatment's purpose, what experience should be reported, what choices are open, and what will happen next. Do not ask "Do you agree?" before the child has been enabled to understand. Refusal deserves exploration: it may reflect fear, misinformation, an adverse experience, family conflict, or a concern adults have missed. Listening does not mean that every refusal determines the outcome, but dismissing it damages safety and alliance.

Assent must be revisited. A child who initially accepted a plan may understand it differently after experiencing treatment. Conversely, a child who was fearful at the outset may develop trust after a careful explanation and review. Revisiting assent is particularly important when the treatment purpose, burden, or family circumstances change. The record should show what was explained, how the child responded, questions raised, and how those questions influenced the plan.

8.6 Indian ethics guidance: a useful analogy, not the clinical statute

IN INDIA

The **Indian Council of Medical Research framework** cited here governs biomedical research involving children. It is useful by analogy when teaching how assent differs from parental permission, but it is not a clinical-consent statute. Do not convert a research-ethics age framework into a rule about clinical legal capacity. Statutory capacity, minor-treatment provisions, and forensic questions belong to the Mental health legislation and forensic psychiatry notes.

Within that research-ethics framework, the method of assent changes with the child's age. The table gives the framework once, because its value in clinical teaching is conceptual: the form of the conversation should develop, while parent or legally authorised representative involvement remains central. It should never be quoted as though it supplies the law of treatment consent.

CHILD'S AGE IN THE RESEARCH-ETHICS FRAMEWORK	ASSENT OR PERMISSION DESCRIBED	CLINICAL TEACHING USE
Under 7 years	Parental consent alone is described as sufficient.	Explain care in a manner the child can receive; do not mistake this research rule for clinical law.
7 (84 months) to 11 years	**Oral assent** is obtained with the parent or legally authorised representative present.	Use an understandable conversation and preserve the child's opportunity to respond.
12-18 years	**Written assent** is required.	Invite fuller participation while retaining the distinction between assent and legal authority.

The clinical conversation should remain respectful even where the legal analysis lies elsewhere. There is no therapeutic advantage in treating a child as a passive object of adult permission. The psychiatrist can be clear about the limits of decision-making while still giving the child privacy for questions, acknowledging ambivalence, and making the plan intelligible enough for the child to recognise when something is wrong.

8.7 Parental involvement should match the decision and its risk

The same research-ethics guidance frames **parent or legally authorised representative consent** in relation to the degree of risk. It says that consent from **one parent or legally authorised representative** may generally be sufficient for research involving minimal or low risk, while consent from **both parents** may be needed where research involves more than minimal or high risk. This is a risk-sensitive ethics framework, not a clinical rule that substitutes for applicable law or local institutional policy.

Its useful clinical lesson is that parental involvement should not be reduced to collecting a signature from whichever adult is present. Establish who cares for the child, whether disagreement affects the plan, whether the accompanying adult understands the information, and whether a broader conversation is necessary for safe follow-through. In conflict, do not recruit the child as an ally against a parent. Clarify the rationale, hear concerns, identify immediate risks, and seek the appropriate route when authority is uncertain.

- Separate the child's wishes from the legal question of who may authorise treatment.
- Separate parental disagreement from evidence about benefit and burden.
- Separate an urgent clinical need from the convenience of obtaining agreement.
- Document uncertainty about authority rather than concealing it in a generic consent entry.

MNEMONIC

Hear, Explain, Agree, Review

Hear the child and carers; **Explain** the target and foreseeable burden; seek meaningful **Agree**ment within the appropriate authority structure; and **Review** the decision as treatment unfolds. This is a consultation spine, not a claim that assent replaces consent.

Monitor the medicine, the child's functioning, and the family's understanding; consent is a continuing clinical conversation, not a form completed before treatment begins.

9 · Off-label prescribing, dosing principles and start-low go-slow in children

Why it matters clinically. Prescribing for a child is not a miniature version of prescribing for an adult. The diagnostic formulation may be clear, yet the prescriber still has to decide whether the proposed use is authorised for that age and indication, whether the expected benefit is meaningful to this child, and how to introduce treatment without mistaking an adverse effect, a developmental change, or a change in the home environment for drug response. These decisions are especially visible when a medicine is used **off-label**.

Off-label prescribing is a practical reality in Indian child psychopharmacology. It is neither automatically poor practice nor a substitute for reasoning. It means that the intended use does not match some part of the approved product information, such as the age group, indication, formulation, route, or dose. The clinician's task is therefore to make the mismatch explicit, decide whether it is justified for the individual child, and build a cautious plan around it. This fragment concerns that reasoning and the discipline of *start low, go slow*; disorder-specific regimens belong in the relevant disorder chapters.

9.1 Off-label use: a prescribing status, not a verdict

An off-label prescription is best understood as a description of the relationship between a proposed prescription and its label. It does not establish that the medicine is ineffective, unsafe, experimental, or negligent. Equally, the absence of a matching label must not be treated as a licence to prescribe casually. The label remains important because it records the regulatory indication, formulation, precautions, and population for which approval was granted. Clinical reasoning asks a different but connected question: whether the expected balance of benefit and harm is acceptable for this child, in this context, with this plan for review.

RULE **Off-label prescribing requires a clearer rationale, not a lower standard of care.** State the target problem, explain why the proposed use is reasonable, use the smallest prudent starting exposure, and arrange review that can detect benefit and harm.

For examination answers, the useful distinction is between **regulatory indication** and clinical indication. The former is a statement in authorised product information. The latter is the problem the psychiatrist is trying to treat after assessment. They often overlap, but they are not

interchangeable. A good answer avoids claiming that a label decides all clinical questions; a poor answer implies that a label is irrelevant once a clinician is confident.

QUESTION BEFORE PRESCRIBING	LABEL-ALIGNED USE	OFF-LABEL USE
What must be checked?	That the product and intended use match.	Which part of the proposed use differs from the label.
What must be documented?	The clinical target and review plan.	The clinical target, the rationale for the mismatch, and the review plan.
What must be discussed?	Expected benefit, unwanted effects, and practical use.	The same matters, plus the meaning of off-label use and uncertainty.
What changes the decision?	Benefit, harm, and whether the target remains relevant.	The same factors, with particular attention to whether the rationale remains sound.

OFF-LABEL	LABEL	TARGET
PRESCRIBING STATUS	CHECK BEFORE USE	DEFINE BEFORE TITRATION

9.2 The Indian regulatory context

IN INDIA

The CDSCO registry includes **atomoxetine** capsules for psychiatrist-directed treatment of attention deficit hyperactivity disorders. The same entry directs attention to **growth and weight** during long-term therapy. This is a concrete reminder that a paediatric psychiatric approval can exist, while the prescriber must still verify the current Indian information for the exact medicine, formulation, age group, and intended use. For disorder-specific treatment, see *the ADHD and specific learning/communication disorders notes*.

The available Indian inpatient evidence also cautions against pretending that off-label status is unusual. In a prospective Indian tertiary-care inpatient study, **1152** of **1645** prescribed medicines were classified as off-label, amounting to **70%**. This is general paediatric evidence, not a psychotropic-specific rate, so it should not be quoted as though it measured child psychiatric prescribing. Its teaching value is narrower and useful: off-label status is common enough in paediatric medicine that clinicians need a disciplined method rather than reflexive reassurance or reflexive refusal.

PITFALL

Do not infer an Indian paediatric approval from an overseas label or from a medicine's familiarity in practice. Approval is product- and use-specific. A copied prescription may look routine while its intended age, formulation, or indication has never been checked against the product information being used.

9.3 Making an off-label decision defensible

A defensible decision starts before the prescription. The child needs a formulation that identifies the problem to be changed and separates it from difficulties better addressed by psychological intervention, school support, parent work, environmental modification, or treatment of a physical contributor. Medication becomes difficult to evaluate when it is asked to solve an undefined cluster of behaviour, distress, family conflict, and educational strain. The more uncertain the target, the less interpretable the subsequent response.

The intended outcome should be observable. It may concern a symptom, a functional impairment, a pattern reported by caregivers, or a difficulty seen across settings. The wording should allow the family and clinician to recognise improvement without retrospectively redefining success. It should also name the adverse effects or clinical changes that would make the plan unacceptable. This is not a demand for rigid measurement in every consultation; it is a protection against the common drift in which treatment continues because nobody has decided what would count as benefit.

Next, consider alternatives honestly. The question is not whether medication can possibly be helpful, but whether it is the most proportionate next intervention. An off-label decision is stronger when the assessment has considered non-pharmacological options, when the proposed medicine has a credible role for the target problem, and when delay or non-treatment also carries a recognisable burden. This reasoning should be documented in clinical language, not as a defensive recital. A note that records the target, why the chosen option was selected, and the review plan is more useful to the child and the next clinician than a label alone.

- Specify the target problem and the setting in which change should be noticed.
- Check the current product information and record why the proposed use is appropriate despite any label mismatch.
- Agree on the observations that will count as benefit, harm, or need for change.

Communication with the parent or caregiver should be direct. Explain that the intended use is off-label, what that means in plain language, what is known and uncertain in the individual decision, and what review will look like. The child should be included in the discussion in a developmentally appropriate way. Detailed consent and assent practice, as well as the general monitoring framework, are addressed in the child psychopharmacology section on monitoring and consent; they should not be reduced to a signature obtained after the decision is already made.

TRAP **“Off-label” does not mean “off-evidence,” and “commonly used” does not mean “automatically appropriate.”** Candidates lose the clinical point when they answer only with regulatory language. The examiner is looking for an individualised indication, a transparent discussion, cautious dosing, and review.

9.4 Start low, go slow: what the phrase actually requires

Indian inpatient evidence shows why off-label status should be approached as a familiar paediatric prescribing problem rather than a reason to abandon judgement. Dose titration in children is a planned clinical experiment, not a race to a familiar adult dose. “Start low” means choosing a conservative initial exposure that permits early tolerability to be observed. “Go slow” means making measured adjustments only after there has been enough opportunity to understand the direction of change. The phrase is often repeated as a slogan; its practical value lies in the safeguards it imposes on interpretation.

At the outset, record the child's current symptoms, daily functioning, sleep, appetite, behaviour, physical complaints, concurrent medicines, and relevant medical history. The point is not to create an exhaustive checklist detached from the proposed medicine. It is to establish a baseline against which a new change can be judged. Without a baseline, irritability, fatigue, reduced appetite, activation, sedation, or a shift in behaviour may be attributed to the drug merely because the timing is convenient. The reverse error is equally hazardous: a genuine adverse effect may be dismissed as the child's usual presentation.

Titration should proceed with a single clearly interpretable change whenever feasible. If several interventions, doses, routines, and school responses are altered together, later improvement or deterioration has no clear owner. A paced plan also gives families time to notice changes that do not emerge in the consulting room. Caregiver reports, the child's own account where possible, and information from the relevant setting should be brought together, not used competitively. Disagreement is often clinically informative: it may reveal that benefit is context-bound, that harm occurs at a particular time, or that the treatment target was too broad.

The prescriber must remain willing to pause, reduce, stop, or rethink. A dose increase is not the default response to partial improvement. Before changing the dose, ask whether the target is genuinely improving, whether the adverse-effect burden is acceptable, whether adherence and administration are reliable, and whether the formulation remains correct. If the signal is unclear, greater exposure may magnify confusion rather than improve care. If the signal is unfavourable, a calm reassessment is more competent than persevering until the treatment appears to have been “adequately tried.”

GOOD TO REMEMBER

Slow titration is not therapeutic passivity. It is an information-gathering strategy. Each interval should answer a clinical question: is the target changing, is the child tolerating treatment, and does the next adjustment still make sense?

MNEMONIC

LABEL

Look at the label, define the **A**im, establish a **B**aseline, **E**scalate cautiously, and **L**isten at review. The mnemonic is a sequence for a safe prescribing conversation, not a substitute for a formulation.

9.5 Reviewing response without confusing noise for effect

Review is where the quality of the original prescription becomes visible. Revisit the target in the same words used at baseline. Ask what has changed in the child's experience and functioning, what others have observed, and whether the anticipated burden of treatment has appeared. A broad question such as “better?” often produces a broad answer. More useful questions connect to the agreed target: what is easier, what is unchanged, what has become harder, and when are the changes noticed?

Interpret change in context. A new routine, a school transition, an acute stressor, altered sleep, inconsistent administration, or a concurrent intervention can all affect the apparent response. This does not make medication assessment impossible. It means the clinician should resist premature certainty. Where uncertainty persists, simplifying the plan may be safer than layering new medicines or increasing an unclear dose. The child is not a failed trial because the first plan did not yield a clean answer; the formulation may need revision.

Long-term prescribing needs periodic reconsideration of continuing need. The original target may have changed, development may have altered the risk-benefit balance, or non-pharmacological supports may now carry more of the therapeutic work. Continuation should therefore be an active decision, not a consequence of repeated dispensing. The clinician should preserve a clear account of current benefit, current harm, and the reason to continue, alter, or withdraw treatment. This is especially important when care is transferred between services.

- Compare the current presentation with the original target, baseline, and anticipated unwanted effects.
- Check whether intervening contextual changes explain part of the apparent response.
- Decide explicitly whether to continue, modify, pause, stop, or reformulate the plan.

9.6 How to write and answer the principle

In a short answer, begin by defining off-label use as a mismatch with approved product information rather than calling it illegal or experimental. Then state that it can be clinically justified when the indication is individualised, the rationale is documented, the parent or caregiver is informed, and follow-up can detect benefit and harm. Add the dosing principle: begin conservatively, adjust gradually, and make each change interpretable. Close by stating that a child must be treated as a developing person in a family and service context, not as a smaller adult receiving a scaled-down prescription.

> Off-label prescribing in children is justified by an explicit individual rationale, transparent discussion, conservative initiation, gradual titration, and review against a pre-defined target.

Assessment and rating tools

10 · Principles of child psychiatric history and examination

The central task is to turn an account of a child into an account of functioning. A child psychiatric assessment is not a compressed adult interview and not a catalogue of symptoms reported by an accompanying adult. It asks what the child is able to do, communicate, tolerate and negotiate in ordinary relationships, and how that pattern alters across settings and over time. The examiner must therefore make the child visible without treating the parent, school or wider context as background noise.

The marks in this area reward method. A good answer shows how the clinician obtains a reliable account, observes the child directly, and reconciles apparent disagreement without prematurely converting it into a diagnosis. The core work is **a paired clinical frame**: **two** components, history-taking and the mental status examination, carried out as parts of one assessment rather than as separate rituals.

History	Mental state	Collateral
FUNCTION IN CONTEXT	DIRECT OBSERVATION	FUNCTION ACROSS SETTINGS

10.1 The assessment stance

Begin by deciding what question the referral is asking, while retaining enough breadth to discover that the question may be misplaced. The presenting concern is useful because it identifies distress, urgency and the family's explanatory model. It is not a diagnosis, and it should not dictate the sequence of the interview. The clinician needs a formulation-oriented account: the current difficulty, its context, the child's developmental capacities, relationships, functioning, strengths and risks. This is a clinical map, not an invitation to rehearse the disorder chapters.

History and examination proceed simultaneously. A caregiver's description of avoidance, for example, becomes more meaningful when the child's approach to the room, proximity seeking, speech, play, posture and response to the examiner are observed. Conversely, a striking behaviour in the room should be held as a sample, not promoted immediately to a trait. Children may be tired, frightened, oppositional, ill, overcontrolled, unfamiliar with the language of the interview, or responding to a tense interaction between adults. Good assessment makes room for these possibilities before assigning meaning.

RULE **Assess the child in development, relationship and setting, not as a symptom list detached from context.** The history supplies pattern and meaning; the examination tests how that account appears in the present encounter.

Consent, assent, confidentiality limits, safeguarding responses, formal risk procedures and diagnostic formulation require their own fuller treatment elsewhere in this chapter. Here, the interviewing discipline is simpler and more exacting: explain the purpose of the meeting in language the child can use, preserve respect for privacy without promising secrecy that cannot be

kept, and be clear with caregivers about when separate conversations are helpful. Do not make the child a passive object of adult testimony.

10.2 Building a history that explains development

A chronology alone does not constitute **developmental history**. The clinician elicits what happened in development and asks what those events came to mean to the child and family. The same developmental fact may be experienced as ordinary variation, a source of parental anxiety, a conflict within a family, a marker of loss, or a reason a child has repeatedly been treated as incapable. Those meanings influence expectations, attachment, school communication and help-seeking. They can also alter what caregivers notice and how they describe it.

The history should connect early functioning to the current problem without treating childhood as a deterministic preface. Ask about the child's usual ways of regulating emotion and behaviour, communicating needs, responding to change, relating to familiar and unfamiliar people, learning and managing daily demands. Clarify the sequence: what was present before the concern, what changed around its emergence, and what maintains or relieves it now. Where the history is uncertain, record uncertainty. Retrospective accounts are valuable clinical data, but their confidence, perspective and emotional charge matter.

Family accounts should be heard for both content and process. Who speaks first, who corrects whom, whose worries are minimised, and how the child responds while adults discuss them may illuminate the current relational field. This is not licence to infer hidden motives from a single consultation. It is a reason to seek examples, compare accounts and distinguish observed behaviour from interpretation. A respectful interviewer can ask a parent what a difficult behaviour means to them, then ask the child what the same situation feels like, without making either party the unreliable witness.

- Anchor each concern to a concrete situation rather than accepting a global label such as "difficult" or "lazy".
- Separate onset, course, triggers, consequences and attempted responses, while leaving room for uncertainty.
- Document strengths and effective relationships, because they identify leverage for care as well as resilience.

> **GOOD TO REMEMBER**
> When a caregiver reports a behaviour, ask what happens immediately before it, what the child does next, how others respond and what changes afterwards. This moves the history from a moral description to an observable clinical sequence without importing a diagnosis.

10.3 Collateral information and discrepancy

Multi-informant assessment is necessary because children function in relationships and settings that no single observer can fully represent. For most children, work from at least **three** essential sources: the parent or other primary caregiver, the child and the school. Each source has a different observational position. The child can report subjective experience and meanings that

adults do not see. Caregivers provide longitudinal knowledge and accounts of home life. School information describes demands, peer context and functioning outside the family.

Collateral is not a vote in which the majority account wins. A difference between home and school may reflect variation in structure, expectation, language, relationships, sensory load or opportunities for support. A child may also disclose selectively, or an adult may have limited opportunity to observe a particular domain. The clinical task is to ask what the discrepancy tells us about conditions under which the difficulty appears, improves or becomes invisible. Treating disagreement as error too early discards useful information.

Seek information in a focused, proportionate manner. State what question the school is being asked to help answer and distinguish facts, examples and interpretations in the record. Agency material and reports from other family members may add context, but should not become a substitute for meeting the child or listening to the primary caregivers. In India, school information may be especially uneven: attendance, language of instruction, class size, family mobility and access to trained staff can affect both what is observed and what can be communicated. The response is to interpret the limits of the collateral, not to assume it is useless.

SOURCE	DISTINCT CONTRIBUTION	CLINICAL QUESTION
Child	Experience, meanings and preferred ways of communicating	What is happening from the child's point of view?
Caregiver	Developmental course and daily context	How has the pattern changed and what surrounds it at home?
School	Functioning under educational and peer demands	What changes in another structured setting?

IN INDIA

School collateral may need practical adaptation. A written report is useful when feasible, but a focused conversation with the person who knows the child's day-to-day functioning can be more informative than a generic certificate. Preserve the distinction between a teacher's direct observations and conclusions about the child.

TRAP **Do not call discrepant informants "unreliable" simply because their accounts differ.** The discrepancy may locate the setting, relationship or demand in which the problem is expressed. It requires enquiry, not arithmetic.

10.4 The child mental status examination

The **developmentally adapted mental status examination** begins before formal questions. Observe physical appearance, the manner of relating to the examiner and caregivers, and the ease or difficulty of separation. Note affect and mood, orientation, and motor behaviour, including activity level, coordination, neurological soft signs, dominance and the presence of tics or stereotyped movements. These observations must be described in neutral, behaviourally

anchored language. “Stayed close to caregiver and answered after looking towards her” is more useful than a global claim about attachment or temperament.

The examination then explores thought content and form, speech and language, overall intellectual functioning, attention, memory, neurological functioning, judgment and insight. It also records the child’s **preferred mode of communication**. For some children, play, drawing or direct conversation may make different parts of their experience accessible. The point is not to force every child through an adult verbal template. It is to create enough access to assess what can be observed and communicated, and to state the limits of that access.

Questions should be concrete enough to be understood and open enough to reveal the child’s organisation of experience. Ask for examples and clarify the child’s language before translating it into psychiatric terminology. Evaluate attention in relation to the task, the room and the interaction, rather than treating a brief lapse as a stable conclusion. Similarly, assess apparent insight in the light of the child’s developmental capacity and the information they have been given. Silence, limited language, avoidance or playful deflection can be meaningful, but none is self-interpreting.

- Record behaviour, speech, affect and engagement as observed, then separate the clinical inference from the observation.
- Use the child’s most accessible communication channel while preserving the clinical question.
- State when an item could not be assessed adequately, rather than converting incomplete examination into a negative finding.

PITFALL

A brief, highly structured consultation can make a child appear more settled or more inhibited than in ordinary life. Do not treat the examination as a performance test that overrules the longitudinal history. Integrate it with collateral and revisit uncertain findings.

10.5 Integrating observation without over-reading it

The child’s behaviour in the room is relational data. It is shaped by the examiner’s manner, the caregiver’s presence, the sequence of the visit, the unfamiliar setting and the child’s understanding of why they have come. A calm child may be containing distress; an active child may be engaging, avoiding, testing boundaries or reacting to an overstimulating room. The answer is not to abandon observation, but to make the observation precise and test alternative explanations through gentle changes in approach.

Examination and history should therefore be written so that another clinician can see the bridge between them. Describe the source, the setting, the observation and the inference. If the child’s account and caregiver’s account diverge, say how each was obtained and what further information would help. A formulation may remain provisional while the assessment continues. That is not indecision. It is appropriate calibration when the available data do not yet support a firm conclusion.

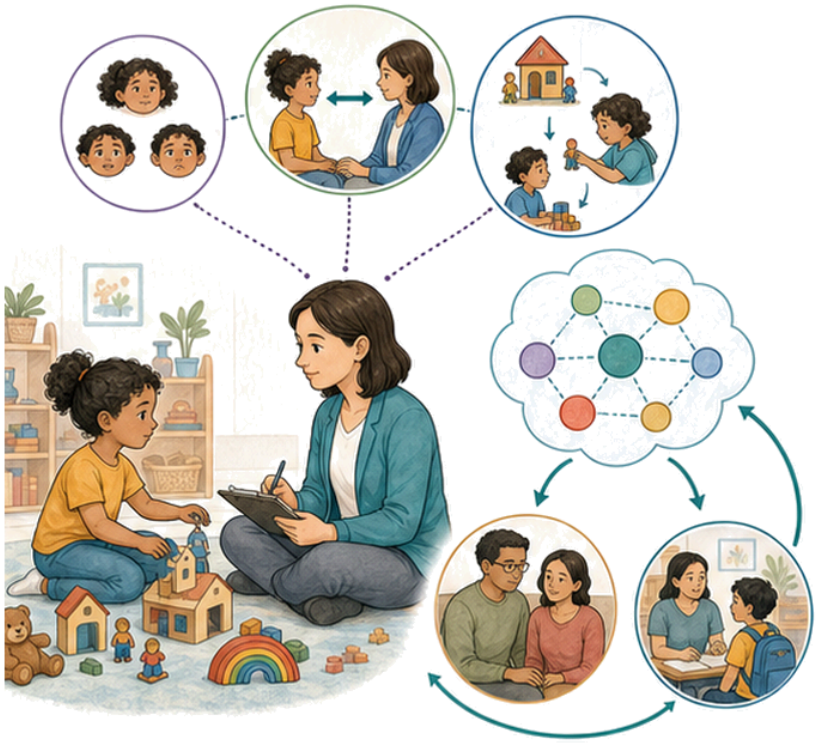
For developmental expectations and milestones, use the Normal child development and milestones notes. For the childhood disorders themselves, use the Child behavioural, emotional and other disorders notes. For intellectual disability and autism-related assessment, use the Intellectual disability and autism spectrum disorder notes. Standardised developmental, cognitive, adaptive, behavioural and neuropsychological instruments are addressed in their respective assessment sections; they complement, rather than replace, the child developmental history and mental-state examination.

MNEMONIC

Child, Caregiver, Classroom

Use this as a retrieval cue for the core sources of an assessment: hear the child's account, establish the caregiver's longitudinal account, and obtain the school view of functioning in another setting. The cue is a reminder to compare perspectives, not a licence to collect generic reports.

10.6 Documentation and the examination answer



A defensible record makes the reasoning inspectable. It identifies who provided information, distinguishes reported material from direct observation, preserves relevant examples and records limitations. It should show the relationship between developmental history, present functioning and the mental state examination without manufacturing certainty. The record is strongest when it explains why a particular question was asked and how the answer altered the next clinical step.

In a written answer, begin with the need for developmental, contextual and multi-informant assessment. Then set out the history in an organised sequence, describe the directly observed mental state in developmentally appropriate terms, and finish by showing how discrepancies will be reconciled. Avoid listing adult mental-state headings without adaptation. Avoid writing an instrument catalogue where a clinical examination has been asked for. The candidate who demonstrates method, rather than reciting labels, shows that assessment can guide treatment and referral.

A child psychiatric assessment is credible when developmental history, direct mental-state observation and collateral accounts are integrated without allowing any single source to stand for the child.

11 · Play assessment and interviewing children

Play is clinical material, not a diversion. In an interview with a child, direct questioning can produce compliance, silence, borrowed adult language, or a rapid shift away from what feels unsafe. Play creates a shared activity in which the clinician can listen to what is said, watch how it is said, and notice what happens when the child has some control over the pace and distance of contact. Used well, it enlarges the interview. Used carelessly, it turns an ordinary toy interaction into a premature story about the child.

- Shared activity
- Observe
- Listen
- Form a hypothesis
- Corroborate
- Do not over-interpret

Fig 24.6 A play-based interview gives the child control over pace and distance while the clinician observes communication, affect and relationship. Play generates hypotheses that require corroboration; it is not a disguised test or a license for symbolic over-interpretation.

The marks lie in understanding this distinction. Play assessment is neither a disguised intelligence test nor a treatment session. It is a developmentally adjusted way of obtaining history and mental-state material while preserving curiosity about alternative explanations. The general child psychiatric history, examination, collateral information and multi-informant formulation belong with the general assessment framework. This section concerns the interview encounter itself: how to make room for play, observe it, and translate observations into hypotheses that require corroboration.

11.1 The purpose of a play-based interview

Children often communicate experience through action before they can organise it into an account for an adult. The clinician therefore treats play as a medium that can carry themes of threat, comfort, power, separation, rivalry, loss, bodily concern or mastery, without assuming that any single theme is a literal report. **Imaginative play** using puppets, small figures, or the clinician

as a participant can offer inferential material about the child's concerns, perceptions and ways of regulating affect and impulse.

This is especially useful when a question is emotionally loaded. Rather than pressing for an explanation, the clinician may offer an ordinary shared activity and allow the child to decide whether a story, scene, game or silence develops. The gain is not access to a hidden truth on demand. It is the chance to observe the child's manner of approaching a difficult area: whether the child can initiate, sustain, modify, share or abandon an imagined situation; whether feelings are named, enacted, avoided or rapidly displaced; and whether the adult is invited into the child's world or kept at a fixed distance.

Play has a relational function as well as an observational one. A child who has little trust in adults may first need to discover whether the interviewer can be interested without taking over, can tolerate pauses without filling them, and can set a limit without becoming punitive. The clinician's task is to offer structure sufficient for safety while leaving the child enough agency to show how contact is managed. This is interview technique, not play therapy. The purpose remains assessment and formulation, with the child's welfare taking precedence over the production of material.

RULE **Adapt the interview method to the child, rather than forcing the child into the clinician's preferred method.** Technique should be tailored to **developmental level**, **cognitive level**, **linguistic level**, the emotional difficulty of the topic, and the available **rapport**. A playful invitation may be useful in one encounter and intrusive in another.

11.2 Preparing the encounter

A useful play interview begins before any toy is touched. The room should be calm enough for conversation and permissive enough for the child to explore without the clinician repeatedly issuing prohibitions. Materials should be ordinary, durable and open to more than one use. The aim is not an impressive collection but a setting in which the child does not need special skill, prior knowledge or adult permission to begin. Materials that are too elaborate can turn the encounter into a performance; materials that demand a correct answer can recreate the pressure of school.

The opening should be plain and honest. Explain who you are and what will happen in language the child can follow. State that the child may talk, draw, play, ask questions or say that something is difficult. Do not promise secrecy that cannot be maintained, and do not announce that play will reveal what the child is unable to say. Such statements burden the child and distort the clinical relationship. A brief period of shared orientation lets the clinician observe spontaneous choice without making the child feel watched for a right response.

The caregiver's place requires deliberate management. A caregiver may help a child settle, provide essential context, or inadvertently answer every question. The clinician should neither exclude the caregiver reflexively nor allow the child's account to be overwritten. A separate space for each voice is often necessary. When the child is seen alone, the transition should be explained in a way that does not imply that either child or caregiver is under suspicion. Questions about safety,

confidentiality and separate interviewing are part of the general assessment framework and must be handled within local clinical and safeguarding practice.

- Begin with a low-demand invitation rather than a request for a problem narrative.
- Follow the child's level of engagement, but retain a clear clinical purpose.
- Close predictably, giving the child time to shift back from the activity.

IN INDIA

Language choice is often the first clinical adaptation. A child may understand the language used by adults in the family yet express play, emotion and peer experience more naturally in another language. Clarify the child's preferred language for ordinary conversation and avoid treating a quiet response in an unfamiliar language as evidence of limited feeling or limited thought. When interpretation is needed, keep questions short, allow the child time to respond, and record the limits this places on inference.

11.3 Observing play without overreading it

The useful unit of observation is a pattern, not an isolated symbol. Notice the child's entry into play, selection and use of materials, capacity to generate ideas, response to novelty, flexibility when the scene changes, tolerance of frustration, and manner of involving the interviewer. Observe the emotional tone of the activity and its transitions. A child may appear cheerful while repeatedly arranging a controlling scenario; another may use a frightening story with evident enjoyment and imaginative flexibility. Neither observation explains itself.

Content matters, but form often provides the safer starting point. Is the play exploratory or restricted? Is it reciprocal, solitary, controlling, repetitive, hurried, frozen or readily abandoned? Does the child use pretend transformation, or insist that each object retain only its literal function? Does the child's narrative have continuity, or is it made of disconnected actions? The clinician should describe first and infer second. A note that records what happened can be reconsidered against history and collateral; a note that records only a conclusion cannot.

OBSERVATION	CLINICAL QUESTION IT RAISES	APPROPRIATE NEXT STEP
Choice of a familiar activity	What does the child use to establish safety and control?	Join briefly, then see whether the child can extend or vary the activity.
Repeated theme in a story	Is the theme meaningful, rehearsed, situational or prompted by the setting?	Ask open questions and compare with the child's account and collateral.
Difficulty sharing the activity	How does the child manage reciprocal attention and adult participation?	Offer a modest invitation rather than forcing cooperation.
Rapid escalation when frustrated	How are affect and impulse managed in the moment?	Set a calm limit and observe recovery, repair and need for support.
Very limited, concrete and noninteractive imaginative play	Does the form of play raise a developmental hypothesis?	Document the observation and integrate it with the broader developmental assessment; this pattern may suggest **autism spectrum disorder**, but is not diagnostic by itself.

Description protects against projection. Children's play readily activates the clinician's own associations. A dramatic scene may tempt the clinician to infer trauma, aggression or family conflict. Those are hypotheses, not findings. The more emotionally striking the scene, the more important it is to ask whether the theme arose spontaneously, whether it recurs across contexts, whether the child can reflect on it, and whether independent history supports the concern. Silence, avoidance and change of subject may themselves be meaningful, but they are also ordinary responses to an unfamiliar adult, fatigue, shame or uncertainty about what is expected.

PITFALL

Do not translate a toy, drawing or narrative role into a one-to-one diagnostic or forensic meaning. A child may choose a frightening character because it is familiar, powerful, amusing, recently seen, or simply available. The clinical value lies in the whole interaction, its form and affect, and its fit with other evidence.

11.4 The clinician's use of self

The interviewer is part of the play field. Children may invite the clinician to be a character, assign a role, test a rule, or ignore the invitation entirely. Participation can be useful if it follows the child's lead and remains light enough for the child to alter it. Taking over the plot, improving the child's story, teaching a moral, or repeatedly interpreting the scene shifts the task from observation to adult direction. The child then reveals how they respond to the clinician's demands, not necessarily how they play.

Comments should be simple, concrete and tentative. Reflecting an observable action, naming an evident affect, or asking what happens next keeps ownership with the child. Questions that demand explanation too early can collapse imaginative material into a test of verbal skill.

Likewise, excessive praise can make play performance-oriented. The clinician should be capable of waiting, of accepting a child's refusal to include them, and of returning to ordinary conversation when play does not become a useful medium.

Limits are clinically informative when delivered without humiliation. If materials are used unsafely or the child attempts to damage the setting, stop the act clearly and offer a permitted alternative. What follows may illuminate the child's response to frustration, but it must never be engineered as a provocation. The aim is not to expose a deficit. It is to maintain a setting in which the child can continue to engage and the clinician can observe regulation and repair.

GOOD TO REMEMBER

When a child does not play, do not make play the test. Sit alongside, use conversation or a neutral activity, and return to the invitation only if it fits the child's pace. Refusal may communicate discomfort with the setting, unfamiliarity with the materials, tiredness, fear of being judged, or a wish to preserve control. Record the context as carefully as the refusal.

11.5 From observation to clinical inference

Play observations become clinically useful only when they change the next question. A child who repeatedly separates figures may be asked, in an open manner, what happens when people are apart and whom the child misses. A child who makes every adult character controlling may invite questions about rules, conflict and safety. A child who cannot tolerate a change in the game may need a broader enquiry into flexibility across home and school. The inquiry remains open because the same play pattern can arise from many pathways.

Formulation should preserve levels of certainty. A descriptive level records the activity, speech, affect, reciprocity and regulation observed. A hypothesis level states what the pattern may mean. A verification level identifies what information is required before the hypothesis influences diagnosis, risk assessment or intervention. This discipline prevents play from becoming a privileged source that outranks the child's words, caregiver account, teacher information, developmental history or direct mental-state examination.

- Write observations in behavioural language before writing interpretations.
- Link an inference to the question it raises, rather than to a diagnosis it proves.
- Seek convergence across interview, collateral history and longitudinal observation.

TRAP **Do not treat play content as a projective key with a fixed meaning.** The classic error is to move from a striking scene to a categorical conclusion. Good assessment asks what else could account for the observation, then looks for convergence. Play can generate an important clinical question; it cannot settle one in isolation.

11.6 Interviewing across developmental capacities

There is no universally correct child interview format. The same child may need a different approach when discussing a pleasant activity, a school difficulty, a conflict at home or a frightening experience. The choice of method should be guided by the child's capacity to

understand the task, use language, sustain shared attention and tolerate the topic, as well as by the relationship established in the room. The relevant principle is flexible adaptation to the **emotional difficulty** of the topic, not a rule that younger children always play and older children always talk.

For a child who uses little verbal elaboration, the interviewer may alternate short questions with observation in a shared activity. For a verbally fluent child, play can still reveal the interpersonal style that a polished account conceals. For an adolescent, a direct conversation may be preferred, while a collaborative task or informal activity can reduce the intensity of sustained face-to-face questioning. The clinician should offer, rather than impose, a mode of communication. Respecting a child's preference does not mean abandoning difficult topics; it means approaching them in a way that preserves the possibility of honest engagement.

Developmental adaptation also means distinguishing inability from unwillingness. A child who cannot answer an abstract question may understand a concrete example. A child who appears oppositional may be confused by an adult's phrasing. A child who changes the subject may be protecting themselves from affect, but may also be responding to embarrassment or loss of attention. The clinician reduces these ambiguities through clarification, pacing and repeated observation, not by assuming a motive.

11.7 Documentation, boundaries and the limits of the method

Document the setting, who was present, the invitation offered, the child's response, the relevant sequence of play, verbal statements that materially altered interpretation, affective shifts, clinician interventions and the child's response to them. Separate observation from interpretation in the record. It is preferable to note that a child repeatedly placed figures apart and became quiet when asked about reunion than to write a diagnostic conclusion. The latter move prematurely converts an observation into a conclusion.

Play should not be used to obtain a disclosure by suggestion, to test an allegation, or to bypass established safeguarding procedures. When the interview raises concern about harm, the clinician must move from exploratory technique to a careful, non-leading and safety-focused response within the relevant protection pathway. The child's immediate safety and the integrity of any necessary assessment take precedence over completing a play narrative. Detailed abuse assessment and its psychiatric sequelae are addressed in the child-protection sections of this chapter.

Nor should the clinician infer that a child who plays freely has no distress, or that a child who does not play has a severe disorder. Play is one channel among several. Its greatest value is often modest but decisive: it shows the child's style of communication and regulation in real time, suggests questions that ordinary history-taking might miss, and helps the interviewer build enough trust for a fuller account. Its limitations are the same as its strengths: it is relational, contextual and therefore demands disciplined interpretation.

PLAY	FORM	PATTERN	CONVERGENCE
A MEDIUM FOR COMMUNICATION	MENTAL-STATE INFORMATION	BASIS FOR HYPOTHESIS	BASIS FOR CONFIDENCE

Use play to open and observe the child's world; use corroboration to decide what the observation means.

12 · Developmental and IQ tests (Binet, WISC, Malin, Bhatia, Seguin form board)

Why it matters clinically. A developmental or intelligence assessment is not a hunt for a single score. It is a disciplined way of describing how a child approached cognitive demands, where performance was relatively easier or harder, and how confidently the clinician can use that information in a formulation. In child psychiatry, the test result often changes the question being asked: whether a difficulty is best understood as globally low performance, an uneven cognitive profile, a language-mediated barrier, a problem of access to learning, a state effect, or a finding that needs further assessment. The useful report therefore connects the referral question to the conditions under which the child worked and to the limits of what the result can bear.

This child developmental and IQ battery comprises child intelligence measures and performance-based tasks. These are not interchangeable labels for the same activity. They differ in the demands they place on language, motor output, visual organization and cooperation. Test choice is consequently a clinical decision, not a ritual. Developmental screening, adaptive assessment, broad-band scales, projective methods and formal neuropsychological assessment have separate roles elsewhere in this chapter.

Question	Mode	Context	Use
WHAT DECISION NEEDS HELP	VERBAL OR PERFORMANCE DEMAND	CONDITIONS OF TESTING	NEXT CLINICAL STEP

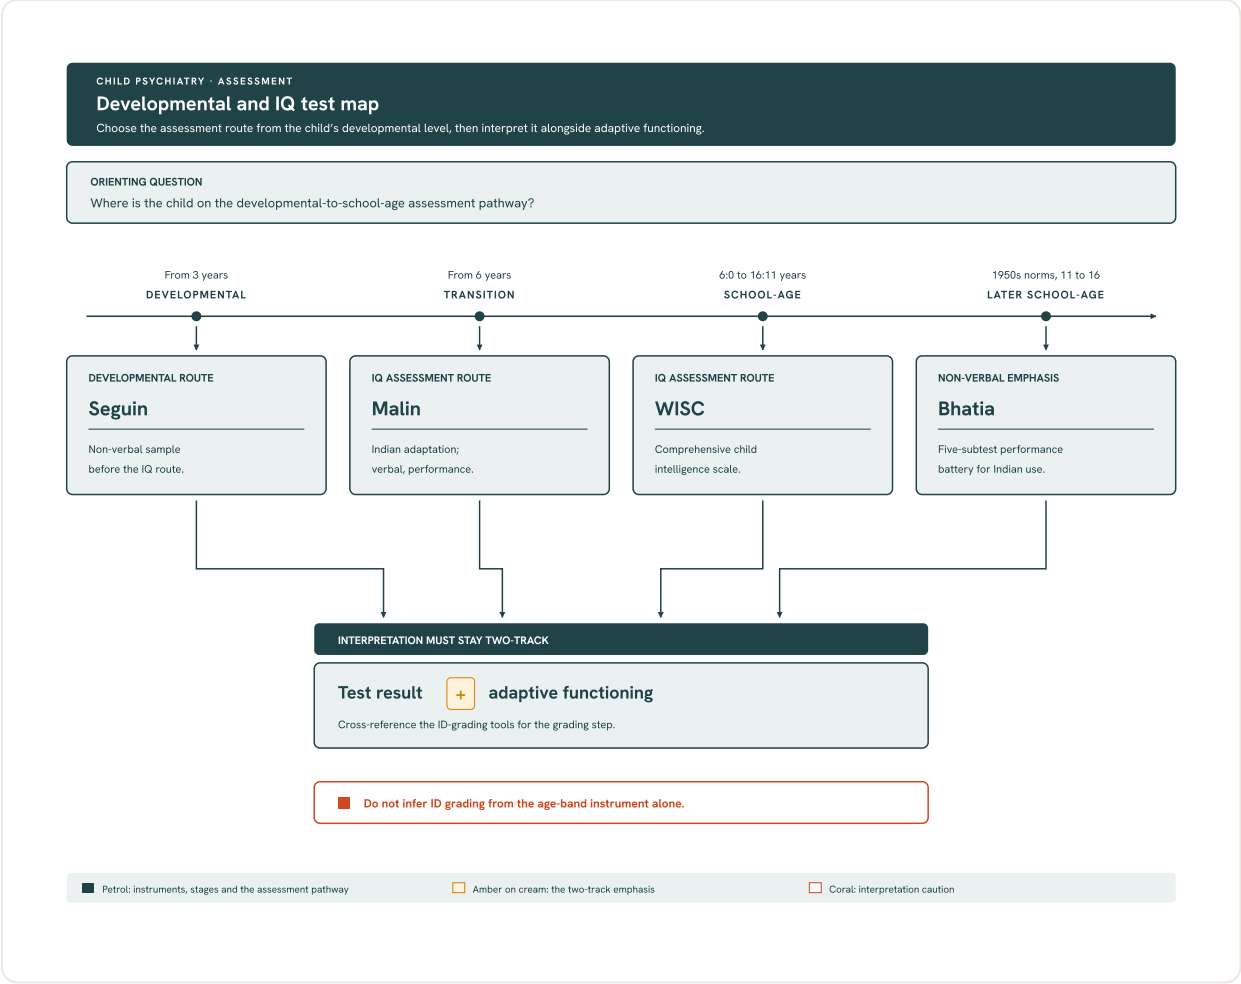


Fig 24.7. The child developmental and intelligence testing map, laid out by age band and by what each instrument is for. Choose the test by the question being asked; the intellectual-disability grading application of these instruments belongs to the intellectual disability and autism spectrum disorder notes and is cross-referred, not taught here.

12.1 What an intelligence test contributes

An intelligence test samples performance under structured conditions. Its value is not simply that it yields a summary estimate. The encounter makes visible the child's comprehension of instructions, pace of engagement, response to novelty, tolerance of correction, persistence, impulsive responding and use of help. These observations can qualify the interpretation more than a polished numerical statement ever can. A child who gives up after a first difficulty and a child who works slowly but methodically may arrive at superficially similar outcomes for very different reasons.

The report should distinguish an obtained test performance from an explanation for that performance. Low output can arise when the child did not understand the task, could not sustain engagement, was anxious, was affected by language mismatch, or had sensory, motor or educational barriers. Equally, an apparently adequate overall performance may conceal a clinically important discrepancy in how different kinds of demand were handled. The psychiatrist should ask what the test has actually sampled in this child, on this occasion, before deciding what it means.

That distinction protects the child from a common category error. Cognitive testing informs clinical judgement; it does not replace it. The result must sit beside the developmental account,

physical and neurological findings when relevant, schooling history, family context, and functional account from the adults who know the child. These surrounding data do not dilute the test. They give it a valid clinical home.

RULE **Interpret the child's way of working before interpreting the score.** A score becomes clinically meaningful only when the referral question, testing conditions, language demands and behavioural observations are made explicit.

12.2 Selecting a measure from the referral question

Begin by naming the decision that the assessment is meant to inform. A vague request for an "IQ test" invites an equally vague answer. A referral may instead concern a child whose spoken language makes verbally mediated work difficult, a child with limited opportunity to show classroom learning, a child with suspected uneven abilities, or a child whose engagement with formal tasks is uncertain. The clinician and psychologist should agree what information would move care forward and what the chosen procedure cannot answer.

The next task is to match the mode of assessment to the child rather than forcing the child to fit the instrument. Verbal demands, familiarity with the language of testing, manual dexterity, visual and motor coordination, fatigue, hearing or vision concerns, and the child's capacity to settle into a structured interaction all matter. This does not mean abandoning standardisation whenever a child is difficult to test. It means recording the circumstances faithfully and using any necessary caution in the conclusion.

- Specify the referral decision that the result is meant to inform.
- Tell the assessor about barriers that may prevent the child from showing usual abilities.

Performance-based tasks can be particularly informative where spoken responses give an incomplete picture. They are not, however, language-free truth machines. Understanding the demonstration, handling unfamiliar materials, tolerating timed or observed work, and organising action all remain part of the demand. The correct clinical question is therefore not whether one test is intrinsically fair, but whether its demands are sufficiently understood for the result to answer this referral question.

GOOD TO REMEMBER

Before requesting testing, state the clinical question in one sentence and tell the assessor about communication, sensory, motor, behavioural and school-access concerns. A better referral produces a more interpretable report and avoids treating the assessment as an administrative certificate.

12.3 A comprehensive child assessment

The **WISC-V, the Wechsler Intelligence Scale for Children, Fifth Edition**, is a comprehensive child intelligence assessment. The publisher's normative age range is **6:0-16:11 years**. Its clinical importance lies in the opportunity to examine performance across differently organised demands rather than reducing the encounter to one global label. That does not license the psychiatrist to

infer detailed cognitive strengths from a summary alone, nor to reproduce proprietary material in a case note or teaching answer.

When a report based on this assessment is available, read the narrative before the conclusion. Look for whether the child understood the task language, required repetition, rushed, sought reassurance, became frustrated, or showed marked variability in effort. Ask whether the child's educational and language background was compatible with the testing situation. A report that describes meaningful variation may guide the next clinical question, whereas a bare score without conditions of testing should be treated with restraint.

For the psychiatrist, the contribution is often relational as well as psychometric. The child's behaviour in an individual, structured encounter may illuminate a familiar difficulty that parents or teachers have described, but it should never be read as proof of a diagnosis by itself. Conversely, a cooperative testing session should not be used to dismiss difficulties reported in less structured settings. The clinical synthesis is stronger when test behaviour is treated as one sample of functioning rather than as a personality verdict.

TRAP **A comprehensive intelligence measure is not a diagnosis machine.** Candidates lose clinical precision when they convert an obtained result into a disorder label without considering language, learning opportunity, adaptive functioning, behaviour during testing and the reason for referral.

12.4 An Indian adapted child measure

Malin's Intelligence Scale for Indian Children is an Indian adaptation that assesses verbal and performance abilities. It is administered by a trained psychologist and is used from **6 years onward**. Its relevance is practical: an Indian adaptation is often encountered in clinical records and referral pathways, and the psychiatrist should be able to read its report without assuming that the name alone settles validity for every child.

An Indian adaptation does not remove the need for clinical attention to the child's actual linguistic, educational and sociocultural context. India contains wide variation in home language, medium of instruction, familiarity with formal testing and experience of school. The clinician should identify a mismatch rather than silently treating it as a child deficit. The report should make clear which language was used, whether translation or explanation was needed, and whether the observed performance reasonably reflects the child's capacity in the setting being assessed.

Verbal and performance information should be read as complementary descriptions of task performance. A difference between them is a prompt to enquire, not a self-contained explanation. Consider communication history, literacy exposure, schooling continuity, behaviour, motor competence and the family's account of everyday problem-solving. A single difference should not be converted into a sweeping statement about ability, motivation or family environment.

IN INDIA

Use the availability of an Indian adaptation as a reason to improve the assessment conversation, not to stop it. Record the language of testing, the child's medium of instruction and barriers to school participation. These details help the team decide whether the result is a sound estimate, a limited sample, or a signal that another approach is needed.

12.5 A performance battery: use and historical caution

Bhatia's Battery of Performance Tests of Intelligence is an Indian non-verbal, performance-oriented battery. Its named components are **five** subtests: **Kohs' Block Design, Alexander's Pass-along, Pattern Drawing, Picture Construction and Immediate Memory**. This makes the battery useful to recognise in Indian practice, especially when the child's performance on material-based tasks is clinically more accessible than a long verbally mediated exchange.

The attraction of a performance battery is understandable. It can offer a route into assessment when expressive language is limited or when a child is reluctant to engage in conversation. Yet performance tasks draw on more than abstract reasoning. The child must understand what is expected, coordinate perception and action, regulate pace and persistence, and work in the presence of an assessor. The psychiatrist should therefore use the result to sharpen the formulation, not to erase communication, motor or contextual difficulties from it.

The original standardisation was on Indian boys aged **11-16 years**. This historical fact has direct interpretive consequences. The clinician should not speak as if the original reference group automatically represents every contemporary child. If a report relies on the battery, ask which reference material and interpretive conventions were used, whether they fit the child before you, and what uncertainties the assessor has documented.

INSTRUMENT	CLINICAL CONTRIBUTION	INTERPRETIVE DISCIPLINE
Comprehensive child measure	Structured cognitive assessment	Read observed task behaviour and testing conditions with the report.
Indian adapted measure	Verbal and performance abilities	Attend to language and educational context.
Performance battery	Material-based, non-verbal approach	Do not mistake motor, organisational or comprehension demands for pure reasoning.
Form-board task	Rapid non-verbal performance sample	Use it as a focused sample, not as a complete account of intellect.

12.6 A focused early performance sample

The **Seguin Form Board Test** is a rapid non-verbal performance test that can be used from **3 years**. It samples motor dexterity, visuomotor coordination, spatial organisation, and the speed and accuracy of performance. This makes it clinically useful when the assessment needs a brief, concrete observation of how a young child approaches a structured material task.

The **form-board apparatus** uses differently shaped wooden blocks fitted into matching slots. The apparent simplicity is one reason it is easy to overinterpret. A child may struggle because of fine-motor difficulty, visual-perceptual difficulty, poor comprehension of the demonstration, reluctance to separate from a caregiver, impulsive placement, or difficulty sustaining the task. The observation of strategy matters: whether the child scans the board, uses trial and error, persists after an error, or abandons the task can be more clinically informative than a decontextualised label.

Its non-verbal form is a relative advantage, not an exemption from careful administration. Demonstration and rapport still matter; so do the child's visual and motor capacities. It is best understood as a focused performance sample within an assessment plan. It cannot independently settle broader questions about developmental level, educational need or intellectual functioning.

> **PITFALL**
>
> Do not reproduce test items, scoring rules or cut-offs in a clinical teaching note. Proprietary instruments require standardised administration and trained interpretation. The useful psychiatric record states the referral question, relevant conditions of testing, observed approach, report conclusion and its limits.

12.7 Observing the assessment, not merely receiving it

Psychiatrists often receive a report after the formal session rather than administering the measure themselves. That does not make the report a black box. A good discussion with the psychologist asks how the child entered the task, what forms of instruction were effective, whether the child was distractible or overcontrolled, and whether performance was consistent across the session. Such questions improve the clinical interpretation without asking the psychologist to disclose protected test content.

Behavioural observations should be described precisely and modestly. "Needed frequent encouragement" is an observation; "unmotivated" is an inference that may be unfair. "Asked repeatedly for the instruction to be restated" is useful; "poor intelligence" is neither an observation nor a formulation. This discipline matters especially when the assessment may influence educational planning, family expectations or access to supports.

Where there is a major discrepancy between the clinical picture and the test report, do not choose the more convenient version. Re-examine whether the referral question was correct, whether the child was able to show their abilities in the testing context, and whether another assessment modality is needed. A discrepancy is often the important finding. It directs curiosity towards the conditions under which the child does and does not function well.

12.8 Writing a defensible psychiatric formulation

A concise formulation after cognitive testing has several jobs. It identifies the source and purpose of the assessment, describes the adequacy of engagement, states whether language, sensory, motor, behavioural or contextual factors limited interpretation, and reports the assessor's conclusion in its proper scope. It then explains how that conclusion affects the immediate clinical

plan. The final step is essential. A report should change an action, a question, a referral or the level of certainty, rather than become an isolated attachment in the case file.

Avoid false precision. If the result is limited, say what limited it and what remains possible to conclude. If it supports a concern, distinguish this from establishing the whole condition or explaining every difficulty. If it is reassuring in the narrow domain sampled, state that narrowness. This language is not defensive hedging. It is professional accuracy, and it helps families understand that assessment is intended to open useful support rather than to impose a fixed identity on the child.

Feedback should be conducted in language that preserves dignity. Lead with what the child was able to do and how the assessment informs practical support. Explain uncertainty without making it sound like failure. Where family members request only a label, bring the conversation back to the child's current needs, opportunities for participation and the next question that needs answering. This stance reduces the risk that a test outcome becomes either stigmatising or falsely reassuring.

MNEMONIC

QUESTION

Question asked, testing **U**nderstanding, **E**ngagement, relevant **S**ensory or motor factors, observed **T**ask strategy, **I**nterpretive limits, **O**utcome for care, and **N**ext assessment step. Use this as a reporting spine, not as a substitute for clinical judgement.

12.9 Boundaries of the battery and cross-references

Intelligence measures and focused performance tasks are only one part of a child assessment. They do not substitute for developmental screening, an adaptive account, symptom ratings, play-based engagement, or a tailored neuropsychological evaluation when those are the actual clinical questions. Requests for a battery should therefore be revisited when the original question changes. Adding tests without a question can make a report longer without making it clearer.

For Binet-Kamat and **MISIC** as intellectual-disability grading tools, and for the wider clinical approach to intellectual disability and autism spectrum disorder, see *the Intellectual disability and autism spectrum disorder notes*. This section deliberately does not convert an IQ result into a severity grade. The grading decision depends on a broader clinical account and belongs with that discussion.

Similarly, normal development, developmental expectations and milestones are considered in *the Normal child development and milestones notes*. If the immediate question is a developmental screen or an adaptive-developmental tool, use the dedicated discussion of screening within this chapter rather than treating an intelligence instrument as a substitute. Clear boundaries between instruments make referrals more efficient and conclusions less misleading.

Choose the test by the question, interpret the child's performance in context, and never let a score do more clinical work than the assessment can support.

13 · Adaptive and developmental screening (VSMS, DST, DDST)

Screening is a decision aid, not a developmental verdict. In child psychiatry, a brief developmental or adaptive screen helps the clinician decide whether a reported concern deserves fuller assessment, what function is affected in everyday life, and which informant or service should be brought into the next step. Its marks lie in choosing the right tool for the question, administering it with discipline, and interpreting its result within the child's lived context.

The useful distinction is between a developmental screen, which samples observable attainments against an expected sequence, and an adaptive measure, which asks how the child manages ordinary demands in the environments in which the child actually lives. Neither replaces a careful history, examination, observation, or collateral account. The general assessment frame belongs with the principles of child psychiatric history and examination; this section concentrates on the narrow but clinically important work of using the VSMS, DST and DDST without turning a score into a diagnosis.

13.1 What screening contributes to assessment

Developmental screening is best understood as a structured way of making uncertainty visible. A parent may say that a child is "slow", "not listening", "unable to manage", or "different from the other children". These descriptions are clinically valuable but broad. A screen organizes the concern into functions that can be discussed, observed, and followed over time. It can also prevent the opposite error: dismissing a concern because the child appears comfortable or cooperative in a brief clinic encounter.

The screen is therefore an entry point to clinical reasoning. A finding that warrants concern should prompt the clinician to ask whether the observation is consistent across settings, whether the opportunity to learn the skill has been present, whether communication or sensory factors alter performance, and whether the caregiver's account describes capacity, opportunity, or a contribution from each. An apparently reassuring result should likewise be tested against the referral question. A child can perform a sampled task in a calm room yet struggle substantially with transitions, self-care, peer demands, or the pace of school.

CLINICAL TASK	WHAT THE TOOL CONTRIBUTES	WHAT REMAINS CLINICAL WORK
Clarify a vague concern	A shared functional language for the caregiver and clinician	History of onset, context, strengths and burden
Identify a possible delay	A structured prompt to consider further evaluation	Decide whether the concern is persistent, meaningful and corroborated
Describe everyday ability	Information on what the child does in ordinary settings	Distinguish ability from opportunity, support and expectation
Plan the next contact	A baseline language for reviewing change	Set goals with the child, family and relevant services

RULE **Use a screen to formulate the next question, never to close the case.** The result gains meaning only when it is integrated with developmental history, direct observation, caregiver account, school information where relevant, and the reason the child was brought for care.

This stance matters especially when a family arrives seeking a certificate, a label, or reassurance. The psychiatrist should neither promise certainty from a brief measure nor treat the family's concern as less real because a screen is not diagnostic. Instead, explain what the tool can contribute: it can map the concern, show which areas need closer attention, and provide a disciplined basis for deciding what assessment or support should follow.

13.2 Developmental attainment and adaptive functioning

Adaptive functioning concerns the practical translation of a child's capacities into daily participation. It is not identical to a test-room performance. A child may know how an activity is done yet not carry it out independently because the environment is confusing, routines are inconsistent, assistance is excessive, communication is limited, or anxiety disrupts performance. Conversely, a child can have a narrow skill repertoire but use familiar routines very effectively with stable support.

For this reason, adaptive enquiry works best when anchored to concrete examples. Ask the caregiver to describe what happens before, during and after a routine rather than accepting global labels such as "independent" or "dependent". Clarify who initiates the activity, how much prompting is needed, whether the child completes it safely, and whether the performance is habitual or exceptional. The aim is not to interrogate parenting. It is to establish the child's ordinary level of functioning in the family's actual circumstances.

Developmental screening samples attainments across functional areas, whereas adaptive assessment foregrounds real-world management. The distinction is clinically useful but should not be made artificially rigid. Each depends on the quality of the informant's report, the child's opportunity to practise, cultural expectations, language used in the interview, and the clinician's precision in recording an answer. A developmental concern can be recognized through everyday function; an adaptive difficulty may point back to a developmental, communication, emotional, physical, or environmental explanation.

GOOD TO REMEMBER

When caregiver and clinic observation do not agree, preserve each account rather than choosing a winner. The discrepancy is often the useful clinical datum: it may reveal a difference between structured and unstructured settings, between a familiar caregiver and an unfamiliar examiner, or between what the child can do and what the child routinely does.

13.3 Vineland Social Maturity Scale in Indian practice

The **Vineland Social Maturity Scale**, or VSMS, is particularly useful when the clinical question is about social maturity and everyday adaptive abilities. It was originally developed by **Doll** and adapted for India by **Malin**. That Indian adaptation makes the measure familiar in local clinical and teaching settings, but familiarity must not become ritual. Its value comes from a careful semi-

structured caregiver interview, not from treating its result as a self-explanatory property of the child.

The Indian adaptation covers **eight social domains and 89 items**, and is usable **from birth to 15 years**. This breadth supports an account of how the child manages across everyday activities rather than a narrow snapshot of one skill. The interviewer should know the manual and retain the wording and sequence needed for standardized administration. In teaching material and routine clinical discussion, it is safer to describe what the scale assesses than to reproduce protected content or substitute improvised items.

Its derived index is the **Social Quotient**, obtained by converting social age into that named index. The index can be useful as a compact summary and as a way to communicate a baseline, but the profile behind it matters more for intervention planning. A single composite cannot tell the team which routines are already established, which require cueing, which are limited by communication, or which depend on family accommodation. Those details should be carried forward into the formulation and practical plan.

IN INDIA

The VSMS has a recognisable place in Indian child assessment because of the Malin adaptation. Use it as an informed caregiver interview about the child's daily social maturity, while keeping the interview sensitive to the household's routines, available supports, language and expectations. A result is most useful when the narrative examples that produced it are retained in the clinical record.

TRAP **Do not convert an adaptive score directly into a diagnosis or a fixed prognosis.** The measure describes functioning through the information obtained at that assessment. It does not settle the causes of difficulty, replace a broader assessment, or tell the clinician which support will be effective without considering the child and environment.

13.4 DST: using a local developmental screen responsibly

The DST belongs with developmental screening rather than with formal intelligence testing. In an examination answer, its role should be stated modestly: it provides a structured sampling of developmental attainments and helps determine whether a fuller developmental evaluation is indicated. The clinician should use the authorised manual, local training and the version available in the service. Item content, scoring rules, thresholds, psychometric indices and normative claims should not be reconstructed from memory or inferred from another instrument.

A defensible DST encounter begins before the child is asked to do anything. Establish the referral question, the language used at home, the child's current health and comfort, the opportunity to practise relevant skills, and the person who can give the most reliable developmental account. During administration, create enough rapport for the child to engage, but do not coach the performance into a pass. If a caregiver supplies an answer, record it as caregiver report rather than converting it silently into observed performance.

- Record the reason for screening in functional language.

- Separate direct observation from caregiver report.
- Document conditions that may have altered engagement or performance.
- State the next assessment or referral question generated by the result.

The result is most helpful when it changes a decision. That decision may be to obtain collateral information, arrange a more comprehensive developmental assessment, explore a communication or sensory barrier, review the child after support has been instituted, or explain why no immediate escalation is needed despite a caregiver's understandable worry. It is not enough to write "screened" in the notes. The clinical record should show what was screened for, what was learned, what remains uncertain, and what will happen next.

PITFALL

Do not mix observation, reported ability and examiner assistance into one undifferentiated result. A child who succeeds only after repeated prompting has supplied different information from a child who completes the task spontaneously. The distinction changes formulation and the usefulness of later comparison.

13.5 DDST-II: scope and domains

The **Denver Developmental Screening Test, second edition**, or DDST-II, is a formal developmental screening tool for children **from birth to 6 years**. It samples development across **four domains**: **personal-social**, **fine motor-adaptive**, **language**, and **gross motor**. These headings help the psychiatrist describe where the concern lies without assuming that difficulty in one area explains all other areas.

Its administration should remain faithful to the authorised instrument. This concerns validity and professional boundaries. A screening tool is a standardized clinical aid, not a collection of memorable tasks to be copied into notes, teaching slides or a waiting-room checklist. The psychiatrist may explain the domains and the purpose to a family, while retaining the manual's protected procedures for trained use.

When considering a DDST-II result, look first for coherence. Does the screened pattern fit the developmental history? Does the family describe similar performance at home? Is a language-related difficulty being mistaken for a more global limitation? Is pain, fatigue, fear, unfamiliarity, or poor cooperation making the session a poor sample of the child's usual abilities? A screen can flag a question, but it cannot resolve these competing explanations on its own.

Screen	Profile	Context	Plan
SAMPLES FUNCTIONING	SHOWS THE PATTERN	EXPLAINS PERFORMANCE	SETS THE NEXT STEP

13.6 Interpretation, communication and follow-through

Interpretation is an ordered clinical task. Describe the observed or reported pattern without premature labels, test the pattern against context and collateral information, then decide whether it calls for fuller assessment, support, monitoring, or explanation. This sequence protects against

false reassurance and unnecessary alarm. It also keeps the result connected to the reason for consultation rather than allowing the scale to become the whole encounter.

Communicate the finding in language that respects the caregiver's observation and avoids fatalism. Explain that the screen estimates how the child is managing in selected areas at that point, and that the next step depends on the whole assessment. Families often hear any score-like output as a permanent ranking. The clinician's task is to redirect attention toward the child's current strengths, the functions needing support, and the practical information still required.

Where there is a clinically significant concern, the referral plan should identify the question for the next professional rather than simply dispatching the family. Where follow-up is chosen, record the same functional targets so that change can be discussed meaningfully. Educational observations, family routines and communication needs can be reviewed alongside the screen, but a screening result should not be used to dictate an educational placement or a formal diagnosis.

For intellectual disability, its IQ-grading instruments and ASD, see the Intellectual disability and autism spectrum disorder notes. For normal temperament, developmental norms and milestones, see the Normal child development and milestones notes. These cross-references are important because developmental screening is frequently used near those questions, but it does not replace the assessment standards set out there.

MNEMONIC

Question, Context, Profile, Plan

Question: why screen now? **Context**: what may shape the performance? **Profile**: what pattern is actually present? **Plan**: what is the justified next step? This sequence keeps the clinician from mistaking a completed form for a completed assessment.

A developmental or adaptive screen is useful only when its pattern is interpreted in context and used to decide the next clinical step.

14 · Broad-band rating scales (CBCL, SDQ, DBC)

Broad-band rating scales turn concern into a structured description. They ask someone who knows the child to rate a defined set of behaviours, emotions and strengths, so that the clinician can see the pattern rather than rely on an undifferentiated report that the child is "difficult" or "not coping". Their value lies in disciplined screening, in comparing settings, and in making subsequent change visible. They do not replace a history, direct observation, developmental examination, physical assessment, or clinical formulation.

A score is therefore an aid to judgment, not a diagnosis in miniature. A parent may be describing a child at home under stress; a teacher may be describing the same child in a highly structured setting; the young person may be reporting internal experience that neither adult sees. The useful clinical question is not simply whether the ratings agree. It is what each rating adds, what the

disagreement means, and whether the pattern alters the next assessment step. This instrument-specific use of an **informant** is central to multi-informant broad-band screening with the **Child Behavior Checklist (CBCL) / ASEBA**, the **Strengths and Difficulties Questionnaire**, and the **Developmental Behavior Checklist 2**.

2-17	25	5	5
SDQ AGE RANGE	SDQ ATTRIBUTES	SDQ DOMAINS	DBC2 SUBSCALE SCORES

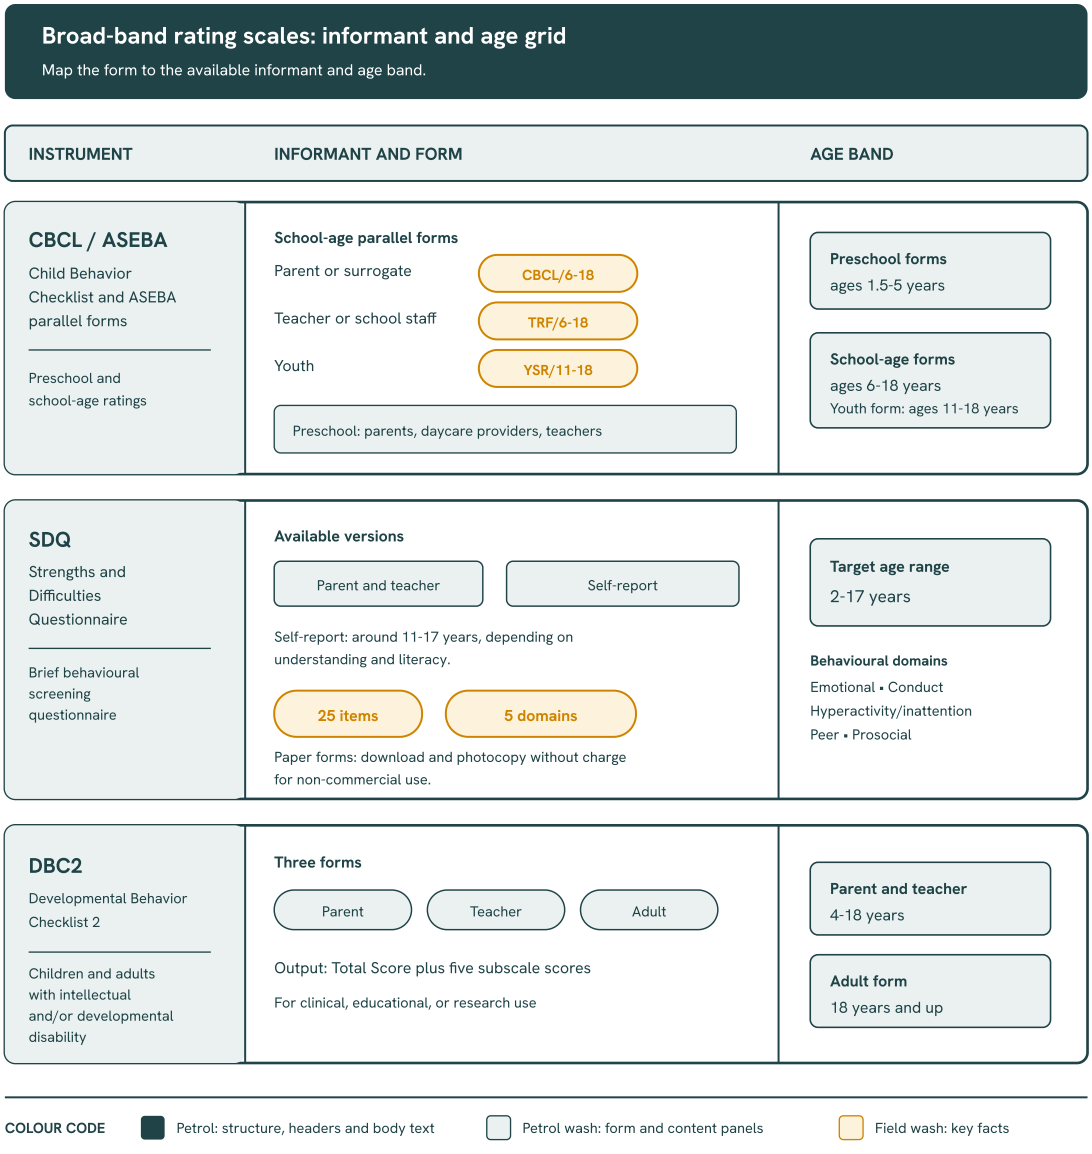

Fig 24.8. Broad-band rating-scale options differ in their available informants and age bands. The SDQ row additionally identifies its item count, behavioural domains, and non-commercial paper-use status.

14.1 What broad-band scales contribute

A **broad-band rating scale** samples difficulties from more than one clinical territory rather than beginning with a single suspected diagnosis. It is particularly useful when the referral question is broad, when the presenting complaint has changed across settings, or when the clinician needs a

common language for parents, school staff and the child. It can make hidden internalising distress easier to ask about, prevent a disruptive presentation from eclipsing strengths, and provide a baseline before an intervention is started.

The scale is not an interview performed on paper. It cannot establish onset, sequence, precipitants, meaning, developmental appropriateness, exposure to adversity, medical contribution, risk, or impairment in the manner required for clinical decision-making. A high score identifies a signal that merits explanation; a low score does not overrule a coherent history of distress or danger. The same item endorsement can have different significance depending on language ability, sensory profile, family expectations, classroom demands, and the situation in which the rater has observed the child.

RULE **Use a broad-band score to sharpen the clinical question, never to close it.** The response pattern should direct further history, observation and collateral enquiry. It should not be used as a substitute for deciding whether the reported behaviour is persistent, impairing, context-bound, developmentally expected, or better explained by another difficulty.

For this reason, broad-band screening is most defensible when the referral question is written before the form is chosen. “What is happening at home and school?” is a different question from “Has the child’s emotional burden changed since the last review?” A scale can serve either purpose, but the interpretation must match the purpose. It is poor practice to administer a familiar questionnaire merely because it is available and then let its score dictate the assessment agenda.

14.2 The informant is part of the measurement

In child work, the rater is not a neutral delivery system. Each informant samples a different relationship, setting and threshold for concern. Parents may be best placed to describe routines, transitions, sleep-related strain, sibling interactions and the child’s recovery after distress. Teachers may contribute sustained comparison with classroom expectations, peer participation, task persistence and response to structure. A young person may disclose worry, shame, loneliness or thoughts that are not outwardly visible. The record should identify who completed the form, what relationship they have to the child, and the period and context that guided their answers.

Informant discrepancy is clinical data, not a defect to be averaged away. Concordant concern across settings can support the impression of a pervasive problem, but disagreement should lead to hypotheses rather than a search for the “correct” rater. Home-only difficulty may point towards demands, routines, relationships or unstructured time that require exploration. School-only difficulty may reflect academic load, peer dynamics, sensory demands, discipline practices or a mismatch between the child and the environment. Self-report that is more severe than adult report deserves a careful, private discussion; it is not disproved by an outwardly composed presentation.

At the same time, discrepancy is not automatically meaningful. A rater may have had too little recent contact, may misunderstand an item, or may answer from a moment of acute conflict. Clarification is often more valuable than immediately repeating the questionnaire. Ask for

examples, antecedents, consequences and exceptions. Then decide whether a second informant, direct school contact, a focused interview, or another component of the assessment is needed. The broader framework for child psychiatric history and examination belongs with the assessment principles section of this chapter; the point here is that the form itself gives a structured way to organise collateral evidence.

GOOD TO REMEMBER

When scores diverge, place the forms side by side before the next interview. Ask about the items on which the accounts differ, not only the overall result. This often converts an apparent disagreement into a useful account of setting, demand and relationship.

14.3 CBCL and the ASEBA approach

The CBCL is used within the ASEBA family of parallel forms. Its practical strength is that comparable information can be sought from the adult caring for the child, school personnel and the young person, instead of treating one account as the whole case. At school age, the relevant forms are **CBCL/6-18, TRF/6-18 and YSR/11-18**. They are completed respectively by a parent or surrogate, a teacher or other school staff member, and the young person. This structure makes it possible to compare a home account, a school account and the child's own account without pretending that they are interchangeable.

The preschool family is also explicitly multi-informant: it covers **ages 1.5 to 5 years** and can draw on accounts from parents, daycare providers and teachers. That matters because early-childhood behaviour is highly dependent on routine, caregiving style, language development and the demands of the setting. A report of a behaviour in one environment should prompt inquiry into its context rather than a premature inference of stable psychopathology.

In clinical use, start with the reason for selecting the form. If the consultation concerns a mismatch between home and school, obtain the relevant adult accounts close enough in time that they represent the same clinical period. If the young person's experience is central, create conditions in which completing a self-report is private and comprehensible, then discuss it rather than leaving it unexplained in the file. The scale profile is best read as a map of areas needing clinical clarification. It does not decide what the child "has", and it should not be used to make a categorical diagnosis without the requisite assessment.

INSTRUMENT FAMILY	WHAT ITS STRUCTURE CONTRIBUTES	CLINICAL USE OF THE COMPARISON
CBCL / ASEBA	Parallel home, school and youth accounts where the relevant forms are used	Locates whether concerns are shared across settings or concentrated in one context
SDQ	A brief screen covering difficulties as well as a strength domain	Provides a concise initial overview and a language for focused follow-up
DBC2	Parallel adult perspectives and an overall score with subscale information	Frames behavioural and emotional concerns where developmental disability shapes presentation

TRAP **Do not turn cross-setting disagreement into a contest between parent and teacher.** Both may be reporting accurately from different environments. Treat the discrepancy as a question about context, exposure and demand, then test that question in the history.

14.4 SDQ as a concise broad-band screen

The SDQ is a brief behavioural screening questionnaire for children and adolescents. It asks about psychological attributes, including positive as well as negative attributes. This is clinically useful because a brief screen that records prosocial capacity alongside difficulties can prevent the assessment from being framed solely in deficit language. It is still a screen: a score pattern should lead to enquiry about severity, duration, impairment and context, rather than being read as a diagnosis.

The attributes are organised into behavioural domains covering emotional symptoms, conduct problems, hyperactivity/inattention, peer relationship problems and prosocial behaviour. The domains are a way of structuring attention, not a replacement for formulation. For example, a peer-related concern may require enquiry into anxiety, social communication, bullying, exclusion, language, classroom climate or a developmental difference. Similarly, a score suggesting difficulty with attention needs a full account of sleep, mood, learning demands, stress and context before it has diagnostic significance.

A **self-report version** is suitable for young people **around 11 to 17 years**, depending on understanding and literacy. The clinician should therefore check comprehension rather than assume that chronological age alone guarantees meaningful self-report. If the young person needs help with wording, preserve privacy and avoid coaching a preferred answer. The aim is to understand their perspective, not to manufacture agreement with the adult forms.

The SDQ can be especially practical when a brief, repeatable screen is needed and when a school or family can complete it without a lengthy assessment session. Its paper forms can be obtained and copied without charge for **non-commercial use**. That access should not be confused with permission to alter the instrument or to treat an informal translation as equivalent to an authorised form. Use the available version as intended, record which version was used, and retain the original response sheet or a faithful clinical record.

PITFALL

A brief score is often copied into a referral letter without the rater, setting or reason for administration. This makes the number clinically thin. Record the informant and context beside the result, and document the question the screen was intended to answer.

14.5 DBC2 when developmental disability is central to presentation

DBC2 is designed for behavioural and emotional assessment in children and adults with intellectual and/or developmental disability. It is useful when communication differences, adaptive dependence, physical health burden, sensory needs or environmental support may alter how distress and challenging behaviour are expressed. The clinical task is not to reduce a behaviour to the developmental condition. Rather, ask what the behaviour communicates, what has changed, which demands precede it, and whether pain, fear, loss, trauma, mood, communication frustration or a change in support could be contributing.

Its parent and teacher forms apply from **4 to 18 years**, while its adult form applies from **18 years and up**. The **Parent, Teacher and Adult forms** provide parallel perspectives, and the measure yields an overall score together with subscale scores. This allows behaviour to be described across familiar environments, but it does not determine cause. A change in score should trigger review of health, communication, routine, support and safeguarding, alongside psychiatric assessment where indicated.

In a child with developmental disability, the most useful preparation for a DBC2 discussion is concrete collateral: a description of the behaviour, the setting in which it happens, changes from the child's usual pattern, what reliably precedes it, and what follows. This protects against diagnostic overshadowing, in which distress is attributed to disability and a treatable contributor is missed. For intellectual disability and autism-spectrum assessment itself, consult the Intellectual disability and autism spectrum disorder notes; the present role of DBC2 is broad behavioural screening and structured follow-up.

14.6 From score to formulation and follow-up

Interpret a profile in layers. First, establish whether the form is complete, intelligible and relevant to the current clinical period. Next, identify the broad areas that require interview and observation. Then compare informants and settings, looking for convergence, divergence and missing perspectives. Finally, integrate the rating with functional impact, risks, strengths and the child's account. The report should distinguish clearly between what the instrument records and what the clinician concludes.

Measurement-based follow-up is valuable only when the same construct, informant and context are reasonably comparable over time. A changed score may reflect clinical change, but it can also reflect a new teacher, altered school demands, a family crisis, better understanding of the items, or a different person completing the form. Notes should therefore state the intervention or event occurring between ratings and any change in informant or setting. This prevents false confidence in apparent improvement or deterioration.

- State the referral question before administering the scale.
- Record the instrument version, informant, setting and date in the clinical note.
- Read the profile beside history, observation and impairment, not in isolation.
- Discuss discrepant findings with the relevant informant and, where appropriate, the child.
- Use a repeated measure only when it will answer a defined follow-up question.

IN INDIA

Collateral often has to be assembled across family members, teachers and changing school arrangements. Explain the purpose of the questionnaire in the respondent's preferred language, check that the questions are understood, and avoid treating limited literacy or unfamiliarity with questionnaire formats as evidence of psychopathology. A school form is useful only when the respondent has had enough opportunity to observe the child.

Feedback should be proportionate and non-stigmatising. Explain that the form describes reported difficulties and strengths in a particular context, and that the next step is to understand why they are present. Share only information needed for the agreed clinical purpose, especially when communicating with school. The child and family should not be left with a score whose meaning has not been explained, nor should a school be asked to act on a label that the assessment has not established.

14.7 Choosing and documenting the right scale

Selection starts with fit, not prestige. Choose a broad-band scale when the clinical question calls for a broad description of behaviour and emotion, when multiple settings need comparison, or when a structured baseline will guide later review. Choose the particular family according to the child's developmental context, available informants, respondent comprehension, and the practical setting in which the information will be used. A questionnaire chosen for convenience but mismatched to the child or respondent can create spurious precision.

Document interpretation in ordinary clinical language. A useful note identifies the source of each account, describes the pattern that emerged, names the main uncertainties, and sets out the follow-up questions. It should also record strengths and protective factors reported on the form or in interview. This is more clinically durable than copying a score alone, because another clinician can understand the reasoning and can decide whether a later change represents a real shift or a change in circumstances.

MNEMONIC

SCALE

Source, **C**ontext, **A**greement, **L**imits and **E**xplanation. Before acting on a broad-band result, identify who rated, where they know the child, what agrees or differs, what the form cannot establish, and what clinical explanation must now be tested.

A broad-band rating scale is most useful when its score is interpreted as one informant's structured account within a full clinical formulation.

15 · Projective tests in children (CAT, draw-a-person)

Why it matters clinically. Projective material is often memorable because it seems to offer a route into a child's inner world without demanding a direct verbal account. That apparent immediacy is also its danger. A child's story or drawing is an encounter between the child, the task, the examiner, the setting, and the meaning assigned afterwards. It can enrich an assessment when used as a prompt for curiosity, but it becomes unsafe when it is treated as a shortcut to a diagnosis, a hidden event, or a fixed personality conclusion.

For the psychiatrist, the examinable skill is not to recite supposed symbolic meanings. It is to know what the instrument asks the child to do, what kind of clinical material it can generate, and where its inferences must stop. Projective techniques belong after the general assessment framework, not in place of it. That framework is set out in *Principles of child psychiatric history and examination*.

CAT	DAP	Context	Adjunct
NARRATIVE PROMPT	HUMAN-FIGURE TASK	MAKES MEANING SAFER	NEVER THE WHOLE ASSESSMENT

15.1 What a projective method contributes

A projective method gives the child an ambiguous or relatively open task and attends to the response that follows. The response may be a story, a choice, an elaboration, a refusal, a drawing, a question to the examiner, or a change in affect while doing the task. Its value is therefore qualitative. It can make themes easier to approach when a child has difficulty discussing feelings directly, is unsure what is permissible to say, or is more comfortable communicating through play and imagery than through an interview.

The clinically useful output is a *hypothesis*, not a finding that proves itself. If a child repeatedly centres a theme, the examiner asks whether that theme is also visible in the history, behaviour, relationships, and the child's own later account. If it is not, it remains an observation needing exploration. This protects against the common habit of converting a striking image into a conclusion before the child has been heard.

RULE **Read projective material as a conversation starter, not as a verdict.** Its contribution is strongest when it helps the clinician ask a better next question and weakest when it is used to replace ordinary clinical evidence.

Interpretation must distinguish the product from the process. A bleak story may reflect current worry, imaginative preference, misunderstanding of the task, recent experience, fatigue, or the child's sense of what the adult expects. Likewise, a sparse drawing may be affected by comfort with drawing, visual-motor skill, motivation, time pressure, and the relationship with the

examiner. Recording the child's spontaneous comments and the examiner's invitations is often more clinically informative than preserving an isolated conclusion about the finished product.

- Describe what was actually said, drawn, chosen, or avoided before assigning possible meaning.
- Ask gentle, open follow-up questions that allow the child to confirm, revise, or reject the clinician's initial impression.
- Seek convergence with history, observation, and collateral accounts before a theme influences formulation or management.

15.2 Children's Apperception Test: a narrative task

The **Children's Apperception Test**, commonly abbreviated as CAT, is a projective technique built around pictures. It is associated with **Leopold Bellak, MD, and Sonia Bellak**. The task presents a set of **10 animal pictures** in social situations that include conflict and interpersonal relationships. The child's narrative, the way characters are understood, and the child's manner of engagement give the interviewer material to explore rather than material to decode mechanically.

The stated age range is **3 years to 10 years**. This is an aid to task selection, not a substitute for judgment about whether a particular child can understand and tolerate the task. Before beginning, the examiner should create a calm, non-evaluative atmosphere. The child should not be made to feel that there is a correct story or that the clinician possesses a concealed answer. A brief, natural invitation to tell what seems to be happening is usually more useful than repeated prompting that turns the task into a performance.

During administration, the psychiatrist should attend to the child's approach to the picture as well as the narrative itself. Does the child begin readily, seek reassurance, change the task, repeatedly ask what the examiner wants, become playful, or disengage? Does the narrative permit multiple feelings and outcomes, or does it close rapidly around danger, blame, rescue, exclusion, or triumph? Such features may indicate where a careful interview could go next. They do not establish why the feature occurred.

A practical record gives a near-verbatim account of the story and the child's behaviour. It also records tentative themes in ordinary clinical language, with alternatives rather than certainty, and notes questions to be tested elsewhere in the assessment. This prevents an attractive interpretation from hardening into the record as though the child had stated it directly.

> **GOOD TO REMEMBER**
>
> If a CAT story raises a concern about a relationship or experience, return to the child with an age-appropriate open question and examine the concern against the rest of the assessment. The useful move is clarification, not interpretation by authority.

IN INDIA

Language, family idiom, and the child's familiarity with picture-based tasks shape the narrative. Use the language in which the child can play with ideas most naturally, and document whether an interpreter, caregiver presence, or the clinic setting may have altered the exchange. A translated answer should never be stripped of its context and treated as a literal psychological code.

15.3 Reading CAT responses responsibly

A story should be approached as jointly produced material. The image makes some possibilities more available; the examiner's voice and pace influence what the child risks saying; and the child may be responding to the adult as much as to the picture. The immediate task is therefore descriptive: who is in the story, what happens, what feelings are named, how relationships are arranged, and whether the child comments on the task itself. The next task is collaborative: ask the child to explain uncertain elements rather than filling them in.

Patterns can be clinically useful when they recur across material and fit independently obtained information. For example, a recurrent difficulty in imagining comfort may prompt exploration of support-seeking and caregiving relationships. A repeated focus on control may prompt exploration of the child's recent transitions or family interactions. In each instance, the word *may* matters. The method opens a line of enquiry; it does not identify a cause, establish an event, or rank the severity of a problem.

Negative material should not be confused with pathology. Children use stories to rehearse fear, anger, competition, dependence, and repair. A dramatic narrative can be imaginative, situational, or developmentally understandable. The clinician's task is to consider intensity, persistence within the encounter, the child's own explanation, and convergence with the wider assessment. Equally, a cheerful story does not exclude distress. Children may protect adults, avoid frightening material, or choose a familiar social script.

TRAP **Do not convert a theme into a diagnosis or a factual allegation.** A projective response can justify further sensitive enquiry; it cannot carry a diagnostic or forensic conclusion on its own.

PITFALL

Do not reproduce proprietary pictures in notes, teaching slides, or informal messaging, and do not rely on a second-hand description of a stimulus as if it were the child's actual response. Record the clinically relevant narrative and process in your own words.

15.4 Draw-a-person tasks: method and history

A human-figure drawing task asks the child to make a drawing of a person and provides a different kind of material from a picture-based narrative. The finished drawing is visible, but the encounter also includes how the child begins, whether the child asks for help, the comments made while drawing, corrections, pauses, and the response to a follow-up invitation to talk about the figure. A drawing can be a gentle way to engage a child who is not ready for a sustained verbal

interview, provided the clinician does not mistake familiarity with drawing for a window of equal clarity into mental life.

The **Draw-A-Man Test** was published in **1926** with **standardized instructions for administering and scoring a human figure drawing**. This historical point matters because it corrects a frequent conflation: a drawing task may have a structured scoring purpose, while a clinician may separately use drawings in a projective or conversational way. These are related only by the medium. They are not automatically the same clinical claim.

The earlier work was later restandardized and published as the **Goodenough-Harris Drawing Test** in **1963**. In its scored form, its primary purpose is a measure of **intellectual maturity**. The **projective aspects** of drawings are a distinct use and should not be silently imported into an intellectual-maturity score. For the broader developmental and intellectual assessment battery, see *Developmental and IQ tests*.

CLINICAL QUESTION	CAT RESPONSE	DRAW-A-PERSON RESPONSE	SAFE CLINICAL USE
How does the child make sense of an interpersonal scene?	A story built around pictured social material	Comments about the figure may emerge during or after drawing	Use the material to guide open questions
What happens during engagement with an open task?	Notice narration, pauses, questions, and affect	Notice approach, revisions, requests, and affect	Record the process as well as the product
Can the result stand alone as a clinical conclusion?	No	No	Seek corroboration within the assessment
What should be avoided?	Fixed decoding of a story detail	Fixed decoding of a drawing feature	State uncertainty and test alternatives

15.5 Clinical interpretation of a drawing

The central discipline is to avoid a dictionary approach. An isolated feature of a human figure does not carry a stable meaning independently of the child, the task conditions, and the wider assessment. A clinician who says that a particular feature proves a specific feeling has moved from observation to certainty without showing the necessary reasoning. The more defensible note describes the feature, records the child's account of it, and states how it did or did not fit the rest of the clinical picture.

Ask questions that preserve ownership of meaning with the child: "Tell me about this person"; "What is happening here?"; "What is this person thinking or feeling?"; "Is there anything you would like to add?" The exact wording should be adapted to the child's language and comfort. These questions often reveal whether the drawing was simply a task, a playful character, a self-referential account, or a story about someone else. They also make the assessment less intrusive than an adult narration imposed upon the child.

When drawing behaviour suggests difficulty, consider ordinary alternatives before assigning psychological significance. The child may have limited confidence with drawing, may be

preoccupied by the clinic, may be tired, or may be avoiding an unfamiliar adult. When the drawing seems highly elaborated, consider interest, practice, and the wish to please as well as emotional themes. This is not timidity. It is the ordinary clinical requirement to separate an observation from its possible explanations.

MNEMONIC

Describe, Ask, Corroborate, Explain uncertainty

Use this sequence for any projective response. **Describe** the response and process; **Ask** the child what it means; **Corroborate** against the wider assessment; and **Explain uncertainty** in the formulation rather than overclaiming.

15.6 Documentation, communication, and scope

The clinical note should make clear which parts are observation, which parts are the child's explanation, and which parts are the clinician's tentative formulation. It should also record the context of administration: privacy, interruptions, language used, the child's willingness, and any relevant influence of adults present. This is especially important when later readers did not witness the task. A concise, transparent note is more useful than a long interpretative paragraph that obscures what actually occurred.

In feedback to caregivers, describe the task modestly. It may be appropriate to say that the activity helped the child communicate themes worth exploring, then discuss those themes alongside the child's observed functioning and the family's account. It is not appropriate to present the drawing or story as an objective detector of a private fact. Such framing can alarm families, damage trust with the child, and distract from more reliable avenues of assessment and care.

Where there is a safety concern, the response is not to intensify symbolic interpretation. Clarify the concern using an appropriate child-centred assessment, preserve the child's words carefully, and follow the relevant safeguarding pathway. The safeguarding-specific evaluation is addressed in *Child sexual abuse assessment and psychiatric sequelae*, and the clinical response in *Management and intervention in child abuse cases*. Projective material should never be used to bypass either process.

Projective tests can deepen a child assessment only when their observations are kept tentative, explored with the child, and corroborated elsewhere.

16 · Multiaxial and multi-informant assessment in child psychiatry

Why it matters clinically. A child psychiatric formulation becomes thin when it is reduced to a diagnostic label. The clinician may have recognised a symptom pattern correctly yet still fail to record the developmental picture, physical health, psychosocial context, or the effect of difficulties on everyday life. The **WHO ICD-10 multiaxial classification** is useful as a

disciplined way of holding these domains together. It asks the clinician to write a structured account rather than allow the most conspicuous complaint to stand in for the whole child.

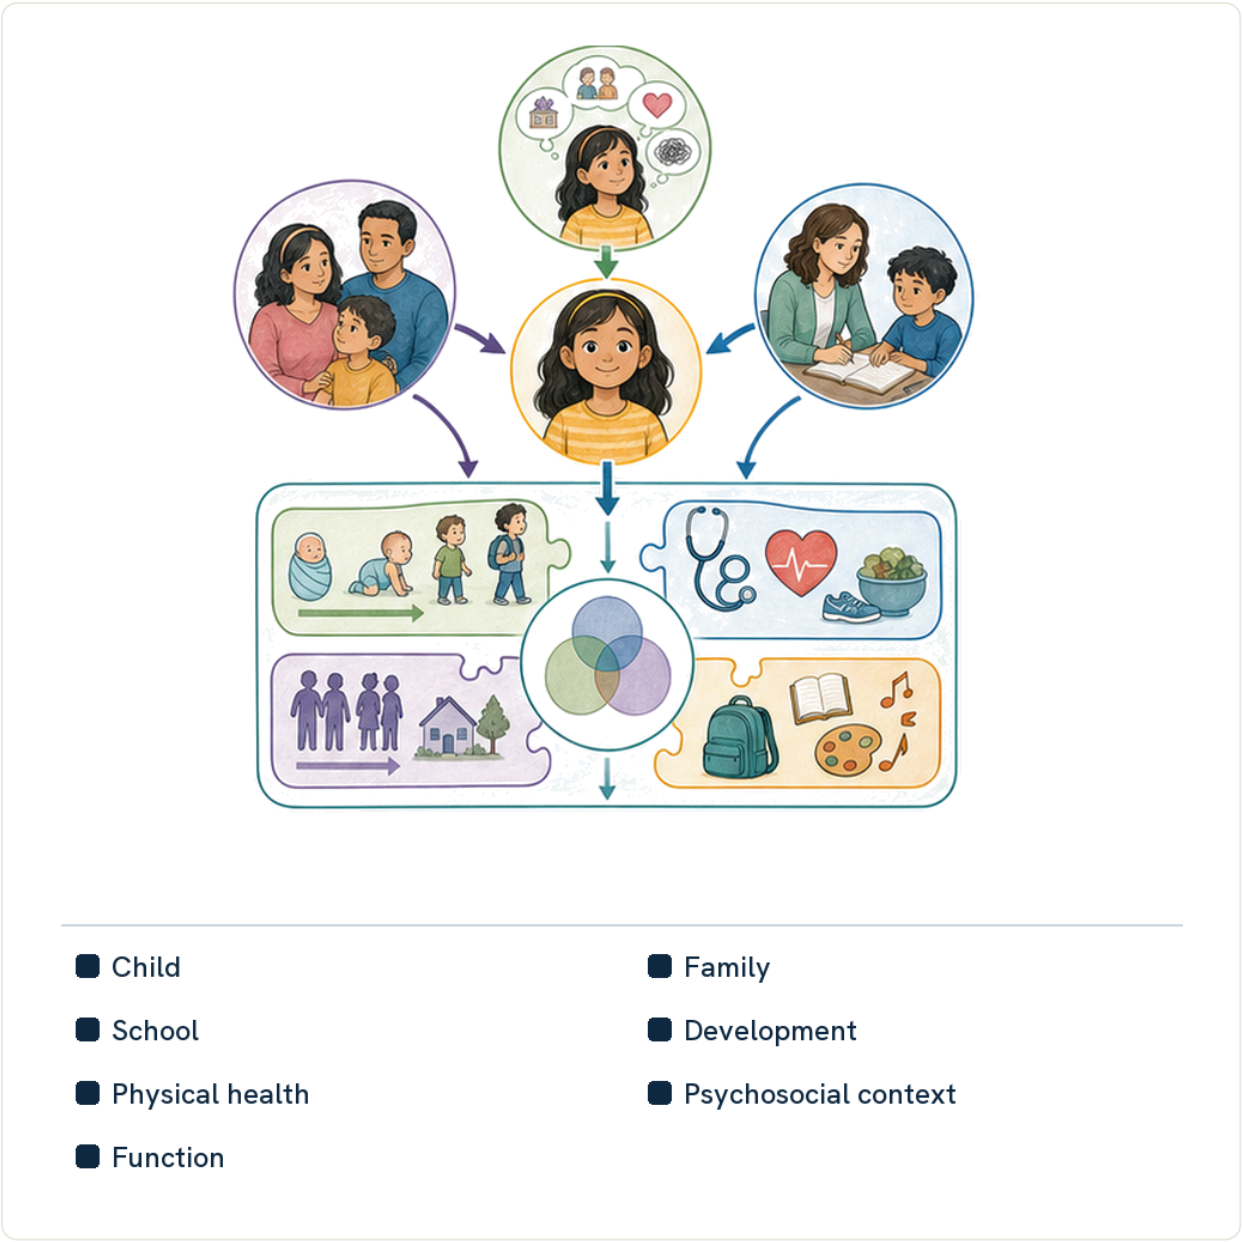

Fig 24.9 Child psychiatric assessment integrates the child's account with family and school information, then holds syndrome, development, physical health, psychosocial context and functional disability in one structured formulation.

The purpose is not to multiply diagnoses or to turn assessment into a coding exercise. It is to make clinical reasoning visible. A multiaxial record separates questions that are often blurred in hurried notes: what syndrome is present, what developmental factors matter, what physical conditions may alter presentation or treatment, what circumstances burden the child, and how much disability is being experienced. This separation makes omissions easier to see and makes the formulation more useful to families, schools, and colleagues.

WHO	BODY	CONTEXT	FUNCTION
STRUCTURED FRAME	MEDICAL CONTEXT	PSYCHOSOCIAL FIELD	DISABILITY RECORDED

16.1 What multiaxial assessment adds

Multiaxial assessment is a formulation scaffold. It does not replace a careful history, examination, developmental understanding, or collateral account. Instead, it gives each of these strands a defined place in the final record. That matters because the same outward difficulty can be shaped by developmental capacity, a medical condition, adversity, or functional impairment. A single-label summary can conceal these distinctions; a multiaxial summary obliges the clinician to state them.

The framework contains **six** axes. Read them as parallel descriptive fields, not as a ladder of importance. Clinical psychiatric syndromes and specific disorders of psychological development occupy different fields; intellectual level is recorded separately; physical conditions, psychosocial situations, and psychosocial disability are also given their own places. The practical gain is a record that can carry comorbidity and context without implying that one automatically explains the other.

RULE **Use axes to separate dimensions of a formulation, not to manufacture extra diagnoses.** A field is completed because it changes understanding, communication, or planning, not because a blank must be filled with speculation.

In a clinical note, this distinction protects against premature closure. A syndrome field may describe the current psychiatric presentation, while another field records developmental information that affects how symptoms are understood and how communication is adapted. A separate medical field prevents the physical examination and relevant health conditions from being treated as an afterthought. Context and disability fields then stop social circumstances and real-world impact from being appended as vague background prose.

16.2 Reading the axes as a biopsychosocial record

RECORD FIELD	QUESTION IT KEEPS OPEN	USE IN FORMULATION
Clinical psychiatric syndromes	What is the current psychiatric presentation?	States the clinical problem without claiming it is the whole explanation.
Specific disorders of psychological development	What developmental profile alters interpretation or communication?	Prevents developmental needs from being lost inside symptom language.
Intellectual level	What level of cognitive functioning is relevant to assessment and support?	Prompts accessible interviewing and realistic expectations.
Medical conditions	What physical health information belongs in the psychiatric formulation?	Keeps relevant bodily illness and its clinical implications visible.
Associated abnormal psychosocial situations	Which circumstances are linked to the child's difficulties?	Turns a generic social history into a clinically usable context.
Global assessment of psychosocial disability	How are difficulties affecting participation and everyday roles?	Brings functional consequence into the centre of the record.

The table is not a sequence to be completed mechanically. It is a set of safeguards against category error. A psychosocial situation may be relevant without being presented as the sole cause of a psychiatric syndrome. A medical condition may need active attention without becoming an explanation for every behavioural change. Similarly, a developmental difference may shape the interview and treatment plan without making distress less real. The axes help the clinician preserve these distinctions in language that another professional can follow.

The medical field is especially valuable when a referral arrives with an apparently psychiatric question but the child's health history has been summarised poorly. Its task is to record relevant physical conditions in the same formulation rather than leave them in a separate clinic note. This is not an invitation to diagnose beyond one's evidence. It is a prompt to decide whether medical information changes the differential understanding, risk appraisal, communication, or co-ordination of care.

> **GOOD TO REMEMBER**
>
> A useful axis entry is brief but consequential. Record the information that changes how the team understands the child or what the team must do next. Copying an undifferentiated social history into a context field creates length without formulation.

16.3 Context is neither cause nor excuse

Psychosocial circumstances deserve their own field because they are often clinically decisive, yet they should not be used as a shortcut to causal certainty. Context can maintain distress, limit attendance, alter what a caregiver can implement, or change the meaning of behaviour in a particular setting. It may also reveal strengths, available supports, and routes to practical help. A

formulation is stronger when it states the relationship it can justify and leaves causation open when the evidence does not justify more.

This approach also prevents moralising. Describing a difficult home, educational, peer, or care environment should not become a judgement about the child or family. The psychiatrist's task is to identify the clinical relevance of circumstances and translate it into a plan that can be shared. Neutral, observable language is more useful than labels that assign blame. It helps the receiving team see both burden and possibility.

IN INDIA

In Indian clinical records, the multiaxial frame can make fragmented information usable across home, school, health, and social settings. Write the context clearly enough that a colleague receiving the note understands what requires co-ordination, while avoiding assumptions about family motives, resources, or capacity.

TRAP **Do not write adversity as though it automatically proves causation.** The context field records clinically relevant circumstances. It does not license a causal story that has not been established, nor does it remove the need to describe the psychiatric presentation independently.

There is a second, quieter trap. When psychosocial information is scattered across the narrative, it can be mistaken for colour rather than clinical data. A distinct field asks the clinician to decide what is associated with the presentation and why it matters. That decision supports communication with other services without turning the psychiatric note into a catalogue of family details. Relevance, proportionality, and respectful wording matter as much as completeness.

16.4 Disability as a clinical outcome

The historical addition of **Axis Six** after the classification's introduction in **1993** made an important corrective: symptom description is not a sufficient description of a child's clinical situation. The axis directs attention to psychosocial disability, so that the formulation addresses what difficulties are doing to participation and everyday functioning rather than merely naming symptoms.

Its logic remains clinically useful even when contemporary documentation uses different formats. A child may appear less unwell in a brief consultation than in the environments where demands, relationships, transitions, and communication needs become visible. Conversely, conspicuous symptoms do not by themselves tell the clinician what the child can or cannot do with support. Recording **social disability** therefore anchors the formulation in consequence. It asks what has changed in the child's capacity to take part in ordinary life, and what support is needed to restore or protect that participation.

Disability should not be treated as a moral score or as a proxy for diagnostic severity. It is a separate clinical dimension. The interviewer should translate observations into functional language, identify setting-specific barriers, and distinguish a skill from the opportunity to use

that skill. This makes a formulation more useful for planning because it connects the clinician's account to supports that can be arranged and reviewed.

The stated purpose of this axis was a first move towards a systematic approach to assessing disability in young people with psychiatric disorder. That historical intention is worth retaining: function is not an optional closing sentence after diagnosis. It is part of what the clinician is trying to understand.

16.5 Multi-informant material: integrate, do not average

A child's assessment requires information from multiple perspectives, but the general multi-informant assessment framework, including how to obtain and weigh history, belongs with the child psychiatric history and examination. See the assessment framework in the chapter section on principles of child psychiatric history and examination. This fragment does not set out methods for collecting, prioritising, or reconciling informant accounts.

The boundary is important. *Multi-informant* describes the sources from which the clinical picture is built; *multiaxial* describes the dimensions in which that picture is recorded. They are complementary but not identical. In the final record, an informant account should support a clinical formulation field, not be mistaken for an axis in its own right. Where material remains uncertain, the formulation should say so rather than create agreement that the assessment has not established.

> **PITFALL**
>
> Do not turn a disagreement between accounts into an axial conclusion. An axis records the clinician's formulation of a domain; it is not a place to conceal uncertainty by presenting a disputed account as settled fact.

16.6 Turning the framework into a usable formulation

A concise final formulation can move from the current psychiatric presentation to developmental and cognitive context, then note relevant physical conditions, psychosocial situations, and functional disability. Each clause should earn its place by changing interpretation, communication, risk management, or the plan. This order is not a rigid script. Its value is that it forces the writer to show the relationship between dimensions while preserving the difference between them.

- Keep the current presentation distinct from developmental context.
- Record relevant physical conditions rather than burying them in general history.
- Describe psychosocial circumstances without converting them into causal certainty.
- State functional disability separately from symptoms.

MNEMONIC

FRAME

Formulate the presenting syndrome, **R**ecord developmental and cognitive context, **A**dd the relevant physical conditions, **M**ap psychosocial circumstances without asserting cause, and **E**stablish functional disability separately. Use it as a prompt for a coherent formulation, not as a substitute for clinical judgement.

When the record is shared, avoid unexplained technical shorthand. A formulation should be legible to the team and should make clear which statements are observed, reported, inferred, or still uncertain. It should also remain revisable. As further information becomes available, an axis can be clarified without rewriting the entire clinical story or pretending that earlier uncertainty was certainty. This feature makes the framework useful in longitudinal care.

Multiaxial formulation preserves the distinction between symptoms, context, physical health, development, and disability so that clinical planning addresses the whole child.

17 · Neuropsychological assessment of children (NIMHANS battery, executive function tests)

Why it matters clinically. Child neuropsychological assessment asks a different question from symptom counting: how is this child taking in information, holding it in mind, directing behaviour, learning from feedback and using skills in everyday demands? Its value is not a label produced by a test. Its value is a defensible account of a pattern of strengths and vulnerabilities that can explain why a child struggles in a particular context, despite apparently adequate ability or effort in another.

A useful assessment is hypothesis-driven. The referral question may arise from uneven school performance, apparently inconsistent attention, difficulty shifting away from a preferred response, slowed written work, or a mismatch between what the child can explain verbally and what the child can demonstrate independently. The clinician first decides whether a cognitive profile can add something to the clinical formulation, then specifies what observations or measures would materially change management. This keeps testing from becoming a collection of scores without a clinical argument.

Profile	Question	Evidence	Output
COGNITIVE PATTERN	FUNCTIONAL HYPOTHESIS	OBSERVED PERFORMANCE	PRACTICAL SUPPORTS

17.1 What neuropsychological assessment contributes

Executive functions are the control processes that help a child organise behaviour towards a goal. In the clinic, the question is rarely whether a child possesses an executive function in the abstract. It is whether the child can recruit control reliably when demands rise, distractions compete, rules change, feedback is disappointing, or an immediate response must be withheld.

The distinction matters because a child may perform well in a quiet, highly structured interaction and still fail when the same skill must be self-directed in daily life.

Neuropsychological work therefore converts a broad concern into more precise alternatives. A child who does not complete work may be struggling to sustain effort, to keep instructions active, to plan an approach, to shift after an error, or to regulate speed. Similar outward behaviour can arise through different routes. A profile does not remove the need for clinical judgement; it makes the judgement more explicit and tests whether the proposed explanation fits the child's performance across tasks.

RULE **Interpret a cognitive score as evidence about a process, never as a diagnosis by itself.** A score becomes clinically meaningful only when it is considered alongside the referral question, observed approach to tasks, developmental context and real-world functioning.

This is particularly useful when reports from home and school appear contradictory. A difference between settings may reflect different task demands, different levels of cueing, emotional load, fatigue, language demands or opportunities for distraction. It should not be converted automatically into an assertion that a child is choosing when to perform. The assessment helps identify what support allows a skill to appear and what conditions make it collapse.

17.2 The NIMHANS battery in Indian practice

The **NIMHANS Neuropsychological Battery for Children** is a structured option for child neuropsychological assessment. Its original citation credits **Kar, Rao, Chandramouli and Thennarasu**, with the **NIMHANS Publication Division** named as publisher in **2004**. What makes an age-referenced instrument useful is not merely that it produces a result. It allows the child's performance to be considered against **norms for each test at each age level**, rather than against an adult expectation or an informal impression of what children should manage.

IN INDIA

The reported growth-pattern work included **400 Indian school children between 5 and 15 years of age**. This makes the battery especially important as an Indian reference point. It does not, however, permit a clinician to treat every child from every linguistic, educational or social context as interchangeable with the reference group. Local relevance strengthens interpretation; it does not abolish the need to ask whether the comparison is fair for this child.

Norm-referenced assessment is a safeguard against an easy error: reading a performance as poor merely because it looks immature to the examiner. The reverse error is also possible. A child may appear socially fluent, compliant and bright in conversation but show a meaningful difficulty when a task requires self-monitoring or a novel rule. The examiner should describe the conditions of success and failure, not simply attach a global adjective such as “normal” or “impaired”.

17.3 Reading a profile across cognitive sections

The battery is organised into **five** section headings. These cover **motor speed**, **attention**, executive functions, **visuospatial functions**, and **comprehension, learning, and memory**. The

purpose of this organisation is clinical coherence. It encourages the examiner to look for convergence across related performances rather than to overvalue an isolated low result.

OBSERVED PATTERN	CLINICAL QUESTION	INTERPRETIVE DISCIPLINE
Slow or effortful output	Is the difficulty primarily in pace, control of response, understanding of the task, or persistence?	Describe the child's method and errors before drawing a conclusion.
Variable performance across tasks	Which demand changed: novelty, rule maintenance, interference, speed or cueing?	Seek a process explanation, not a character explanation.
Weak learning on a task	Was information encoded, retained, retrieved or used strategically?	Relate the pattern to the demands that trigger the referral.
Difficulty after a rule change	Can the child notice feedback and alter the response plan?	Do not confuse a single error with a stable inability.

For executive function, the informative observation often lies in the route to the answer. Does the child start before hearing the full instruction? Persist with a rule after it has changed? Need repeated external structure? Recognise an error but fail to repair it? Give up when the first strategy fails? Such observations are not decorative additions to a score sheet. They are the bridge from task performance to a clinical formulation of self-regulation.

- Record the child's understanding of the task and the kind of cueing required.
- Note whether errors are impulsive, perseverative, disorganised, slow or inconsistent.
- Ask what changed when the task became longer, less familiar or less structured.
- Connect the pattern only to the functional difficulty that prompted referral.

TRAP **Do not call every low executive-function result an attention disorder.** Executive control is influenced by comprehension, pace, motivation, emotional state, sensory or motor demands and the testing relationship. The task result narrows hypotheses; it does not settle them.

17.4 Administration as clinical observation

Standardised procedures matter because the meaning of comparison depends on administering a task as intended. Yet standardisation should not make the examiner passive. Behaviour during testing can qualify the result: delayed engagement, repeated checking, avoidance of uncertainty, overrapid responding, perfectionistic slowing, loss of the rule, or a response to praise and correction may each help explain a pattern. Record these observations clearly enough that another clinician can see how the conclusion was reached.

The testing relationship requires care. Children may interpret an unfamiliar task as an examination they can fail, or may protect themselves by refusing, joking, rushing or insisting that the activity is boring. The clinician should present the work in developmentally understandable language, preserve dignity when a task is difficult, and avoid turning a struggle into a contest.

This is not merely kindness. A threatened or disengaged child may be showing the examiner the consequences of the assessment context rather than the cognitive process that prompted referral.

GOOD TO REMEMBER

A useful report separates what was measured from what was observed and from what is inferred. "Performance was slow," "the child required repeated restatement of the rule," and "this may contribute to difficulty with multi-step work" are different kinds of statement. Keeping them separate makes the report more honest and more useful to the treating team.

17.5 From test pattern to treatment planning

The report should answer the referral question in practical language. A cognitive profile may guide the choice of environmental supports, the form in which instructions are given, the level of task structure, the need to reduce competing demands, or the way feedback is delivered. It can also clarify what should be monitored after an intervention begins. The report is strongest when its recommendations follow from the observed mechanism, rather than from a generic list of school accommodations.

Recommendations should be framed as testable supports. If difficulty appears when a child must hold several steps in mind, a support might make the sequence visible and check each step before the next begins. If performance deteriorates when a familiar rule changes, the support might make transitions explicit and allow guided practice with the new rule. The clinical team can then ask whether the proposed change improves participation and functioning. That feedback is more valuable than merely repeating a test score in later notes.

Assessment must remain integrated with the broader child psychiatric history and examination. A neuropsychological profile neither replaces the account of symptoms and relationships nor determines treatment in isolation. It provides a structured account of how the child approached cognitive demands, which can sharpen communication between psychiatrist, psychologist, family and school.

PITFALL

A polished numerical report can create false certainty when it is detached from the referral question. Avoid reproducing proprietary items, importing cut-offs from another setting, or presenting a score as if it explains behaviour without corroboration. The clinical task is interpretation, not score display.

17.6 Limits and communication of findings

Neuropsychological assessment samples performance under particular conditions. It cannot directly observe every demand in a classroom, home or peer setting, and it cannot decide whether a difficulty is fixed, situational or remediable without clinical follow-up. A finding may be limited by language fit, educational opportunity, fatigue, physical discomfort, anxiety, engagement or a child's understanding of why the assessment is occurring. These are not reasons to abandon assessment. They are reasons to state limits openly.

When explaining findings to caregivers, avoid converting cognitive language into a verdict on intelligence, character or future potential. Describe a pattern, the situations in which it matters, the strengths on which intervention can build, and the supports that will be tried. Families should leave with a clearer working model of the child's needs, not with a new stigmatising identity. The same discipline protects schools from treating a report as a reason to lower expectations indiscriminately.

- State the clinical question that made assessment necessary.
- Describe relevant observations during the work, including factors that limit confidence.
- Present the pattern before offering an inference about its functional significance.
- Make recommendations concrete enough to be tried and reviewed.

Neuropsychological assessment is most useful when it explains a functional difficulty through a coherent cognitive profile and turns that explanation into supports that can be tested in the child's real environment.

Therapeutic interventions

18 · Play therapy (principles, techniques, indications)

Play therapy is purposeful clinical work, not supervised recreation. It gives the child a mode of participation that does not depend on an adult-style verbal account. The clinician uses play to build a therapeutic relationship, understand the child's experience as it is communicated in action and imagination, and make psychological work possible without forcing premature explanation. The point is neither to entertain the child nor to extract a hidden meaning from every toy. It is to create a reliable interpersonal setting in which experience can be expressed, held, and worked with.

In the definition adopted by the Association for Play Therapy, **play therapy** is a systematic use of a **theoretical model** within an interpersonal process. Its distinctive resource is the **therapeutic powers of play**: play is used deliberately to help with psychosocial difficulties and to support development. This gives the method its clinical discipline. Materials, language, boundaries, interpretation and the therapist's participation all derive their meaning from the formulation and therapeutic approach, not from the presence of a toy box alone.

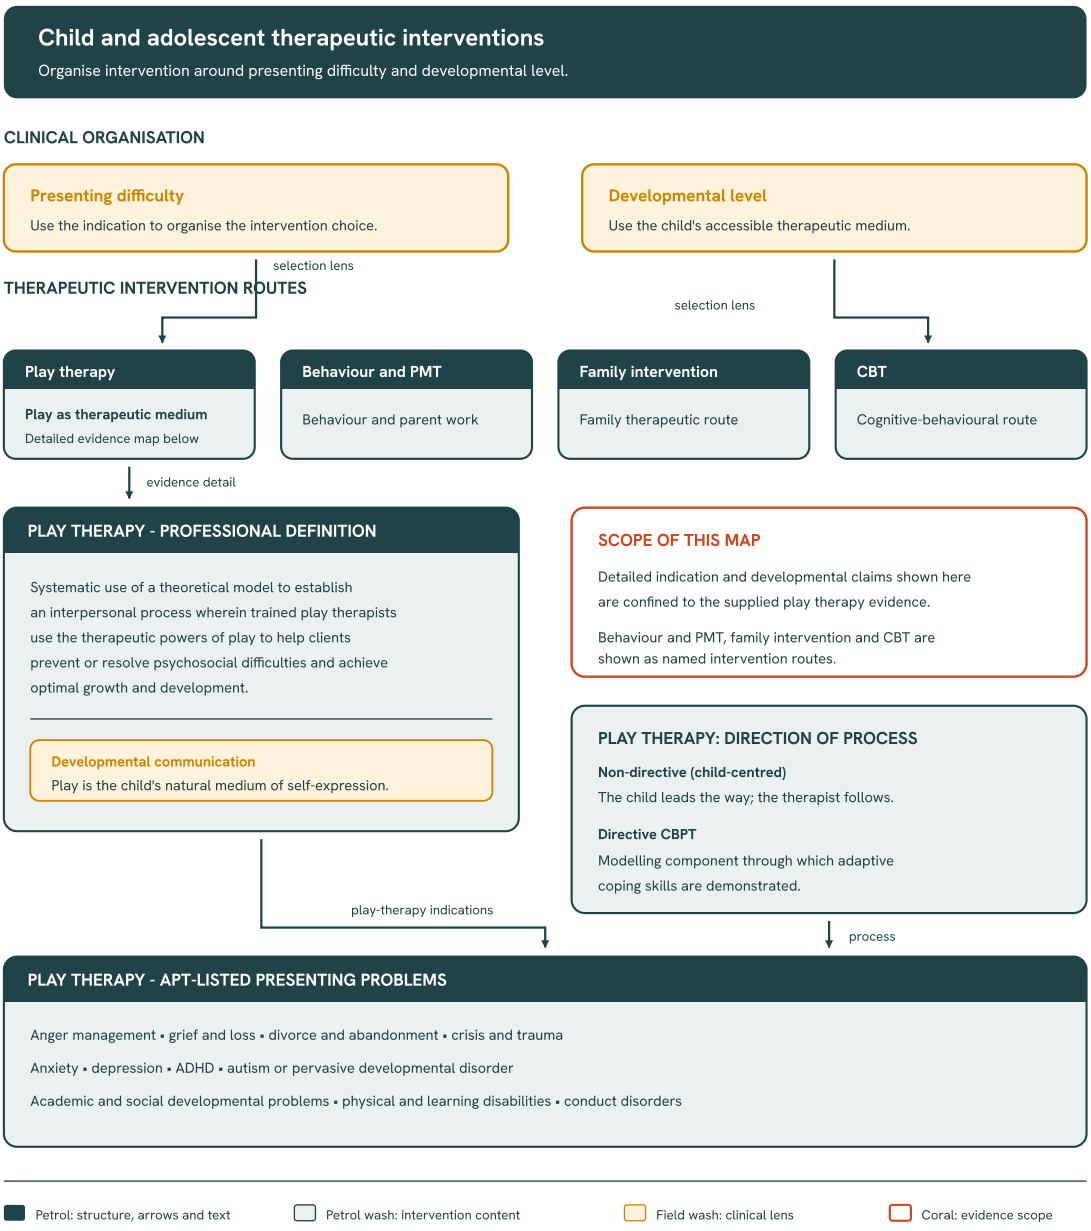

Fig 24.10. Therapeutic-intervention map for child and adolescent practice, organised around presenting difficulty and developmental level. The detailed route shows play therapy as a communicative medium, its directive and non-directive processes, and APT-listed presenting problems; behaviour and PMT, family intervention, and CBT remain named intervention routes.

18.1 Why play can become a therapeutic medium

In child work, experience can be known before it can be narrated. Worry may appear in a rescue scene, anger in a struggle over rules, or loss through disappearance and reunion. These are not codes to translate mechanically. Play creates enough distance for painful material to be approached while its emotional meaning remains alive in the room.

Axline's foundational proposition is that play is the **child's natural medium of self-expression**. The word "natural" should not be romanticised. It does not mean that every child will play freely, that every play theme is psychologically revealing, or that speech has no place in treatment. It

means that imaginative action, choice of role, repetition, construction, destruction, story and rule-making can give a child access to communication that may be less available in a direct adult interview. The therapist attends to the child's use of the medium, not merely to the objects selected.

Play also changes the balance of power in the clinical encounter. The adult remains responsible for safety, frame and professional purpose, but the child can initiate an action, alter a story, refuse a role, test a boundary or invite the therapist into a scene. This makes agency visible. Therapeutic work can then address not only the content of distress but also the child's manner of seeking closeness, managing frustration, using control, tolerating uncertainty and accepting help. What matters is the interaction that develops, not a performance judged as good or bad play.

RULE **Use play as a therapeutic language, never as a decorative substitute for therapy.** A play activity becomes treatment only when it is held in a purposeful relationship, guided by a coherent approach, and connected to the child's therapeutic needs.

18.2 The therapeutic frame

A therapeutic frame protects both spontaneity and safety. The child needs to know that the room is a place where choices can be made, feelings can be shown and difficult themes can be approached without ridicule. Equally, the child needs to discover that the therapist will not become chaotic, intrusive, frightened, punitive or collusive. The frame is therefore communicated as much through the therapist's steadiness as through spoken explanation.

Materials should permit expressive and relational uses rather than demand a correct outcome. They are offered as possibilities, not tests. The clinical question is not whether the child uses them as expected, but how choice, avoidance, repetition, pleasure, aggression, repair and participation appear in the shared space. The child must not be made to feel assessed for creativity, neatness or disclosure.

Boundaries are part of treatment rather than an interruption of it. A clear limit can show that powerful feeling is permissible while harmful action is not. The therapist names the limit calmly, offers a permitted alternative where possible, and remains available to the child's reaction. This can be therapeutically important for a child who expects either unrestricted escalation or punitive rejection. The limit must be real, however. A therapist who permits unsafe conduct in order to preserve rapport teaches that the clinical relationship cannot contain affect.

- Keep the purpose of the meeting clear without demanding a problem narrative at the outset.
- Offer choice, while retaining responsibility for the physical and emotional safety of the setting.
- Respond to feeling and relationship, not only to the visible product of play.

IN INDIA

An Indian play setting should not assume that a particular household, language, family role or cultural story is universal. Invite materials and examples that allow the child's own social world to enter the work. Ask caregivers about the child's ordinary play and preferred language, but avoid turning the family into interpreters of every symbol. Culturally responsive practice means staying curious about meaning while preserving the child's own voice.

18.3 Non-directive or child-centred practice

Child-centred play therapy places special weight on the child's initiative. The therapist aims to be accepting, emotionally available and closely attentive, while resisting the impulse to improve the story, educate the child, solve the conflict or make play conform to adult expectations. This stance is demanding because it requires the therapist to be active in attention and containment while not taking possession of the child's experience.

Axline's **sixth** principle, within her **eight** foundational principles, captures the working position: the child leads and the therapist follows. Following is not passivity. The therapist tracks what is happening, reflects feeling and action in language the child can use, notices shifts in relationship, and maintains boundaries. What the therapist does not do is turn every moment into a question, lesson, interpretation or correction. The child is allowed to discover that an adult can be present without taking over.

Reflection is often more useful than explanation in this approach. A brief response can acknowledge experience, make a sequence more thinkable, and leave ownership with the child. The therapist may reflect determination, disappointment, fear, pleasure or uncertainty without asserting why it exists. Interpretation is used with restraint because premature certainty can replace the child's unfolding meaning with the therapist's story.

Non-directive work should not be confused with lack of clinical responsibility. The therapist still decides whether this approach fits the child's needs, attends to risk and impairment, coordinates with the wider treatment plan, and recognises when the child requires a more structured intervention. It is a way of organising the relationship, not a refusal to formulate. The goal is to make room for the child's agency while providing enough security for emotional work to proceed.

MNEMONIC

PLAY

Provide a safe frame, **L**et the child lead, **A**ttend to affect and action, and **Y**ield neither safety nor therapeutic purpose. The mnemonic describes a stance, not a script to impose on every child.

18.4 Directive play and cognitive-behavioural play therapy

Directive approaches use play to introduce, practise or rehearse a therapeutic task. The therapist may select an activity, invite role-play around a difficult interaction, or guide attention toward coping. The child remains active, but the therapist contributes more structure than in child-centred work.

Cognitive-behavioural play therapy is an example of a directive approach. Its use of **modelling** allows adaptive coping skills to be demonstrated within play. A figure, puppet, story or therapist enactment can make a coping response concrete before the child is asked to attempt it. The strength of this method is that it converts an abstract instruction into an observable sequence. The limitation is that the therapist can too easily become the author of the child's play, thereby losing the child's own language and priorities.

Directive does not mean coercive. The therapist explains the invitation in developmentally understandable language, watches whether the activity is becoming too exposing or performance-based, and changes course if the child cannot engage. The activity should serve the formulation, not prove that a manual has been followed. A child who resists a structured task may be communicating avoidance, confusion, fear of failure, a mismatch of pace, or a need for a different mode of contact. The clinical response is to understand the obstacle, not simply to increase pressure.

CLINICAL QUESTION	CHILD-CENTRED EMPHASIS	DIRECTIVE EMPHASIS
Who initiates the activity?	The child's choice and unfolding play organise the encounter.	The therapist may introduce an activity linked to a therapeutic task.
Therapist's main contribution	Presence, reflection, containment and careful following.	Guidance, rehearsal and focused use of an activity.
How is change approached?	Through expression, relationship and the child's experience of agency.	Through structured experience, practice and demonstrable coping.
Principal risk if poorly used	Confusing permissiveness with a secure therapeutic frame.	Turning the activity into adult-led instruction rather than therapeutic play.

The two positions are best understood as different therapeutic emphases, not as a contest between free play and technique. A clinician chooses and adjusts the degree of structure in relation to the child, the therapeutic task and the developing alliance. The broader principles and disorder-specific applications of cognitive behaviour therapy are addressed in the cognitive behaviour therapy and adaptations for children and adolescents section of this chapter.

TRAP **Do not call every play-based encounter "non-directive".** If the therapist selects the task, teaches a response, arranges rehearsal or steers toward a stated therapeutic target, the work is directive. The distinction matters because it clarifies what the therapist is doing and why.

18.5 Core techniques in the room

Techniques are ways of using relationship and medium, not separate treatments to apply without formulation. Tracking puts into simple language what the child is doing, offering attention without intrusion. Reflecting feeling makes emotional tone available for thought without demanding explanation. Restating a plot can help a child recognise continuity in an

overwhelming story. Silence can communicate that the child need not fill the space to keep the therapist engaged.

Role-play permits a difficult situation to be approached from more than one position. The child may assign the therapist a role, reverse roles, make a powerful character vulnerable, or try out a different ending. The therapist should accept the invitation but avoid making the scene a vehicle for adult advice. Questions can expand possibilities; a moral lecture collapses the play into compliance.

Story-making, drawing and construction can assist communication when direct speech feels too exposed. The process reveals how a child begins, persists, abandons, repairs, seeks help, tolerates mistakes and responds to attention. The clinician can use this to guide therapeutic contact, but should not claim a fixed symbolic meaning for a colour, animal, weapon, house or family arrangement. Symbolic material remains contextual and open to more than one reading.

- Use reflection to make action and affect more available for the child to notice.
- Use role-play and narrative to explore possibilities without forcing disclosure or a preferred ending.
- Use limits and repair to show that strong affect can be contained within a continuing relationship.

Work with caregivers is often necessary around the edges of play therapy. Caregivers need a plain explanation of the therapeutic purpose, a way to share relevant changes in the child's life, and guidance about how the clinical relationship will be protected. They should not be asked to interrogate the child after each meeting or demand a report of play content. At the same time, the therapist should not create secrecy that excludes caregivers from essential treatment planning. The balance is to share what is clinically necessary while respecting the child's emerging sense that the therapeutic space can be trustworthy.

GOOD TO REMEMBER

When a child offers a dramatic play scene, begin by joining the child's level of meaning: notice what happens, acknowledge the feeling if it is evident, and ask whether the child wishes to say more. An interpretation can wait. Once the therapist has imposed a story, it is difficult to know whether later material belongs to the child or to the suggestion.

18.6 Formulation, selection and indications

Play therapy is selected because play is likely to be a useful route into therapeutic work, not because the child is young or because verbal treatment feels difficult for the clinician. The formulation should ask what difficulty is being addressed, how the child currently communicates distress, what kind of therapeutic relationship is possible, and whether an expressive, relational or structured play approach fits the task. It should also identify when another intervention needs to carry the main burden of treatment, with play therapy contributing a supportive role.

The Association for Play Therapy describes use across a broad range of **indications**. These include anger management, grief and loss, divorce and abandonment, and crisis or trauma. It also includes anxiety and depression, ADHD and autism or pervasive developmental disorder, academic and social developmental problems, physical and learning disabilities, and conduct disorders. These are indications for considering play therapy as a primary or supportive intervention, not diagnostic labels made by observing play.

The list is not an automatic referral rule. A child with loss may need a relationship in which remembering and reunion can be approached symbolically. A child with anxiety may externalise a feared situation or try coping. A child with disruptive behaviour may need intervention directed at daily contingencies and caregiver responses, even if play work also helps communication. Formulation, family context and engagement determine the treatment choice.

When the concern is ADHD, its treatment is addressed in the ADHD and specific learning/communication disorders notes. When the concern is a childhood behavioural or emotional disorder, its diagnostic and disorder-specific treatment is addressed in the Child behavioural, emotional and other disorders notes. Intellectual disability and autism spectrum disorder require the broader developmental formulation set out in the Intellectual disability and autism spectrum disorder notes. These cross-references protect against using play therapy as a substitute for comprehensive assessment or disorder-specific care.

PITFALL

Do not send a child to play therapy because “the child will not talk,” without first asking what makes talking difficult and what treatment task is being proposed. Silence can reflect fear, language mismatch, developmental differences, family pressure, a distressed therapeutic alliance or simple unfamiliarity with the setting. A referral without formulation burdens both child and therapist with an unclear goal.

18.7 Limits, coordination and review

Play therapy should be reviewed as therapy, not protected from evaluation because it feels child-friendly. The clinician and therapist need a shared account of the difficulty, intended direction of change, engagement and relation to other care. Lack of progress is information: it may signal a mismatch of approach, an unaddressed contextual problem, insufficient coordination or a need to revise the formulation.

Coordination must preserve role clarity. Behaviour therapy and parent management training focus on daily contingencies; family interventions address relationship patterns; and educational, remedial, early-intervention and stimulation work address other defined needs. Play therapy may coexist with each, but its unique contribution is a therapeutic use of play within an individual relationship. Describing all child interventions as “play therapy” blurs treatment goals and makes review impossible.

There are circumstances in which the clinician must move beyond ordinary therapeutic exploration. If play raises concern about immediate harm, coercion or abuse, safety takes

precedence over completing a narrative or interpreting symbolism. The clinician should use the relevant protection pathway and avoid suggestive questioning. Detailed child-protection assessment, reporting duties and management are dealt with elsewhere in this chapter. Play therapy can support recovery, but it should not be misused as a forensic method or as a means of testing an allegation.

PLAY	RELATIONSHIP	STRUCTURE	FORMULATION
A MEDIUM FOR EXPRESSION	THE THERAPEUTIC VEHICLE	VARIES BY APPROACH	GUIDES SELECTION AND REVIEW

Play therapy is a formulated therapeutic relationship in which play helps the child express, explore and work through difficulty; the therapist follows or directs the medium only as the clinical task requires.

19 · Behaviour therapy and parent management training in children

Why it matters clinically. Behaviour therapy and parent management training translate a formulation into small, observable changes in the child's daily environment. They are not shorthand for blaming a caregiver, asking a parent to be stricter, or rewarding compliance indiscriminately. Their clinical purpose is to alter the interactional conditions that keep a problem going, while preserving the child's dignity and the caregiver's capacity to remain connected.

The marks in this area usually come from showing that the psychiatrist can move from a complaint to a workable behavioural formulation. The candidate should be able to identify the target behaviour, locate its antecedents and consequences, explain the learning principle in ordinary clinical language, and describe how caregivers will practise a consistent response. The disorders themselves, including their diagnostic thresholds and disorder-specific treatment plans, belong in the Child behavioural, emotional and other disorders notes and the ADHD and specific learning/communication disorders notes.

19.1 Scope and therapeutic stance

Behaviour therapy is a structured psychological approach that uses an agreed description of behaviour and its context to guide change. In child work, the environment is usually shared with caregivers, siblings, teachers and peers. This makes the intervention relational without turning it into family therapy: the immediate task is to change the contingencies surrounding a carefully chosen behaviour, rather than to interpret the whole family system. Family therapy and broader family interventions are considered separately in this chapter.

Parent management training places caregivers at the centre of intervention because they are the people most able to make daily routines predictable and to notice small improvements. The clinician is neither a distant expert issuing instructions nor an adjudicator deciding who is at fault. The stance is collaborative: hear what the family has already tried, acknowledge exhaustion and practical constraints, then build a plan that can be carried out in the actual home rather than in an idealised household.

A good formulation distinguishes a child's intention from the function of behaviour. A behaviour can communicate distress, obtain access to something desired, avoid an aversive demand, or recruit adult attention. These possibilities are hypotheses to test with observation, not moral labels. The same outward act may have a different function in a different setting. That is why a generic instruction such as "be consistent" is weaker than a shared, concrete plan for a particular routine.

RULE **Change the interaction around a behaviour before judging the child's character.** The useful clinical question is what happens immediately before and after the target behaviour, and what each person learns from that sequence. This directs intervention toward modifiable events and protects the alliance.

19.2 Building a behavioural formulation

The starting point is an operational description. "Does not listen" is too broad to guide treatment; it blends a caregiver's understandable frustration with several possible behaviours. The team instead agrees on what an observer would see or hear, the situations in which it occurs, and the response that will count as improvement. This language makes it possible for caregivers to notice progress and for the clinician to revise an ineffective plan without personal criticism.

Antecedents are the immediate contexts in which the behaviour is more likely to occur: transitions, demands, delay, fatigue, competition for attention, ambiguity, or an escalating adult tone. They are not excuses for harmful behaviour. They are leverage points. A plan may simplify a routine, prepare a child for a transition, offer a limited choice, or ensure that an instruction is clear enough to be followed. Such changes reduce unnecessary conflict before discipline is needed.

Consequences are what follows the behaviour and therefore shape the likelihood that the sequence will recur. The relevant consequence may be attention, access, escape, relief from a demand, or the ending of an unpleasant exchange. Caregivers often discover that an apparently sensible response is accidentally maintaining the very pattern they want to reduce. This is not a parental failure. It is the clinical finding that makes a more effective response possible.

FORMULATION ELEMENT	QUESTION FOR THE CLINICAL INTERVIEW	HOW IT INFORMS THE PLAN
Target behaviour	What would an observer describe?	Creates a shared and measurable treatment target.
Setting event	What makes the routine harder on some occasions?	Identifies preventable pressures and reasonable adjustments.
Antecedent	What happens immediately before the behaviour?	Guides preparation, clarity and environmental change.
Behaviour	What does the child actually do?	Keeps the plan observable rather than judgmental.
Consequence	What changes immediately afterwards for child and adult?	Shows what needs reinforcement, withholding or replacement.
Alternative	What safer or more workable response can be taught?	Prevents treatment becoming punishment alone.

Observation may be informal but should be purposeful. Invite caregivers to recount a recent episode in sequence, including their own words, tone and actions. Ask what happened when the child complied, not only when conflict occurred. Where a setting outside the home is important, the clinician can seek a parallel account from the adults there, while avoiding a hunt for a single "correct" informant. The formulation becomes useful when it identifies a pattern that the family themselves recognises and can modify.

Target	Context	Response	Practice
OBSERVABLE BEHAVIOUR	WHAT COMES BEFORE	WHAT FOLLOWS	NEW SHARED ROUTINE

19.3 The coercive interactional cycle

Parent-child coercive cycle is a useful description of escalating exchanges in which both people seek short-term relief. A caregiver makes a demand or attempts a limit. The child protests or escalates. The adult, faced with mounting distress, may withdraw the demand or change course. The episode ends, but the sequence has taught both participants something about how conflict can be ended. This pattern can compromise the caregiver's sense of efficacy and make the next limit harder to hold.

The central learning mechanism is not that either party wishes to create conflict. It is that disengagement in the face of escalation can be **negatively reinforcing** for the child's misbehaviour: the aversive demand disappears, so escalation becomes more likely to be used again. The adult may also experience relief when the immediate conflict stops. That reciprocal relief explains why insight alone rarely changes the pattern. A different response has to be rehearsed before the next pressured moment.

The treatment aim is not stubborn endurance. It is planned, calm and proportionate follow-through, coupled with frequent attention to the behaviour the caregiver wants to see more often. When the proposed demand is unrealistic, the correct intervention may be to alter the demand.

When the boundary is necessary, the caregiver needs a brief response that does not accidentally turn escalation into negotiation. The psychiatrist helps the family discriminate these situations, because rigid application of a technique can intensify distress or rupture trust.

GOOD TO REMEMBER

When a caregiver says, "Nothing works," first ask what happens immediately after the child escalates. That question often reveals both the family's strain and the point at which a new response can be practised.

TRAP **Do not equate behaviour therapy with a harsher punishment plan.** A plan that focuses only on stopping undesirable behaviour often misses antecedents, fails to teach an alternative, and gives too little attention to cooperation. The clinical skill is contingency management with warmth, clarity and repair.

19.4 Core components of parent management training

Parent management training converts the formulation into skills that can be used under ordinary domestic pressure. The clinician selects a small set of targets, demonstrates the skill, invites rehearsal, anticipates obstacles and reviews what happened. The sequence matters. Information without rehearsal is easily understood in the consulting room and lost in a difficult bedtime or school-morning routine.

- Specify the behaviour to increase or decrease in plain, observable terms.
- Arrange the setting so that cooperation is possible before giving a demand.
- Use brief, calm and unambiguous instructions, with a realistic opportunity to comply.
- Notice and respond promptly to desired behaviour, including small approximations to the target.
- Choose a predictable response to the target problem behaviour that does not inadvertently reward it.
- Review the outcome without shaming the child or caregiver, then adjust the plan.

Reinforcement is often misunderstood as bribery. Clinically, it means arranging consequences so that adaptive behaviour becomes more likely to recur. It works best when the behaviour is clearly identified, the response is linked closely to it, and the caregiver's attention is credible rather than mechanical. Genuine descriptive praise can be especially useful because it tells the child what was done well and strengthens the relationship at the same time.

Responses to problem behaviour must be selected from the formulation, not applied as ritual. A response that reduces attention may be appropriate only when attention is maintaining the behaviour and when safety is secure. Removal of a privilege may be meaningful only if it is realistic, proportionate and not silently reversed during conflict. The child also needs an alternative route to attention, choice, help or escape from an overwhelming demand. Otherwise the plan removes a behaviour without creating a workable replacement.

MNEMONIC

Notice - Name - Nurture - Navigate

Notice the sequence, **name** the target behaviour, **nurture** the behaviour worth repeating, and **navigate** predictable conflict without abandoning the plan or the relationship.

19.5 Delivery, participation and review

For conduct-related presentations, NICE recommends offering a group parent-training programme to the parents of children aged between **3 and 11 years** when there is identified risk or established oppositional, conduct or antisocial difficulty. This is an indication for a structured parent intervention, not a substitute for a full clinical formulation. Comorbidity, developmental profile, safety concerns, caregiver mental health, substance use, domestic stress and the child's wider supports all affect whether a group format can be used as planned.

The programme model specified by NICE is a **social learning model**, using modelling, rehearsal and feedback. A typical programme has **10 to 16 meetings**, each lasting **90 to 120 minutes**. These features are worth remembering because they distinguish a genuine skills programme from general advice. They also explain why participation needs active support: caregivers have to observe a skill, try it, report the outcome and receive constructive feedback.

Group work offers normalisation and opportunities to learn from other caregivers, but it should not make a family invisible. The facilitator must be alert to caregivers who feel exposed, who cannot safely practise a recommended response, or whose literacy, language, work pattern or travel make participation difficult. A flexible clinical service may use individual contact, a different delivery format, or coordination with other supports, while retaining the same behavioural logic. Practical adaptation is not dilution when it preserves the treatment mechanism.

IN INDIA

Parent work is most useful when the plan is fitted to the household that exists: who actually cares for the child, which language carries authority and affection, how school expectations enter the routine, and what material pressures limit follow-through. Avoid importing a scripted programme unchanged. Adapt examples and homework collaboratively, while keeping the target behaviour and response plan clear.

Review is a clinical intervention, not merely an attendance check. Ask what was attempted, what the child did, what the adult did next, and what made success easier or harder. Look for improvement in the interaction before expecting every target behaviour to vanish. If a plan has not worked, return to the formulation: the target may be too broad, the antecedent may have been missed, the chosen consequence may not matter to the child, or caregivers may need more rehearsal and support.

PITFALL

Do not interpret non-completion as lack of motivation. A caregiver may be unable to attend or practise because of shift work, transport, crowded living conditions, competing care responsibilities or fear of criticism. Explore the barrier directly, then decide whether the intervention needs adaptation or additional support.

19.6 Boundaries, integration and referral thinking

Behavioural work is strongest when it is embedded in a broader child psychiatric plan rather than presented as a universal answer. The clinician should consider whether pain, sleep disruption, communication difficulty, learning problems, trauma, mood symptoms, neurodevelopmental differences, medication effects or environmental adversity are changing the child's capacity to respond. Naming these possibilities does not mean re-teaching their assessment or treatment here; it means refusing a simplistic formulation when the behavioural pattern is a signal of something else.

Behaviour therapy may be coordinated with school support, individual psychological work or other family interventions, but each contributor should know the target and avoid giving contradictory advice. Where the child's safety is at risk, where there is abuse or coercion within the caregiving environment, or where a caregiver cannot safely implement a plan, the priority changes from routine behaviour management to protection and appropriate multidisciplinary action. The clinical safeguarding response is addressed elsewhere in this chapter.

For children with intellectual disability or autism spectrum disorder, behavioural principles may still inform daily supports, but diagnostic formulation and the wider developmental intervention belong to the Intellectual disability and autism spectrum disorder notes. For attention-related presentations, disorder-specific assessment and medication decisions belong to the ADHD and specific learning/communication disorders notes. The value of parent management training here is its disciplined focus on observable interaction, not an attempt to make one method cover every need.

Formulate the sequence, strengthen the behaviour you want repeated, and help caregivers respond predictably enough that escalation no longer becomes the easiest route out of conflict.

20 · Family therapy and family interventions in child psychiatry

Why it matters clinically. A child's difficulty is lived in relationships long before it is described in a consultation. Family work therefore asks not only what is troubling the child, but what happens around the difficulty: who notices it, who responds, who is drawn into an argument, who withdraws, and what relief follows. This is not a search for a culpable relative. It is a way of understanding how a family's ordinary attempts to cope may inadvertently keep a problem active, and how the same family can become the chief resource for change.

For the psychiatrist, **family intervention** is both a treatment and a clinical stance. It makes room for the child's developmental dependence, the authority and burden carried by caregivers, and the practical realities that shape whether any plan can be carried home. It is especially useful when a child's difficulty has become organised around conflict, avoidance, inconsistent responses, divided caregiving, or a narrowing of the child's role within the household. The task is to restore useful relationships and workable caregiving, while preserving the child as a person rather than reducing the child to the family's symptom.

SYSTEM	PATTERN	CHANGE
RELATIONSHIPS MATTER	MAP WHAT REPEATS	PRACTISE IT IN SESSION

20.1 Scope and therapeutic stance

Family therapy is not a single technique applied whenever relatives are present. It is a way of working in which the unit of attention shifts between the child, the caregiver, the relationship, and the wider household context. The psychiatrist needs a clear reason for making that shift. A consultation may require brief work to align caregivers around a plan, sustained work on interactional patterns, or careful liaison when a child cannot safely be asked to carry a family conflict. The intensity and format should follow the formulation, not the therapist's preferred school.

A useful **family formulation** links the presenting difficulty to reciprocal responses. It asks what tends to precede an episode, how each person understands it, what each person does next, and what consequence makes that response likely to recur. Such a formulation remains provisional. It must accommodate developmental level, communication ability, physical illness, learning needs, stress, separation, and the child's own account. A relational account that ignores the child's individual experience is as incomplete as an individual account that ignores the household in which care is delivered.

Neutrality is often misunderstood as emotional distance or as pretending that every action has the same effect. In practice it means respectful curiosity toward each participant's position. The clinician can acknowledge a caregiver's exhaustion, a child's fear, and another family member's wish to help without endorsing harmful conduct or making the child responsible for adult distress. This stance reduces defensiveness and permits difficult material to be discussed. It also protects against the familiar error of treating the most articulate adult as the sole narrator of family life.

RULE **Formulate a pattern, not a culprit.** The clinical question is how responses connect and persist, while keeping the child's safety, experience, and developmental needs in view.

20.2 Mapping the family pattern

The opening phase is active clinical enquiry, not a social history recited for formality. Ask who is involved in daily care, who makes decisions, where authority sits, how transitions are managed, and how conflict is repaired. Notice alliances, exclusions, abrupt changes of topic, and whether the child is expected to speak only through an adult. Ask each person for a concrete account of a

recent difficult interaction. General descriptions such as “he never listens” or “she is always stubborn” often conceal an interactional sequence that becomes visible only when reconstructed in detail.

A **transactional sequence** is clinically more useful than a global label. The clinician follows the exchange from the first cue through each response to the eventual outcome. Attention to sequence reveals points where a different response could interrupt escalation. It also shows the function of behaviour in context without declaring that the child is deliberately manipulating the family. The purpose is explanatory precision, not moral judgement.

The interview should include the child in a manner that is comprehensible and emotionally safe. Direct questions can be paired with observation of how adults respond when the child speaks. The clinician may ask caregivers to describe what they believe the child is trying to communicate, then invite the child to correct or add to that account. This both gathers information and begins to alter an entrenched pattern in which the child is spoken about but not heard. Equally, a child should not be recruited to reveal private adult material or to decide between caregivers.

- Identify the concern in the family’s own language before translating it into clinical terms.
- Trace a recent interaction from trigger to consequence, rather than relying only on trait descriptions.
- Attend to participation: who speaks, who answers for whom, and whose view is absent.
- Clarify strengths, routines, and moments when the difficulty is less dominant.

> **GOOD TO REMEMBER**
>
> When a caregiver asks for the clinician to “fix the child,” hear the request for relief but widen the task gently. A useful response is to make the child’s distress important while inviting the adults to examine what they can change around it.

20.3 Structural thinking: subsystems and boundaries

Family subsystems allow a family system to differentiate and carry out its functions. In clinical work, this directs attention to the organisation of participation and responsibility rather than to personalities alone. A caregiver relationship may need room to coordinate care; children may need space for age-appropriate relationships; and the child should not be placed in an adult role simply because the family is under strain. The psychiatrist assesses these arrangements by observing interactions and by asking how decisions are actually made, not merely how the family says they ought to be made.

Boundaries are the rules within a subsystem that determine who takes part in a situation, when participation occurs, and how it occurs. They are best understood as functional patterns, not as fixed virtues. A boundary may be too permeable for a particular task, leaving a child exposed to adult conflict, or too rigid, preventing support from reaching someone who needs it. The clinical aim is not to impose an ideal household design. It is to help the family create enough clarity, protection, and flexibility for caregiving and development.

Structural observations are hypotheses to test collaboratively. If a caregiver repeatedly answers a child's questions, the clinician should not immediately infer domination. The behaviour may reflect anxiety, habit, language difficulty, fear of being misunderstood, or a response to earlier crises. The therapeutic conversation tests meaning and effect: what happens when the child is given room to answer; what makes that difficult; and what support would make a small change possible. This protects structural work from becoming a set of labels applied to families.

TRAP **Do not turn structural language into a verdict on a family.** Terms such as boundaries and subsystems organise observation; they do not excuse a clinician from hearing context, checking hypotheses, and treating each family member with respect.

20.4 Conduct of the therapeutic meeting

The meeting is both an assessment setting and a place where change can be rehearsed. The therapist establishes a clear frame: the purpose of the conversation, how each person will be invited to contribute, and what will happen if discussion becomes overwhelming. The clinician's authority is used to slow accusation, protect the child from being made a messenger, and make room for quieter participants. This is not passive chairing. It is deliberate management of the interaction so that the family can experience an alternative to its usual sequence.

Enactment means inviting family members to address a relevant issue with each other in the session rather than only reporting it to the clinician. It provides direct information about pace, tone, interruption, authority, and repair. It also lets the therapist coach a small, observable change while the interaction is live. The invitation must be graded to tolerance. Pushing a family into emotionally charged material without preparation can produce compliance in the room and collapse outside it. A modest exchange that can be repeated safely is more therapeutic than a dramatic confrontation.

Reframing changes the meaning attached to behaviour without denying its impact. A caregiver's repeated checking might be recast as an attempt to protect that has become constricting; a child's withdrawal might be understood as a signal of overload rather than simple defiance. A good reframe reduces blame and opens alternatives. It is not a clever explanation imposed by the therapist. If the family does not recognise itself in the reframe, the clinician should revise it rather than defend it.

Tasks between meetings should be concrete, proportionate, and linked to the observed pattern. They are experiments, not tests of obedience. The next meeting examines what happened, what made change easier or harder, and what the result teaches the family about its pattern. When a task has not been attempted, the response should be curiosity rather than rebuke. Non-completion may reveal that the task was unrealistic, that the family's formulation differs from the therapist's, or that an unspoken barrier requires attention.

MNEMONIC

MAP the meeting

Make room for each voice, **A**ttend to the live interaction, and **P**ractise a manageable alternative. It is a practical spine for keeping the session relational rather than turning it into parallel individual interviews.

20.5 Strategic and problem-focused work

A strategic family approach is **present problem-focused**, **directive**, and **practical**. Its clinical appeal in child psychiatry is that it keeps attention on the current interactional pattern that accompanies the referral concern and asks for observable changes. Direction is not synonymous with coercion. The therapist remains accountable for explaining the purpose of an intervention, inviting concerns, and adapting the plan to the family's capacity and safety.

Problem-focused work is most useful when the family can identify a specific interaction they want to change. The clinician clarifies the shared aim, identifies the sequence that blocks it, and collaborates on an alternative response. Progress is judged by whether the family can use a more helpful pattern in ordinary circumstances, not by whether they can reproduce the therapist's language. The approach should not flatten complex grief, trauma, coercion, or severe adversity into a simple communication problem. Where these are present, pace, protection, and appropriate parallel care take priority.

The psychiatrist should distinguish a directive that changes an interaction from advice that merely sounds firm. Vague instruction can leave caregivers feeling blamed for failing to implement an undefined plan. Conversely, overly prescriptive advice may disregard the realities of work, housing, illness, and extended-family influence. Good direction is specific enough to try, flexible enough to revise, and anchored in the family's own stated goal.

20.6 Integrating family intervention with child care

Family work should sit within a coherent treatment plan, not compete with it. The psychiatrist makes explicit what family sessions are intended to change and what they are not intended to replace. Individual psychological work, behavioural intervention, educational support, medication decisions, and safeguarding processes each have their own indications and limits. They can be coordinated around a shared formulation without being collapsed into a single intervention. The childhood disorders themselves are addressed in the Child behavioural, emotional and other disorders notes; intellectual disability and autism spectrum disorder are addressed in the Intellectual disability and autism spectrum disorder notes.

Coordination requires careful communication. Caregivers need to know why more than one professional may be involved and how information will be shared. The child needs an account that is truthful, developmentally understandable, and respectful of privacy. When parents or caregivers disagree, the clinician should not privately recruit one side into a therapeutic alliance. Instead, name the disagreement, clarify which decisions need a shared plan, and preserve a space

for the child's interests. A family meeting is not automatically appropriate merely because family conflict exists.

CLINICAL QUESTION	FAMILY-THERAPY RESPONSE	WHAT THE PSYCHIATRIST MONITORS
What has become stuck?	Map the recurring interaction.	Whether the account includes every relevant voice.
What role is the child carrying?	Examine participation and responsibility.	Whether adult conflict is being placed on the child.
What can change at home?	Rehearse a manageable alternative.	Whether the task is safe and feasible.
What requires another response?	Coordinate rather than overextend family work.	Whether protection, individual care, or practical support is needed.

Confidentiality needs thought before the first emotionally charged disclosure. The clinician should explain the practical limits of private conversations and avoid making promises that cannot be honoured. Separate conversations may sometimes be clinically necessary, but hidden coalitions can make relational work unsafe or ineffective. Where there are concerns about violence, coercion, abuse, or serious intimidation, the priority is protection and an appropriate safeguarding response, not joint exploration of the relationship.

20.7 Indian clinical practice and service realities

IN INDIA

Family participation is often central to how a child reaches care and whether a plan can be implemented. Use that strength without assuming that every relative should be in the room or that the loudest family member represents the child's interests. Ask explicitly who the child trusts, who provides daily care, and who can support a realistic change between appointments.

In an Indian setting, the family meeting may include people whose authority is practical, emotional, or financial rather than formally parental. This can be valuable when it broadens support, but it may also silence the child or overwhelm a caregiver. The clinician should decide attendance by therapeutic purpose. A meeting to support a caregiver may need a different membership from a meeting intended to reduce a child's exposure to conflict. Cultural humility does not mean accepting hierarchy as an explanation for avoidable distress; nor does it mean importing an individualistic model that ignores interdependence and care.

Language is a clinical tool. Family therapy concepts should be expressed in words that participants can use outside the clinic. Translating a formulation into everyday language helps a family notice the pattern without turning clinical terminology into another source of shame. It is also worth checking that agreement is genuine. Polite assent in a consultation may conceal confusion, fear of contradicting an elder, or an impractical burden placed on one caregiver.

PITFALL

Do not mistake family involvement for family consent to disclose everything. Bringing relatives into care does not remove the need to protect the child's privacy, to ask about safety, or to consider whether a joint meeting could increase pressure on the child.

20.8 Limits, safety, and the examination answer

Family therapy has limits. It is not a neutral container for situations in which a child or caregiver may be harmed by speaking openly. It should not be used to mediate abuse, to obtain a child's disclosure in front of a potentially unsafe person, or to distribute responsibility for adult violence onto the child. In such circumstances, the clinician must shift from relational exploration to protection, follow the relevant service pathway, and use a child-centred clinical response. The statutory and safeguarding framework is addressed in the child-protection sections of this chapter.

A strong written answer begins with the systemic rationale, then shows how the therapist assesses patterns, participation, and boundaries. It explains how an interaction is brought into the room, how a small alternative is practised, and how the work is integrated with the wider plan. It should state plainly that family work is collaborative, non-blaming, and contingent on safety. The answer gains depth when it distinguishes observation from interpretation: seeing a child interrupted is an observation; deciding why it occurs requires enquiry and hypothesis testing.

Family intervention changes the conditions around a child's difficulty by helping the family see, test, and sustain a safer and more workable pattern of care.

21 · Cognitive behaviour therapy and adaptations for children and adolescents

Cognitive behaviour therapy is a way of making change visible, testable and usable. In child psychiatry, it is not a smaller version of adult psychotherapy delivered with simpler words. It is a collaborative, structured intervention in which the clinician helps a young person notice links between situations, meanings, feelings, bodily states and actions, then practise alternatives in ordinary life. Its value lies in converting an overwhelming, global problem into a formulation that can be shared, revised and acted upon.

The examination answer should therefore show more than a list of techniques. It should explain how developmental capacity, language, play, family context and school demands alter the delivery of CBT. The therapist remains active, but does not become a lecturer or an external disciplinarian. The work is designed so that the child or adolescent can increasingly recognise a pattern, generate a manageable alternative and learn from the result. Disorder-specific indications and protocols belong in the relevant disorder chapters; this section concerns the therapeutic method and its developmental adaptation.

21.1 The therapeutic stance and cognitive formulation

Cognitive behaviour therapy begins with the proposition that distress is shaped not only by events but also by the meaning assigned to them and by the response that follows. This is not an

invitation to tell a child that their problem is imaginary or that they ought to think positively. A formulation asks what happened, what the young person noticed, what they made of it, what they felt in mind and body, what they did next, and how that response altered the situation. It preserves the reality of adversity while identifying points at which agency may be restored.

A useful **cognitive formulation** is a working map, not a diagnostic label and not a verdict on the child. It should be expressed in language the child can recognise, checked against concrete examples, and modified when it fails to fit. The therapist listens for recurring predictions, self-statements, rules and interpretations, but also for avoidance, reassurance seeking, withdrawal, impulsive responding and other behaviours that may bring immediate relief while preserving the difficulty. The formulation makes these patterns discussable without making the child feel blamed for them.

Children often communicate the relevant meanings indirectly. A drawing, game, recent disagreement, bodily complaint, or account of a difficult school moment may offer a better route into the formulation than an abstract question about beliefs. Adolescents may tolerate more direct reflection, but apparent verbal sophistication should not be mistaken for emotional readiness. The clinician tests understanding rather than assuming it, and deliberately separates a thought from a fact, a feeling from an instruction, and a feared possibility from a certainty.

RULE **Formulate with the young person rather than explaining the young person to themselves.** A shared map gives techniques a purpose and lets the child correct the therapist's assumptions.

Collaboration also changes the handling of disagreement. If the child rejects the therapist's account, the task is to find the missing context, not to persuade them into compliance. A parent may describe a behaviour as defiance while the child describes it as panic, humiliation or unfairness. Both accounts can be explored, provided the session does not turn into a tribunal. CBT is strongest when it makes competing accounts testable and when its language remains respectful of the child's experience.

A formulation ready for treatment should make clear:

- the situations in which the difficulty is most likely to occur;
- the meanings and responses that appear to keep it going; and
- a change target that the young person can recognise as relevant.

21.2 From formulation to behavioural learning

CBT is maintained by doing, observing and reviewing. Discussion can open a door, but change usually requires action outside the consulting room. The therapist and young person select a task that is understandable, relevant and within reach. The task should test a prediction, practise a coping response, or interrupt a maintaining pattern. Its result is then reviewed with curiosity. A task that did not go as hoped is information for revising the formulation, not evidence that the child has failed treatment.

Behavioural experiments are especially useful because they replace argument with learning. Rather than assure a young person that a feared outcome will not occur, the clinician helps them state the prediction, identify what would count as evidence, and observe the outcome. The exercise must be proportionate and safe. It is not an ordeal arranged to prove bravery, nor is it an adult's test of obedience. The child needs to know why the task was chosen, what support is available, and how the experience will be discussed afterward.

Graded practice is the developmental answer to the common error of asking for too much too soon. Difficult tasks are broken into meaningful steps, with the pace set by learning rather than by adult impatience. Repetition matters because a new response becomes credible when the young person has experienced it in varied contexts. Where avoidance is prominent, the therapeutic target is willingness to approach a valued or necessary activity while using skills, not the elimination of every uncomfortable feeling before action begins.

THERAPEUTIC ELEMENT	QUESTION FOR THE THERAPIST	DEVELOPMENTALLY ADAPTED DELIVERY
Situation	What was happening just before the difficulty?	Use a recent scene, picture, role play or game rather than a remote summary.
Meaning	What did the child think the situation meant?	Invite speech, drawing, choice cards or enacted alternatives.
Emotion and body	How was distress recognised?	Link words to faces, body cues, movement and familiar experiences.
Response	What happened next?	Rehearse a different response in session before asking for practice elsewhere.
Review	What was learned from trying it?	Use a brief, concrete review that credits effort and notices obstacles.

Behavioural activation is another way of restoring contact with activity, mastery, pleasure or connection when the young person has become narrowed by distress. The therapist explores what has fallen away and what might be reintroduced in a realistic form. The point is not to prescribe busyness. It is to create experiences that can challenge hopeless conclusions and provide opportunities for reinforcement. Family routines and school demands may either support this work or quietly defeat it, so they need to be considered in the plan.

TRAP **Do not mistake a worksheet for CBT.** A completed form has no therapeutic value unless it is understood, linked to an individual formulation, followed by practice, and reviewed for learning.

21.3 Developmental adaptation as a clinical skill

Developmental adaptation concerns the entire therapy, not merely the vocabulary of the handout. The child must be able to grasp the task, hold it in mind, relate it to a real situation and use it when the therapist is absent. The clinician therefore adjusts the level of abstraction, pace,

method of expression, amount of scaffolding and expected independence. This is a matter of access and therapeutic fidelity, not dilution of treatment.

With younger children, the work often needs to be anchored in the here and now. Thoughts may be introduced as speech bubbles, characters, detective clues, or alternative endings to a story. Feelings can be represented through faces, colours, body outlines or a simple scale without demanding a polished verbal narrative. Role play permits rehearsal of a response before the child has to use it in a consequential setting. Play is used purposefully: it creates psychological distance, reveals a pattern and enables practice. The principles and techniques of play therapy itself are addressed separately in the play therapy section.

Attention, memory, literacy, communication style and sensory needs all affect whether a task is usable. Instructions may need to be brief, concrete and repeated in the child's own words. Visual prompts can be co-created rather than handed down as schoolwork. A young person who cannot record a thought in writing may still notice it through speech, drawing or a cue agreed with the therapist. The therapeutic question is always: what format lets this child demonstrate understanding and practise the intended skill?

Before setting practice, the therapist checks whether the task:

- has a purpose the child can state;
- can be carried out in the setting where it matters; and
- has a review plan that treats obstacles as information.

Parents or carers often serve as **therapeutic coaches**. They can help notice opportunities for practice, reduce unhelpful accommodation, reinforce effort and bring observations back to the session. Their participation should be transparent to the child and bounded by the treatment rationale. If the adult takes over the monitoring, answers every question, or turns homework into surveillance, the work loses the child's ownership. Parent management training has its own methods and indications; CBT uses caregiver involvement to support the young person's formulation and skill use.

MNEMONIC

MAP

Make it concrete, **A**ctively rehearse it, **P**lace practice in the child's everyday world. This is a delivery check, not a substitute for formulation.

Guidance for children aged **5-11** with mild depression that continues after **2 weeks of watchful waiting**, and without significant comorbid problems or active suicidal ideas or plans, asks clinicians to consider psychological options, including CBT, **adapted to developmental level as needed**. The practical implication is important: developmental adaptation is not an optional embellishment added after a standard protocol has failed. It belongs in treatment selection, explanation, materials, tasks and review from the outset.

GOOD TO REMEMBER

If a child repeatedly cannot complete a task, first reconsider the task's developmental fit, clarity and environmental support. Escalating pressure may teach shame rather than skill.

21.4 Working with adolescents without becoming didactic

Adolescence permits greater use of reflection, self-monitoring and discussion of long-term consequences, but these capacities are uneven and context-sensitive. The therapist should not confuse an adolescent's ability to debate an idea with readiness to test it in a difficult social setting. Privacy, autonomy and the wish not to be managed by adults are clinically relevant. A collaborative agenda, clear explanation of what will be shared with carers, and genuine choice about between-session practice help preserve engagement.

Guided discovery is preferable to cross-examination. The clinician asks questions that help the adolescent examine an interpretation, identify an exception, compare alternatives and decide what experiment would be fair. This approach respects intellect while avoiding a contest about who is right. It also makes room for structural problems such as conflict, exclusion, academic pressure or unsafe environments. CBT can clarify what is modifiable without implying that the young person is responsible for adversity around them.

Digital communication can be incorporated as content where it is central to the young person's experience, but it should not automatically become the medium of therapy. The clinician considers privacy, misunderstanding, family access and whether a digital task will increase monitoring rather than learning. The durable therapeutic aim remains the same: to help the adolescent carry a flexible formulation and tested coping responses into ordinary relationships, education and daily routines.

21.5 Family, school and the treatment environment

CBT takes place in an ecology. A child may leave a useful session and return to routines that reward avoidance, amplify threat, make practice impossible or communicate that distress is a moral failure. The clinician asks which adults and settings need a shared understanding of the treatment goal. This does not mean recruiting every adult into therapy. It means choosing supports that protect practice while preserving the child's dignity and confidentiality.

Communication with school is most useful when it is specific to function: what helps the student begin a task, use a coping plan, return after distress, or avoid being singled out. It should not become a broad disclosure of private therapy content. Educational and remedial interventions are addressed separately in the special education and educational interventions section. Likewise, where family patterns themselves require therapeutic work, the reader should refer to the family therapy and family interventions section rather than relabel family therapy as CBT.

IN INDIA

Developmentally adapted CBT may need to move flexibly between the language of the child, caregiver and school. Materials that fit the family's daily routines and preferred language are often more usable than imported worksheets. Explain the formulation in plain, non-stigmatising terms, and agree in advance what information may be shared with teachers or extended family.

PITFALL

Translating a worksheet word for word is not the same as adapting therapy. If its examples, literacy demands or assumptions about privacy do not fit the child's setting, the form can make the young person appear uncooperative when the intervention is actually inaccessible.

21.6 Reviewing progress, obstacles and scope

Review is part of the intervention, not an administrative ending. The therapist asks whether the formulation still fits, whether the child understands the skill, whether practice occurred in the intended context, and what blocked it. A lack of progress may reflect an inaccurate formulation, insufficient developmental adaptation, competing stressors, an unhelpful family response, poor fit between task and setting, or a need for a different therapeutic emphasis. It should not automatically be attributed to lack of motivation.

Outcome monitoring is most helpful when it is tied to the goals the child and family can recognise: greater participation, more flexible responding, recovery after distress, improved use of coping plans, or a meaningful activity regained. The young person's own account should remain central even when adult observations are also useful. General principles of child psychiatric assessment and multi-informant work are covered in the child psychiatric history and examination section and the multiaxial and multi-informant assessment section.

CBT also has limits of scope. It cannot make an unsafe environment safe, substitute for protection when there is abuse, or resolve every social and educational barrier through individual effort. When safety concerns arise, the clinical safeguarding response belongs to the child abuse management section, with the statutory reporting framework addressed in the POCSO Act section. When the principal difficulty is a childhood disorder, the relevant formulation and disorder-specific treatment should be taken from the Child behavioural, emotional and other disorders notes, the ADHD and specific learning/communication disorders notes, or the Intellectual disability and autism spectrum disorder notes as appropriate.

Developmentally adapted CBT keeps the formulation and therapeutic aim intact while changing the route by which the child can understand, practise and own the work.

MAP	TEST	SHARE	REVIEW
MAKE THE TASK CONCRETE	LEARN FROM PRACTICE	USE SUPPORTS WITH CONSENT	REVISE THE FORMULATION

22 · Special education and remedial and educational interventions

Education is a clinical outcome. A child may improve in clinic yet remain excluded from learning if school cannot use those gains. Special education, remedial teaching and educational interventions translate a clinical formulation into opportunities to participate, learn, belong and progress. The psychiatrist is not the child's teacher and a diagnosis is not an educational prescription. The task is to identify school barriers, help family and school agree on a response, and review whether it helps.

Marks are usually earned by making distinctions. **Special education** concerns planned teaching and support for a learner whose needs cannot be met adequately by ordinary classroom provision alone. **Remedial teaching** targets a defined gap in an academic skill through explicit, graduated teaching. **Educational intervention** is the wider bridge between the child, curriculum, classroom, family and service system. These overlap but are not interchangeable. A sensible plan protects access without confusing poor attainment with laziness, low expectations, a psychiatric diagnosis, or a permanent verdict on ability.

22.1 Educational formulation: from complaint to participation

The presenting complaint is often deceptively brief: the child is “not coping”, “slow”, disruptive in class, avoiding schoolwork, or repeatedly sent out of the room. Such phrases identify a problem but not its mechanism. The educational formulation asks what the child is being asked to do, at what point performance breaks down, what the child does next, and how adults respond. It examines the fit between the learner and the demands of the setting rather than locating the whole problem within the learner.

This formulation is functional and prospective. It should specify strengths that can be used in teaching, the task that currently defeats the child, conditions that improve performance, and obstacles that recur across lessons or settings. Relevant observations may include the child’s response to spoken instruction, written work, transitions, peer demands, sensory load, pace, correction and evaluation. The educational report should convert these observations into practical requests. “Needs support” is too vague to guide a teacher; a description of the condition under which the child can start, sustain and complete a task is useful.

- Define the educational concern in observable terms, including what the child can already do independently.
- Identify the demand, trigger or environmental feature that exposes the difficulty.
- State the support to be tried, who will provide it, and what change would count as improvement.

RULE **Prescribe an educational response to a functional barrier, not to a diagnostic label alone.** A diagnosis may clarify likely needs, but it does not tell a teacher which task to alter, what support to provide, or how to know that the alteration has worked.

The psychiatric assessment provides essential context, but the general framework for child psychiatric assessment belongs in the chapter on assessment. Here, the crucial move is

translation. Symptoms, developmental profile, communication style, family stress and school observations must become an educational hypothesis that the people around the child can test. This protects against both extremes: making the school responsible for everything, and assuming that medication or clinic-based therapy alone will restore participation.

22.2 Special education and the continuum of support

Special school is one possible setting, not a synonym for educational care. The central question is the adequacy of support, participation and learning for this particular child. A child may need changes in instruction, classroom organisation, communication, materials, assessment or adult support. Some children also need a setting with specialised teaching. Placement should arise from an individual educational plan, not from the convenience of the institution, the discomfort of peers, or a belief that one setting is inherently superior.

APPROACH	PRIMARY QUESTION	TYPICAL CLINICAL CONTRIBUTION	COMMON MISUSE TO AVOID
Universal classroom support	Can ordinary teaching be made more accessible?	Describe environmental and communication needs.	Calling ordinary flexibility "special education".
Targeted educational support	Which specific barrier needs additional teaching or scaffolding?	Clarify the functional target and review progress.	Offering generic extra work without a hypothesis.
Special education	What planned, specialised provision is required for meaningful participation?	Support an individualised plan and coordination.	Equating specialised provision with segregation.
Remedial teaching	Which academic skill requires direct, graduated instruction?	Distinguish a skill gap from a broader participation problem.	Using repeated drilling as the only response.

An individual educational plan is most useful when it is brief enough to be used and precise enough to guide action. It should identify priority learning and participation goals, adaptations, responsibility for implementation, communication with family, and a method of review. Goals should describe a valued function, not merely adult compliance. For example, the aim is not simply that a child remains silent or seated; it is that the child can engage safely and productively with the learning activity.

Access does not mean lowered expectation by default. An accommodation changes the route by which a child can show learning or participate. A modification changes what is expected to be learned or demonstrated. Either may sometimes be appropriate, but they should not be used casually. The psychiatrist should ask whether a proposed change removes an irrelevant barrier, or whether it unintentionally removes the educational opportunity itself. This distinction is especially important when families are desperate for relief and schools are under pressure to manage a classroom.

TRAP **Do not treat "inclusive" as a mere place name.** Physical presence in an ordinary classroom without accessible teaching, peer participation or a responsive plan can be exclusion in another form. Conversely, a specialised setting is not automatically a failure if it genuinely meets the child's educational needs and respects family choice.

22.3 Remedial teaching as a clinical partnership

Remedial work begins with a narrow, teachable target. The target may concern understanding instruction, reading, writing, numeracy, organisation, task initiation or persistence, but it should be phrased in terms that permit the teacher and family to observe progress. A broad complaint such as "poor studies" is not a target. It may conceal an instruction-comprehension problem, a gap in prior learning, a mismatch between language of teaching and language of understanding, emotional avoidance, repeated failure, irregular attendance, or an unrecognised need for a different method of communication.

The teaching response should therefore be explicit and graded. The skill is broken into manageable steps, the child is given enough opportunity to practise successfully, feedback is immediate and specific, and the level of support is adjusted as competence grows. Teaching must be humane: repeated exposure to tasks at which the child predictably fails is not remediation. The child needs an experience of mastery, while adults need evidence about which component of the task remains difficult.

- Choose a priority skill that matters to the child's current participation.
- Start from a task the child can enter with support, then make the next step visible and achievable.
- Record the child's response and alter the teaching method when progress does not occur.

GOOD TO REMEMBER

A referral for remedial teaching is more useful when it states the functional question for the educator. "Please assess the child's learning needs and advise teaching strategies" is weaker than describing the task, the observed barrier, the strengths to build on and the outcome the family and school want to see.

Psychiatric symptoms can alter availability for learning. Anxiety, mood symptoms, sleep disturbance, medication effects, family conflict or repeated peer adversity may reduce attendance, concentration, confidence or persistence. The educational plan should acknowledge these influences without turning each academic difficulty into a psychiatric symptom. When the concern suggests a childhood disorder or a specific learning or communication difficulty, the diagnostic teaching belongs in the relevant disorder chapters, including *the ADHD and specific learning/communication disorders notes*, *the Child behavioural, emotional and other disorders notes*, and *the Intellectual disability and autism spectrum disorder notes*.

22.4 Classroom adaptations and educational participation

Many adaptations are low technology and depend more on consistency than on specialist equipment. They may include making instructions concrete, presenting one step at a time,

demonstrating before expecting independent work, using visual supports, allowing a different mode of response, reducing unnecessary copying, arranging predictable transitions, offering a quiet route back into a task, or providing planned breaks. The rationale must be clear. Adaptations should reduce a barrier while preserving the learning purpose wherever possible.

The teacher's observations are clinical data when they are specific. "Does not listen" may mean that the child loses the instruction in a noisy group, cannot hold a long sequence in mind, does not understand the language used, is fearful of public correction, or has learned that disengagement prevents humiliation. A good psychiatrist does not adjudicate this from the consulting room. Instead, the report asks the school to observe the child under defined conditions and makes it safe for the teacher to report what is not working.

PITFALL

Do not write a certificate that lists a diagnosis and simply instructs the school to "give concessions". Such language is easily interpreted as either a demand for lowered standards or a document to be filed without action. Name the functional barrier and the proposed support, while leaving detailed curriculum planning to the education team.

Peer participation also matters. Educational success is diminished if the child receives individual help at the cost of stigma, isolation or loss of agency. A plan should anticipate how support will be offered respectfully, how the child will be included in ordinary routines, and how adults will respond to misunderstanding or ridicule. These are not cosmetic matters. Belonging affects willingness to attempt difficult work, accept help and return to school after failure.

22.5 Working with family, school and the child

Educational intervention is a collaborative treatment. The child should be heard about what feels difficult, helpful, embarrassing or unfair; this prevents adults from designing a technically sound plan that the child cannot tolerate. Parents bring knowledge of strengths, language, routines and prior attempts. Teachers bring knowledge of curricular demands and classroom reality. The special educator or remedial teacher brings expertise in teaching method. The psychiatrist contributes formulation, treatment of coexisting mental-health barriers, communication and advocacy.

Collaboration works best when communication is purposeful. With appropriate consent, a concise school note should state the relevant functional concerns, strengths, suggested adaptations and a request for feedback. It should not disclose more clinical detail than the educational purpose requires. Families need realistic discussion of what the school can implement and what must be reinforced at home. They also need protection from blame. Home practice can consolidate a skill, but it should not convert every evening into a second school day or a conflict around unfinished work.

Agree on one shared priority rather than giving each adult a separate agenda. Use a common language for the target behaviour or skill so that feedback is coherent. Review barriers to implementation before concluding that the child has "not responded".

Where disagreement arises, return to the child's educational participation and dignity. Families may fear stigma; schools may fear that requested changes are unmanageable; the child may refuse support that marks them as different. The psychiatrist can hold these concerns without promising an outcome that no single professional controls. Advocacy is strongest when it is concrete, respectful and grounded in what the child needs to learn and participate now.

22.6 Indian educational rights and the psychiatrist's advocacy role

IN INDIA

The Right of Children to Free and Compulsory Education Act provides the general statutory foundation: children aged **six to fourteen years** have a right to free and compulsory education in a **neighbourhood school**. The Rights of Persons with Disabilities Act adds a disability-specific right: a child with **benchmark disability**, aged **six to eighteen years**, has a right to free education in a neighbourhood or special school of choice.

For the psychiatrist, these provisions change the tone of the consultation. Education is not a discretionary favour to be requested when a child is easy to accommodate. It is a right within a statutory framework. The clinician should explain the practical relevance of this right, document educational needs clearly, and direct the family toward an informed discussion with the school and appropriate educational services. The doctor should not make unsupported promises about admission, resources or the exact form of provision, because these require local implementation and educational decision-making.

The disability statute also requires a periodic **survey of school-going children** to identify children with disabilities, determine their **special needs** and consider whether those needs are being met. This is to occur every **five years**. It matters clinically because identification should lead to a question about support, not merely to the production of a certificate.

Access	Choice	Need
EDUCATIONAL RIGHT	SETTING MATTERS	SUPPORT MUST FOLLOW

The educational prescription is complete only when it names the barrier, the support, the responsible partner and the route for review.

23 · Early intervention and stimulation programmes

Why it matters clinically. Early intervention improves participation and developmental opportunities before difficulties entrench. Stimulation programmes are its practical means: they help caregivers and professionals create meaningful opportunities for communication, movement, play, self-care and social engagement. The psychiatrist coordinates support.

The central question is whether the child can use emerging abilities in relationships, routines and settings that matter to the family. A programme begins with strengths, interests, health, sensory and motor needs, communication style, caregiving environment, opportunities to practise and

barriers to participation. This prevents generic advice when the obstacle is distress, family strain or an unmet physical need.

START	SHARED	REPEATED	REVIEW
WITH DAILY LIFE	FAMILY GOALS	MEANINGFUL PRACTICE	PARTICIPATION

23.1 Scope and therapeutic rationale

Early intervention is a coordinated developmental and family-centred response offered when a child has developmental vulnerability, delay, disability, or a context that threatens opportunities to learn. **Developmental stimulation** refers to intentionally enriching the child's ordinary experiences so that attention, interaction, exploration and practice are more likely to occur. These are related but not identical ideas. The former is a service approach that joins assessment, goal-setting, support and review; the latter is a set of everyday therapeutic opportunities within that approach.

Its rationale is developmental rather than diagnostic. Early experience shapes how a child learns to attend, anticipate, communicate and act on the environment. When an adult notices the child's signals, responds contingently, simplifies a task without stripping it of meaning, and repeats it within an enjoyable routine, the child has a clearer opportunity to connect action with consequence. The aim is not accelerated performance for its own sake. It is growing competence and agency in activities that the child and family actually need.

This distinction has practical consequences. A child may have a label yet need a plan centred on shared attention and communication; another may have no settled label but need help with play, mobility or caregiver interaction. Diagnostic clarification remains important, but intervention need not wait passively when current developmental needs are clear and support is safe.

RULE **Build intervention around participation in daily life, not around a list of isolated developmental tasks.** A skill becomes clinically useful only when the child can access it with real people, in ordinary routines and across relevant settings.

23.2 From concern to an individualised plan

A useful plan converts a broad concern into a shared working formulation. Begin by asking what is hard for the child and family at present, what is already going well, and what change would make the next period easier or more meaningful. Observe the child in interaction when possible. The child's initiative, affect, regulation, response to adult support and preferred activities often tell the clinician more about a workable starting point than a catalogue of deficits.

Functional goals are concrete descriptions of participation rather than abstract targets. They should be recognisable to the caregiver, relevant to the child's routine and capable of being observed without a specialised test. A goal about joining a mealtime exchange, tolerating a transition with support, seeking help during play, or participating in a self-care step is more useful than a vague instruction to improve development. The clinician should ask what the family will notice when the goal is becoming easier and what support will make that change possible.

- Identify a meaningful routine or activity in which participation is currently limited.

- Describe the child's present way of engaging, including strengths and successful conditions.
- Agree on an achievable next step and the adult response that will support it.
- Decide how the family and team will recognise progress, difficulty or an unintended burden.

The plan should specify who will do what, where opportunities will occur and how responsibilities will be coordinated. It also exposes a familiar service problem: a recommendation can sound clinically elegant while requiring time, transport, money, equipment or adult availability that the family does not have. The correct response is adaptation, not blame. A smaller intervention woven into real routines is often more therapeutic than a plan that survives only on paper.

GOOD TO REMEMBER

When a caregiver says, “We cannot do all this,” treat that statement as assessment data. It may reveal exhaustion, competing care demands, poverty, grief, misunderstanding, family conflict or a plan that has not yet become usable. Simplifying the plan may be the intervention that restores continuity.

23.3 The active ingredients of stimulation

Stimulation is not the accumulation of toys, worksheets or appointments. Its active ingredients are attunement, repetition, graded challenge, feedback, enjoyment and transfer into daily life. Adults first follow the child's interests and signals. They then create a small, manageable demand, wait for the child's response, and adjust assistance so that the child has a genuine role in success. This is **scaffolding**: support that makes participation possible without permanently doing the task for the child.

Play is particularly valuable because it permits repetition without making the child feel tested. Shared play can support turn-taking, symbolic communication, motor planning, frustration tolerance and relationship-building, but it should be guided by the child's developmental level and sensory profile. The detailed principles and techniques of play therapy belong in the play therapy section. In a stimulation programme, play is usually a vehicle for practice and connection rather than a separate psychotherapy.

Communication support is embedded in ordinary encounters. Adults can make language and gestures easier to understand, allow time for a response, offer meaningful choices, and respond to attempts to communicate rather than waiting for polished performance. Motor and self-care opportunities work best when the activity has an immediate purpose. Feeding, dressing and moving through the home can become therapeutic contexts when adapted thoughtfully.

THERAPEUTIC ELEMENT	CLINICAL QUESTION	PRACTICAL IMPLICATION
Child interest	What draws the child into interaction?	Use preferred people, objects and activities as the entry point.
Adult response	How does the caregiver recognise and answer the child's signal?	Model waiting, noticing and responding in a way the child can use.
Task demand	What makes participation fail or become distressing?	Reduce unnecessary complexity and increase challenge gradually.
Routine	Where can practice happen naturally?	Attach the activity to a familiar part of the family's day.
Generalisation	Can the child use the emerging skill with other people and places?	Plan transfer deliberately instead of assuming it will occur.

The mechanism is relational. A programme works through adults as well as through the child. Caregivers gain confidence when they can read the child's cues and see that their response changes the interaction. That confidence can reduce helplessness and make ordinary family routines more predictable. Conversely, instructions that imply the caregiver is solely responsible for developmental outcome can intensify guilt and undermine engagement. The clinician should explicitly distinguish responsibility for providing opportunities from responsibility for producing a particular developmental result.

23.4 Caregiver partnership and family work

Caregiver coaching is the process of helping a caregiver observe, try, reflect on and adapt an interaction with the child. It is not simply teaching the caregiver to reproduce professional techniques. The caregiver knows the child's habits, comforts, fears and available routines; the professional contributes developmental reasoning and an outside perspective. The partnership is strongest when these forms of knowledge are treated as complementary.

Use demonstration sparingly and then return the activity to the caregiver. Ask what felt easy, what the child seemed to enjoy, where the interaction broke down, and what change might make the next attempt more feasible. This reflective loop converts advice into learning. It also avoids an unhelpful service pattern in which the child appears to perform with a therapist but the family leaves without a method that can be used between visits.

Family intervention may be needed when parental mental health difficulties, conflict, stigma, bereavement, substance use, violence, unsafe housing or competing caregiving burdens limit the child's opportunities. These circumstances are not “non-compliance.” They are part of the formulation. The family therapy and family intervention section addresses therapeutic approaches to relational difficulties in greater detail. Here, the task is to ensure that the developmental plan does not ignore the conditions that make implementation possible or impossible.

IN INDIA

Early support often requires coordination across home, clinic, educational settings, rehabilitation providers and local child-development services. The psychiatrist should help the family navigate these interfaces without assuming that every locality has the same professional availability. A written, plain-language plan can reduce fragmentation when families move between public, private and voluntary-sector care.

23.5 Interdisciplinary and educational coordination

Early intervention is rarely delivered by psychiatry alone. Depending on the child's formulation, collaboration may be needed with paediatrics, rehabilitation professionals, speech and language support, psychology, nursing, social work and educators. The psychiatrist's role is to hold the clinical formulation together, address co-occurring emotional or behavioural barriers, clarify priorities with the family and prevent parallel services from becoming competing services.

Educational support should be considered early whenever learning or participation is affected. The special education and remedial intervention section addresses educational planning in detail. Within an early intervention plan, the essential question is whether the environment can be adjusted so that the child can participate, communicate needs and experience success. A recommendation for a setting is not enough. The team should communicate the child's helpful supports, likely triggers for disengagement and practical ways to preserve dignity.

Generalisation is the transfer of a developing ability from the place in which it was learned to other people, materials and settings. It is a clinical outcome, not an optional extra. A child who can perform only under highly structured professional prompting may still be unable to participate in family life or education. Plans therefore need planned overlap between home, therapy and school, with shared language and expectations where feasible.

MNEMONIC

START

Share goals with the family, **T**ailor activity to the child, **A**rrange practice in routines, **R**eview participation and burden, and **T**ransfer gains across settings. It is a compact way to remember that stimulation is a coordinated process rather than a collection of activities.

23.6 Monitoring change and revising the plan

Review should ask whether participation is changing, not simply whether the family has completed prescribed exercises. Look for the child's initiative, comfort, capacity to recover from frustration, use of support and ability to engage with familiar people. Ask caregivers what has become easier, what remains hard, what has changed unexpectedly and what the intervention costs them in effort or conflict. A plan that expands a child's skills while exhausting the caregiving system needs revision.

When progress is limited, return to the formulation. The task may exceed the child's current readiness; the goal may lack relevance; the setting may be too distracting or demanding; the adult

prompt may be poorly timed; health, sensory, sleep or emotional difficulties may be interfering; or the family may need a different kind of support. Escalating intensity without understanding the mismatch is rarely good clinical practice. A respectful review protects the family from feeling judged and protects the team from mistaking activity for effectiveness.

TRAP **Do not equate a busy intervention schedule with an effective programme.** Candidates often describe multiple therapies but omit the child-specific goal, caregiver role, setting and review process. In practice, the same omission produces fragmented care and makes it impossible to know what should be continued, changed or stopped.

PITFALL

Do not make a caregiver demonstration into a performance test. Correcting every imperfect response can silence the very adult whose consistency the programme depends on. Preserve curiosity, identify the next useful adjustment and acknowledge what the caregiver already does well.

23.7 Boundaries, referral and ethical stance

Early intervention does not replace diagnostic assessment, medical care, safeguarding, education planning or specialist treatment when these are needed. It brings their developmental implications into the child's everyday world. If a child has acute medical concerns, sensory difficulties, nutritional problems, exposure to violence, severe caregiver distress or a marked change in functioning, address the relevant pathway rather than persisting with stimulation alone. Safeguarding concerns require the protection response described in the child protection sections.

The psychiatrist should avoid deterministic language. Families may hear a developmental formulation as a verdict about the child's future or their parenting. Explain uncertainty honestly, describe the present purpose of intervention, and invite the family to identify what a good outcome would look like in their circumstances. Respect for culture and family priorities does not mean accepting harmful practices or excluding the child from opportunity. It means designing support with the family rather than imposing a professional script.

Early intervention succeeds when a child gains meaningful participation through repeated, enjoyable opportunities that caregivers can realistically sustain.

Epidemiology, services and national context

24 · Epidemiology of child psychiatric disorders in India

Why this matters clinically. Epidemiology in child psychiatry is not a decorative prevalence quotation. It determines how confidently a clinician can describe the size and distribution of need, whether a local service claim is defensible, and whether a research finding can be carried into an individual formulation. In India, the central skill is often not recalling a headline

percentage; it is recognising the population to which that percentage does, and does not, apply. This distinction is especially important when a family, school, administrator, or trainee asks for "the Indian figure" for child mental disorder.

For the present purpose, **epidemiology** means the disciplined description of mental health phenomena in a defined population. It asks who was sampled, how cases were identified, the period to which findings refer, and whether the denominator matches the question being asked. It does not establish the diagnosis of the child in front of the clinician, nor does it replace a developmental and multi-informant assessment. Those clinical tasks are addressed in the assessment sections of this chapter and the childhood disorders themselves are covered in *the Child behavioural, emotional and other disorders notes*.

24.1 What an Indian child-psychiatry prevalence statement must mean

A prevalence statement is only as useful as its case definition and sampling frame. "Mental morbidity" may represent a diagnostic interview threshold, a symptom screen, a clinician's judgement, a service contact, or an administrative record. These are related but non-interchangeable constructs. A symptom measure can be useful for detecting need or planning further assessment; it cannot silently be converted into the prevalence of a psychiatric disorder. Likewise, clinic attendance tells us about treated or help-seeking morbidity, not the frequency of disorder in children who are outside services.

Case definition is therefore a priority interpretive question. It should make clear whether the estimate refers to current mental morbidity, symptoms, impairment, a particular diagnostic grouping, or a mixture of these. In developmental psychiatry, impairment and context matter greatly: behaviour that prompts concern in a classroom may have a different meaning after considering developmental level, language, family stress, neurodevelopmental profile, and the informant's opportunity to observe the child. A defensible epidemiological estimate preserves the method used to decide who counted as a case.

The next question is the **denominator**. A denominator is not merely a total at the foot of a table. It identifies the population from which the estimate was derived. Household samples, school samples, clinic samples, and selected community groups answer different questions because the children available for recruitment, and the pathways by which concerns become visible, differ. A school-based study may be highly valuable for school planning while excluding children whose educational participation is interrupted. A clinic sample may accurately describe service demand while being shaped by access, referral practices, stigma, affordability, and local specialist availability.

- Ask whether the source sampled the population named in the question.
- Identify how a case was defined and whether impairment was part of that definition.
- Check the age group before applying a finding to "children".
- Separate a local estimate from an all-India estimate.

RULE **Never detach a prevalence figure from its population, age group, case definition, and sampling frame.** A number may be accurate within its study yet misleading when presented as a national child estimate. In an answer, state the scope before interpreting the figure; this shows epidemiological judgement rather than rote recall.

24.2 What the NMHS adolescent finding can support

The National Mental Health Survey, commonly called **NMHS**, is the key national survey reference that candidates are likely to encounter. Its adolescent module reported current mental morbidity of **7.3%** among adolescents aged **13-17 years**. The estimate used a structured diagnostic approach. The report does not specify which instrument the adolescent module used, so this note names none. It is reasonable to cite this as an adolescent-stratum finding when the wording remains equally precise about its limits.

Its limits are not footnotes. The adolescent component was a feasibility sub-sample confined to **four** of the survey states, rather than a nationally representative adolescent survey. The wider survey covered **12** states, but that does not make the adolescent module a national child survey. The exact adolescent-stratum denominator is not provided in the cited report, so a clinician should not manufacture precision around the estimate or imply that it describes every Indian region.

7.3%	13-17 years	four	not established
CURRENT ADOLESCENT MENTAL MORBIDITY	AGE STRATUM	STATES IN FEASIBILITY SAMPLE	ALL-INDIA CHILD FIGURE

IN INDIA

Use the NMHS result as a carefully bounded adolescent finding, not as a shortcut for "Indian child prevalence." This is particularly relevant in local planning discussions: a national survey label may create unwarranted confidence if the reader does not notice which participants contributed to the adolescent result.

External validity is the question of how far a study's finding can travel beyond those studied. Here, the result travels to the adolescent feasibility stratum defined by the survey methodology. It does not automatically travel to younger children, every state, all school settings, or every clinical service context. This is not a criticism of the survey. It is the ordinary discipline of applying evidence to the population actually represented.

24.3 The honest national gap for children

No established all-India psychiatric prevalence figure can be quoted for children under **13 years**. That gap is substantive, not a wording problem. The available NMHS adolescent stratum begins later, so it cannot be extended downwards by intuition, by averaging unlike studies, or by treating "child and adolescent" as a single epidemiological population. The correct answer is that the all-India child prevalence is **not established**, while an adolescent feasibility-subsample estimate is available with the limitations already described.

This phrasing protects against a common but consequential error: welding a national-looking range from studies with different ages, settings, instruments, informants, and thresholds. Such a range looks balanced because it appears to acknowledge variation, but it does not acquire national validity by spanning several local results. It can also conceal the distinction between symptom burden, probable disorder, diagnosed disorder, and service use. Where evidence is heterogeneous, a careful narrative description of the evidence base is stronger than an invented composite.

TRAP **Do not quote the adolescent NMHS percentage as the prevalence of child psychiatric disorders in India.** The age band and sampling design limit the claim. A polished-looking number without its denominator is a category error, not a concise answer.

PITFALL

Do not substitute a foreign data platform for Indian prevalence evidence merely because it is easy to search or presents polished charts. A source that is **US-only** cannot supply an India estimate. The practical response is to label the Indian evidence gap, not to import a figure.

24.4 Geographic inference and the Karnataka limitation

National language can obscure geographic limits. In the NMHS state list, **Karnataka** was not included. Therefore, the survey cannot be cited as a Karnataka child or adolescent prevalence source. This matters for clinicians and teachers working in the state because a national report is often assumed to settle a local question. It may offer useful context about survey methods and the broader Indian evidence base, but it does not replace a population estimate from the population of interest.

Local relevance should be reasoned rather than presumed. A finding is more likely to inform local planning when the population, setting, language context, social conditions, pathways to care, and service availability resemble the intended setting. Conversely, a difference in any of these can alter observed prevalence or, more commonly, the probability that distress is noticed and reaches care. The point is not that a study from elsewhere is useless. It is that transportability must be argued, and uncertainty stated, rather than hidden behind a national title.

QUESTION BEFORE QUOTING A FIGURE	WHAT MUST BE CHECKED	CONSEQUENCE IF THE ANSWER IS UNCLEAR
Who was sampled?	Household, school, clinic, or other defined population	Do not relabel the result as community prevalence.
What ages were included?	Whether the child group matches the clinical question	Do not generalise an adolescent estimate to younger children.
How was morbidity identified?	Diagnostic interview, symptom measure, or service record	Name the construct rather than calling all results "disorder".
Where was the study done?	Geographic coverage and whether the locality was sampled	Describe it as contextual evidence, not local proof.
What is the denominator?	Whether the relevant stratum is explicitly reported	Avoid false precision and unsupported comparisons.

Transportability is the clinical version of this judgement: whether evidence collected in one context is likely to be informative in another. It is especially useful when discussing service needs. Epidemiology can guide the scale and direction of planning, but it should not be used to predict a particular child's diagnosis, family trajectory, or treatment response. Individual care remains anchored in direct assessment and formulation.

24.5 Why estimates vary without being mutually contradictory

Variation between studies does not by itself prove that a study is wrong. In child mental health, observed differences may arise from the age composition of the sample, whether parents, teachers, and children contribute information, the threshold selected for a case, the privacy of interviews, local explanatory models, and the route by which participants are recruited. These factors affect ascertainment as well as the underlying distribution of difficulties. The reader's task is to distinguish a real epidemiological difference from a difference created by study design.

Ascertainment refers to the process by which possible cases are noticed, assessed, and counted. It is vulnerable to both under-recognition and over-interpretation. Children with internalising difficulties may not be noticed in the same way as children with disruptive behaviour; conversely, school or family concern may be shaped by expectations that are not themselves diagnostic. Such observations are clinically important, but they are not grounds for supplying a prevalence figure where no appropriately sampled figure exists.

Keep symptom detection separate from diagnostic classification; functional concern separate from the prevalence of a named disorder; service utilisation separate from population burden; and an evidence gap separate from an assertion that no affected children exist. These distinctions make the epidemiological description clinically usable without inflating what the evidence can establish.

For examination writing, this reasoning earns marks because it explains why figures cannot be compared casually. For service work, it prevents a more serious problem: allocating scarce attention solely to the forms of distress that are easiest to count. Epidemiology should widen clinical curiosity, not reduce a child to a survey category.

GOOD TO REMEMBER

When asked for a prevalence figure during a case discussion, state what the available estimate actually measures, then state the limit on applying it to the child population in question. This is more clinically useful than giving an unsupported number with apparent confidence.

24.6 Using epidemiology without misusing it

At bedside level, epidemiology supports anticipation and advocacy. It reminds the psychiatrist that childhood mental health need exists beyond specialist clinics, that detection pathways are selective, and that absence of a local population estimate is not evidence of absence of clinical need. It can help frame a request for school linkage, developmental supports, family intervention, or service strengthening. It should never become a diagnostic shortcut, a reason to dismiss symptoms that fall outside a survey category, or a substitute for listening to the child and caregivers.

At service level, use epidemiological language proportionately. Describe the need as recognised but incompletely quantified when the population evidence is incomplete. Specify whether a proposed programme is responding to clinic demand, observed school concerns, or population surveillance. These categories can inform each other, yet they are not interchangeable. School mental health programmes and life-skills education are addressed separately in this chapter; their justification should not depend on pretending that a single national prevalence statistic answers every planning question.

In India, cite the NMHS adolescent result only with its age and sampling limits; for younger children, state plainly that an all-India psychiatric prevalence figure is not established.

The mature answer is therefore neither nihilistic nor numerically performative. It is evidence-literate: it acknowledges the available adolescent signal, protects the boundary around it, identifies the missing child and local estimates, and explains why those boundaries matter for clinical interpretation. That stance is not evasive. It is the ethical use of epidemiology in child psychiatry.

25 · School mental health programmes and life-skills education

Why this matters clinically. A child's mental health is lived in ordinary settings, not only in the clinic. School is where learning demands, peer relationships, exclusion, bullying, family expectations and emerging autonomy become visible. **School mental health** therefore means more than placing counselling in a school. It is a way of making the school safer, more emotionally literate and more able to notice when a pupil needs support beyond the classroom. For the psychiatrist, it is a service question: what can be strengthened in the child's daily environment, what needs clinical assessment, and how can the two remain connected without turning teachers into diagnosticians?

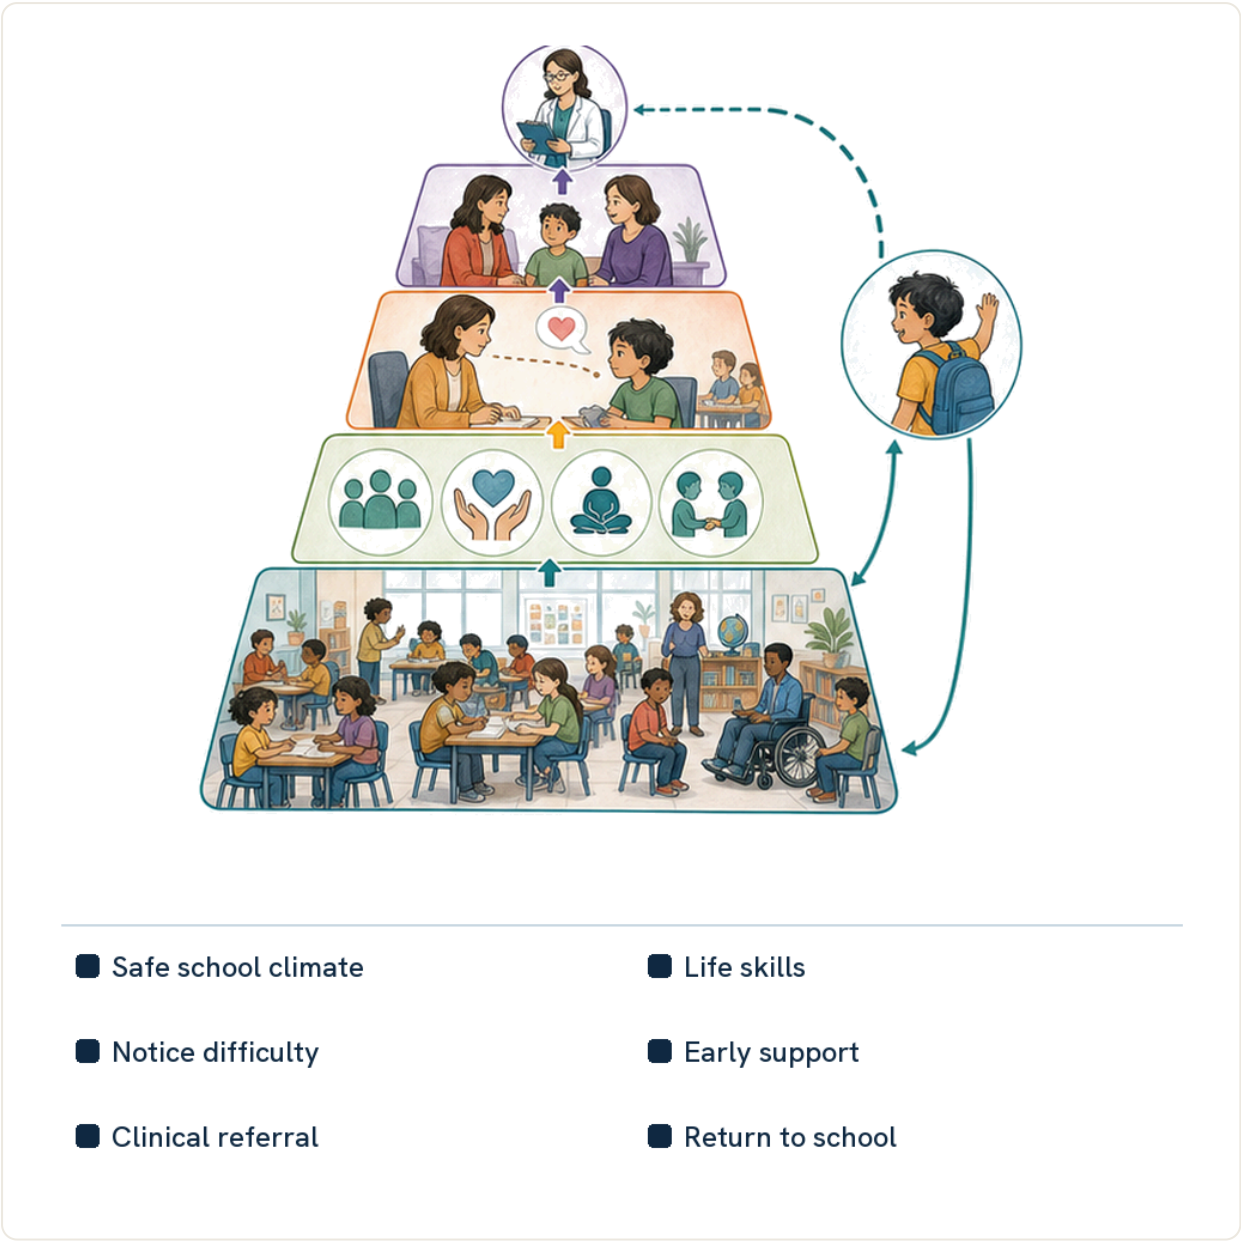

Fig 24.11 School mental-health programmes move from universal promotion and life-skills education through recognition and early support to a linked clinical referral pathway. Schools notice and support; they do not become diagnostic clinics.

The examination value of this area lies in making those distinctions clearly. A well-written answer moves from health promotion through life-skills teaching to referral pathways, then locates Indian programmes without confusing one platform with another. It does not re-teach childhood disorders, behavioural treatment or the formal child assessment. Those require their own clinical formulations and are addressed in the Child behavioural, emotional and other disorders notes; the general assessment framework is addressed elsewhere in this chapter.

25.1 What a school mental health programme is for

A school mental health programme is a planned response to the social and emotional conditions in which pupils learn. Its aim is not to find a psychiatric label for every difficulty. Its practical task is to improve the everyday capacities that help children and adolescents negotiate demands, relationships, conflict, disappointment and help-seeking. It also gives adults in the school a language for responding thoughtfully rather than with humiliation, exclusion or an automatic demand for medical certification.

Good programmes work at the level of the school climate as well as the individual pupil. A child who is quiet, irritable, distracted or repeatedly absent may be signalling distress, but none of those observations is itself a diagnosis. The school can offer predictable routines, respectful communication, opportunities for participation and an adult who takes concerns seriously. Where difficulties are persistent, impairing, risky or beyond the school's competence, the school's role is to share observations with caregivers and facilitate an appropriate referral. Diagnostic assessment remains a clinical responsibility, undertaken with developmental, family and multi-informant context.

RULE **Teach competence and create a route to care; do not convert the classroom into a diagnostic clinic.** A school can reduce barriers to disclosure and support early help-seeking, but it should neither assign diagnoses nor manage serious risk in isolation.

The distinction protects both child and school. If every academic or behavioural difficulty is medicalised, ordinary adversity is treated as pathology and the pupil can acquire a stigmatising identity. If every difficulty is dismissed as indiscipline, a child with real distress may be shamed and left unsupported. The useful middle position is curiosity: describe what has changed, ask what context might explain it, listen to the child and caregiver, and decide whether ordinary school support, a planned conversation or clinical referral is needed.

Why the setting changes the intervention. Therapy often asks a child to practise a new response between sessions. School is one of the places where that practice either becomes possible or is repeatedly undone. A programme that normalises respectful peer interaction, problem solving and asking for help can make clinical gains easier to use in real life. Conversely, a punitive or mocking environment can defeat carefully planned treatment. Liaison is therefore not an optional add-on to child psychiatry; it is part of making an intervention usable in the child's world.

25.2 Life-skills education: the educational core

Life-skills education is skills-based teaching intended to build **psychosocial competence**. It is not a lecture on good behaviour and not a covert diagnostic screen. Its central premise is that children benefit when they can recognise a situation, consider options, regulate an immediate response, communicate their needs and learn from the result. The emphasis is on rehearsal and reflection, so that an idea becomes a usable action rather than a slogan remembered after an assembly.

The WHO core set is most useful as an organising language for curriculum and teacher preparation. It connects thinking, relating and emotional self-management without implying that each domain is a separate subject or that the child must perform a particular personality. The accompanying table groups the skills for teaching purposes while retaining their practical meaning.

CORE CAPABILITY	WHAT IT LOOKS LIKE IN A SCHOOL ACTIVITY	CLINICAL RELEVANCE
Decision making and problem solving	Pausing to define a difficulty, generate options and consider likely consequences.	Supports a move from impulsive reaction to deliberate choice.
Creative thinking and critical thinking	Considering more than one explanation, questioning assumptions and imagining alternatives.	Helps pupils examine peer pressure, rumours and self-defeating conclusions.
Effective communication and interpersonal relationship skills	Listening, expressing a request, disagreeing without attack and repairing a misunderstanding.	Makes interpersonal stress discussable before it escalates.
Self-awareness and empathy	Noticing one's own feelings and perspective while attempting to understand another person's experience.	Supports reflection, peer inclusion and less hostile attribution.
Coping with emotions and coping with stress	Naming an emotional state, identifying a trigger, using a safe coping response and seeking support when needed.	Creates a common vocabulary for distress without presuming illness.

These skills are learned best through participation. A teacher may use a brief vignette, a role-play, a classroom dilemma, a guided discussion, a drawing task or a reflection on a familiar conflict. The educational sequence matters: introduce a concrete problem, allow pupils to generate responses, practise a response in a safe setting, receive feedback, and return to where that skill may be useful outside the activity. A child should not be compelled to disclose private experiences in front of peers in order to demonstrate learning.

GOOD TO REMEMBER

When a child is already in treatment, ask what skill is being practised and where it fails in the school day. A small, specific environmental adjustment - a predictable check-in, permission to step aside briefly, or a named adult for help-seeking - may make therapy more transferable without asking the school to provide therapy.

Life-skills teaching should remain developmentally intelligible. Abstract language about resilience or emotional intelligence is easily repeated without being understood. Activities should use situations pupils actually recognise, offer alternatives rather than moralising, and permit different ways of participating. The desired outcome is not silent compliance. It is a child who can think, communicate and seek help with increasing agency while respecting the safety and dignity of others.

25.3 From a session to a school culture

A programme fails when it treats a single teaching session as a completed intervention. The content needs a place in ordinary school life: teachers need to model respectful disagreement, classroom rules must not contradict the message of empathy, and pupils need safe opportunities to use the skills. Repetition is valuable when it is practice in varied situations, not when the same

message is simply recited again. Follow-up discussion allows children to identify what was difficult, what helped and what support would make the next attempt more realistic.

- Choose situations that are familiar enough for pupils to engage, but do not require public disclosure of personal adversity.
- Use active methods that let pupils try language, choices and coping responses rather than only hear about them.
- Build in a private route for a pupil to seek help after a session, because a group activity may surface an individual concern.
- Review whether the school's disciplinary and peer practices reinforce or undermine the values being taught.

Teachers are central because they are the adults who can make a classroom emotionally predictable, but they must be supported rather than burdened with a vague instruction to "handle mental health". Training should clarify the limits of the teacher role, the route for consultation, how to speak with caregivers, and when a concern needs urgent escalation. It should also address the teacher's own anxiety: staff may avoid a distressed pupil because they fear saying the wrong thing. A calm, non-judgemental first conversation and a known referral route are safer than avoidance.

PITFALL

Do not mistake a school programme for a substitute for clinical care. A school may support attendance, inclusion and help-seeking, but it cannot safely absorb a complex presentation, sustained functional deterioration or a concern about immediate safety merely because a life-skills session exists.

Peer involvement can be constructive when it expands inclusion and reduces isolation, but peers should never be made responsible for surveillance, counselling or secrecy. A child may prefer a trusted friend to accompany them in seeking an adult, yet the adult remains responsible for deciding what support is needed. This protects friendship from becoming an unacknowledged clinical role and keeps the burden of safeguarding with the institution and appropriate services.

25.4 Boundaries, confidentiality and referral

School work frequently raises a tension between privacy and collaboration. The child should know, in language they can understand, who will be told about a concern and why. Information shared with a school should be limited to what is necessary for the agreed support plan. A psychiatrist need not disclose a diagnostic formulation or detailed family history for a teacher to understand the practical accommodations that may help. Equally, a teacher should not promise secrecy when information suggests that the child may be unsafe or needs protection.

Referral communication is strongest when it is descriptive. It records observable changes, relevant school context, duration in ordinary language and the supports already tried, rather than attaching a label. The clinician can then integrate that account with the child's history, caregiver

perspective and direct assessment. This approach also reduces the common conflict in which a family feels blamed by the school while staff feel dismissed by the family. Both are usually reporting different parts of the same child's context.

TRAP **Do not equate a teacher's observation with a psychiatric diagnosis.** Teachers provide indispensable ecological information, but an observation gains clinical meaning only when it is integrated with developmental, family and direct assessment. The general assessment framework is addressed elsewhere in this chapter.

Where the concern indicates abuse, serious violence, self-harm, sexual harm, or immediate danger, the matter leaves the ordinary school support pathway. The clinician and institution must follow the relevant protection and emergency processes rather than wait for further classroom observation. The statutory duties and child-protection response are addressed in the chapter sections on POCSO, juvenile justice and management of child abuse; a school programme should have a clear pathway to those systems, not improvise one in a crisis.

25.5 India: DMHP school outreach

IN INDIA

Under the District Mental Health Programme, targeted outreach includes life-skills education and counselling in schools. The programme model specifies **100 teachers** as master trainers from each block, with a block described as having **25-30 schools**. This makes the teacher a capacity-building link, not a replacement for a mental-health professional.

The DMHP formulation is important because it places school work within public mental-health outreach rather than treating it as an isolated educational experiment. Its strength is reach: a trained teacher can carry a consistent set of activities and can identify when a pupil needs a conversation or referral. Its limitation is equally important: the quality of implementation depends on supervision, protected time, turnover of trained staff, links with the district team and the school's willingness to use a non-stigmatising approach.

For a psychiatrist working with a district or medical college service, the useful contribution is not to deliver every session personally. It is to help build a workable system: orient staff to what school support can and cannot do, advise on referral criteria, receive clinical referrals appropriately, and use feedback from schools to improve the pathway. Consultation should focus on function and safety rather than asking teachers to master psychiatric terminology. A brief, respectful response to a referred child also builds trust in the pathway and makes future help-seeking more likely.

- Clarify who in the school receives a concern and who communicates with caregivers.
- Ensure that referral does not become a disciplinary disposal of a difficult pupil.
- Agree how urgent concerns will reach a responsible adult and appropriate service without delay.
- Feed back practical school recommendations while preserving the child's privacy.

25.6 RKSK and adolescent-facing care

Rashtriya Kishor Swasthya Karyakram was launched on **7 January 2014**. It is framed to reach **253 million adolescents aged 10-19 years, including those in and out of school, across gender, residence and marital status**. This breadth matters when school mental health is discussed: school delivery is valuable, but it cannot be the only route to adolescent support.

RKSK places mental health alongside sexual and reproductive health, nutrition, substance misuse, injuries and violence including gender-based violence, and non-communicable diseases. Its Adolescent Friendly Health Clinics provide a clinical and counselling interface for these concerns. The domains should be understood as connected in the young person's lived experience. A school discussion about coping, relationships or violence may open a question that needs an adolescent-friendly health service rather than a further classroom activity.

The psychiatrist's role is to understand the interface, not to collapse it. School-based promotion can improve recognition and reduce hesitation about seeking help. Adolescent-friendly services can offer an accessible point for counselling and health concerns. Specialist mental-health care is indicated when the presentation requires diagnostic assessment, risk management or treatment beyond that setting. Clear hand-offs protect the young person from being sent repeatedly between systems with no one accepting responsibility.

25.7 The School Health and Wellness Ambassador model

The Ayushman Bharat School Health and Wellness Programme uses a teacher-led health-promotion model. The designated **Health and Wellness Ambassadors** are two teachers per school, preferably one male and one female where possible. The programme describes a health-promotion session of one hour each week. These details are useful as an examination anchor, but the clinical interpretation remains more important: the model creates a named, trained point of contact within the school rather than leaving health promotion to individual enthusiasm.

10	100	253 million	2
WHO CORE LIFE SKILLS	DMHP TEACHER MASTER TRAINERS PER BLOCK	ADOLESCENTS TARGETED BY RKSK	TEACHERS DESIGNATED PER SCHOOL

Named ambassadors can make it easier for pupils and families to know whom to approach, and for a school to sustain health conversations over time. Yet designation alone does not guarantee safety or quality. The programme needs administrative support, a private and respectful route for individual concerns, a clear escalation pathway, and collaboration with local health services. The teacher is best viewed as a facilitator of health promotion and access, not as a counsellor for every personal problem.

> School mental health succeeds when life-skills teaching, a supportive school climate and a clear route to clinical or protection services work as one system.

26 · Rashtriya Bal Swasthya Karyakram (RBSK) and the 4Ds

Why it matters clinically. A child psychiatrist sees only a fraction of the children whose development, behaviour, communication, hearing, vision, nutrition, chronic illness, or congenital health needs may affect mental health. The service question is therefore not merely whether a child meets criteria for a psychiatric disorder. It is whether the child has been noticed early, whether the family has understood the concern, and whether there is a workable route from a screening finding to assessment, intervention and review. **Rashtriya Bal Swasthya Karyakram (RBSK)** is an Indian child-health platform built around early identification and linkage to care.

For the examination candidate, RBSK is best understood as a service architecture rather than as a list of diagnoses. It supplies a common public-health language for a heterogeneous set of childhood health concerns and creates a route into district-level intervention. Its relevance to psychiatry is especially clear when developmental, sensory, medical and family factors coexist. A referral generated by the platform is a clinical starting point: it should lead to formulation and coordinated care, not to premature diagnostic labelling.

26.1 The 4Ds: a service language for early identification

The organising frame is the **4Ds**. It brings together defects at birth, deficiencies, diseases, and developmental delays including disabilities. This is deliberately broader than psychiatric nosology. A public programme must detect concerns that are visible to families, teachers, frontline workers and health staff before specialist diagnosis is possible. The framework also prevents the false separation of physical and developmental health: a concern that begins in one domain may change a child's learning, participation, sleep, communication, behaviour or family stress in another.

4Ds	birth to 18 years	up to 6 years	30
ORGANISING FRAMEWORK	SCREENING SCOPE	PRIMARY DEIC FOCUS	CONDITIONS, ORIGINAL SCHEME

Do not read the categories as separate clinical silos. They are a prompt to ask what has been found, what may be contributing to it, what the child can currently do, and what service can act next. For example, a child with poor classroom participation may need medical or sensory clarification, developmental assessment, educational support and family guidance in parallel. Psychiatry contributes a formulation of emotional and behavioural consequences, caregiver burden, adherence barriers and comorbid symptoms. It does not convert a screening category into a diagnosis by itself.

RULE **The 4Ds are a route into care, not a psychiatric diagnostic system.** Use the framework to widen the clinical lens and to organise referral, then complete the assessment needed for the individual child.

MNEMONIC

Birth, Body, Biochemistry, Behaviour and development

Use this bedside prompt to remember that the programme categories include birth defects, diseases, deficiencies, and developmental delay including disability. The added behavioural wording is a clinical reminder, not an additional programme category: it asks the psychiatrist to consider the child's functioning and family response after the health concern has been identified.

The programme's screening and referral card, as issued under the original scheme, listed **30** core health conditions under this framework, and that remains the figure most examination answers expect. It is no longer the current list. The RBSK 2.0 operational guidelines set out a revised and longer table and publish no total at all, so the count is best taught as the classical figure with that caveat rather than as a settled number. The revision matters here for a second reason: the current table names behavioural and neurodevelopmental conditions explicitly, among them anxiety disorders, sleep disorders, attention-deficit hyperactivity disorder, autism spectrum disorder, specific learning disorders and global developmental delay. The practical lesson is not to memorise a card as though it were a diagnostic manual. Rather, recognise the card as a standardised handover. It records why the child was identified and helps the receiving service decide what must be clarified, what can be acted on locally, and where specialist input is needed. A useful referral note adds the child's functional difficulty, the informant's concern, prior care, family understanding and the immediate question for the next clinician.

26.2 From population contact to a clinically meaningful referral

The programme uses **Mobile Health Teams** for **community screening** in Anganwadis and Government schools. This matters because these are routine child-contact settings rather than specialist clinics. They can surface a concern in a family that has not sought mental-health care, or in a child whose difficulties have been normalised, attributed to temperament, or hidden by school absence. The initial service task is detection and communication, not a definitive mental-state examination.

In service terms, the pathway must preserve information as it moves. A vague referral such as “developmental problem” can leave the caregiver uncertain and the receiver unable to triage. A good handover states what was observed, the context in which it was observed, the functional consequence, any already-known health information, and what the referring worker has told the family. When a psychiatrist receives such a child, the referral concern should be checked against caregiver and child accounts before it is interpreted. This protects against both under-recognition and the equally damaging tendency to treat a screening label as settled fact.

STAGE IN THE PATHWAY	PRIMARY PURPOSE	PSYCHIATRIC CONTRIBUTION	COMMON ERROR TO AVOID
Child-contact setting	Notice a possible health or developmental concern	Recognise that distress or behaviour may signal unmet developmental, medical or family needs	Expecting a screening encounter to establish diagnosis
Referral communication	Transfer the reason for concern and the next step	Clarify what the family understands and what may impede attendance	Using a label without describing functional difficulty
Receiving service	Decide what assessment and intervention are needed	Place symptoms in developmental, family, educational and health context	Reducing the case to a narrow specialty
Care plan	Make responsibilities visible to the family and services	Integrate psychological, family and educational needs with other care	Giving advice without a named follow-up route
Review	Check whether the planned help was actually accessed and useful	Reassess function, burden and emerging mental-health needs	Equating referral completion with clinical benefit

The screening population extends from **birth to 18 years**. That breadth should shape a psychiatrist's service thinking. The referral question, the informant and the setting change across childhood and adolescence, even when the broad programme language remains the same. Avoid assuming that the same presentation, threshold for concern, or pathway will be appropriate across the entire age span. The programme gives a common entry point; clinical assessment remains developmentally anchored.

TRAP **Do not describe RBSK as a child psychiatry service.** It is a child-health screening and linkage platform whose categories may bring children with mental-health relevance to attention. The psychiatrist's role begins with collaborative clinical work after the concern has been identified.

26.3 DEIC as the district intervention and coordination hub

A **District Early Intervention Centre (DEIC)** is intended to provide **comprehensive management** under one roof. This phrase should be read functionally. It signals a hub that can receive children flagged through screening, direct them towards appropriate assessment or intervention, and maintain a referral link when the required service lies elsewhere. The value is coordination: the family should not be left to translate a screening observation into a sequence of disconnected consultations.

IN INDIA

For psychiatric practice, RBSK provides a public-system route for a child whose presenting concern crosses developmental, medical, sensory, educational and emotional boundaries. The useful clinical question is not whether the DEIC replaces specialist care. It is whether the centre can help assemble the next assessment, intervention and follow-up steps around a family who may otherwise move between services without a shared plan.

DEICs primarily serve children **up to 6 years of age**. This distinction is important. The broader RBSK screening platform reaches through adolescence, whereas the DEIC is particularly oriented to the early childhood window. In an answer, state the distinction plainly rather than collapsing all RBSK functions into the DEIC. In clinical work, it prompts an early check of whether a young child with a developmental or disability-related concern has an accessible intervention route, while older children may need linkage through the relevant services available locally.

Coordination is not a passive administrative act. It includes making the referral question intelligible, checking whether caregivers can reach the destination service, identifying whether several disciplines must be involved, and ensuring that a child is not lost because one part of the plan is delayed. Psychiatric input can be particularly useful when caregiver anxiety, stigma, conflict about the meaning of the child's difficulties, or behavioural distress threaten engagement. That work is supportive and collaborative. It should not pathologise an understandable family reaction to uncertainty.

> **GOOD TO REMEMBER**
>
> When a young child is referred after programme screening, ask the caregiver to show what the child can and cannot do in daily routines. This converts an administrative referral into a functional clinical question and makes it easier to coordinate advice across services without prematurely assigning a disorder label.

26.4 Why the early-intervention window is emphasised

The rationale for early action is developmental rather than merely administrative. The programme identifies **early intervention** from **birth to 6 years** as a particularly critical period for child development, especially when developmental delay is present. This does not imply that later intervention is futile. It means that delay in recognition can allow difficulties in communication, participation, learning, caregiver confidence and access to support to compound before a plan is in place.

The guideline also locates peak brain **plasticity** in the **birth-2 year period**. For the psychiatrist, this is a reason to act on a credible developmental concern without waiting for every diagnostic uncertainty to disappear. Action may consist of developmental assessment, parent guidance, a medical or sensory referral, educational planning, or help to stabilise an overwhelmed caregiving environment. The exact package must follow the child's formulation. Early intervention is a principle of timely, proportionate response, not a justification for indiscriminate treatment.

Clinical urgency is often obscured by diagnostic anxiety. Families may be told to “wait and see” because a child is young, while professionals fear overcalling a disorder. The better distinction is between caution about labels and inaction about needs. One can remain cautious about diagnosis while actively documenting function, supporting caregivers, arranging relevant evaluations and reviewing change. This is especially important when the child is not yet able to give a full account of internal experience and when the family's ability to navigate services is limited.

26.5 The psychiatrist's role within a non-psychiatric platform

RBSK does not ask the psychiatrist to duplicate general screening. It creates an opportunity for consultation where a child's health finding has psychological, behavioural, developmental or family consequences. The psychiatrist should frame the referral question before deciding the scope of assessment: Is the immediate need clarification of behaviour, support for caregiver coping, evaluation of emotional symptoms, coordination around developmental function, or advice to another service? This protects the child from a broad but unfocused work-up and protects the family from receiving contradictory explanations.

Several principles keep this consultation clinically sound:

- Begin with function in home, learning and peer contexts, rather than with a label carried on the referral card.
- Seek the child's perspective in a developmentally appropriate manner, alongside caregiver and other relevant accounts.
- Separate the emotional effect of a health or developmental concern from symptoms that require their own psychiatric formulation.
- Return a plan that names who will do what, what the family should watch for, and how uncertainty will be reviewed.

This is also where the limits of the platform should be stated honestly. A screening pathway can identify risk or need for further attention, but it cannot substitute for the comprehensive child psychiatric assessment described elsewhere in this chapter. Nor should it be used to re-teach the childhood disorders themselves. When a disorder-specific question becomes central, use the relevant disorder chapter for diagnostic and treatment detail, while retaining the service pathway as the means of linking the child and family to care.

The multidisciplinary implication is practical. Families often experience services as multiple doors, each with a different language and waiting process. The psychiatrist can reduce this burden by translating findings into everyday goals and by ensuring that psychiatric recommendations fit, rather than compete with, developmental, medical, educational and social interventions. A medication decision, if one is eventually indicated, belongs within the child psychopharmacology framework rather than being inferred from an RBSK category.

PITFALL

Do not let a referral label become the child's identity. A programme finding may explain why a child needs further attention, but it does not establish the cause of behaviour, define family capacity, or predict outcome. Record the observed concern and its functional impact before making psychiatric inferences.

26.6 Writing and answering about RBSK with precision

A strong service answer follows the child's journey. Introduce RBSK and the 4Ds, explain screening through Mobile Health Teams in child-contact settings, identify the DEIC as the district hub for coordinated management, and distinguish the wider screening scope from the

primary early-childhood DEIC focus. Then add the clinical implication: early identification only matters when referral, family understanding and follow-up turn it into usable care. This sequence demonstrates that the candidate understands both policy language and what it changes in practice.

Be equally precise about what the programme does not establish. It does not make a psychiatric diagnosis, replace a developmental formulation, or remove the need for disorder-specific assessment and treatment. It does, however, create a structured opportunity to identify children whose needs may otherwise remain invisible. In a service-based chapter, that is its central contribution: it converts an isolated concern into a route that can be followed, clarified and coordinated.

> RBSK uses the 4Ds to identify childhood health concerns and link them to care; the psychiatrist turns a referral into an individual, developmental and family-centred plan.

27 · Integrated Child Development Services and child mental health policy in India

Why this matters clinically. A young child rarely arrives at a psychiatric service because someone has already named a mental-health problem. The concern is more often expressed as difficult behaviour, poor participation in play or learning, feeding trouble, an unresponsive child, a worried caregiver, or a pattern of missed developmental opportunities. The **Anganwadi Services** platform, formerly described as ICDS, matters because it is a continuing child-development contact rather than a specialist clinic. It can make concern visible early, place it in the child's family and nutritional context, and create a route from concern to an appropriate health or developmental response.

For the psychiatrist, this is not a substitute for child psychiatric assessment, a diagnostic service, or a treatment programme. It is a service platform through which health, nutrition, early learning and caregiver contact can be connected. A good answer therefore does not claim that an anganwadi worker diagnoses a disorder. It explains how a developmental platform can notice difficulty, support the caregiver, reduce practical barriers to care, and help a family reach the service that must take responsibility for assessment or treatment.

27.1 The anganwadi platform as a mental-health opportunity

Child mental health in a public system begins before the consulting room. Emotional regulation, communication, play, attention, attachment and behaviour are lived out in ordinary routines. A platform that sees the child in relation to food, play, caregivers and early learning can therefore detect a mismatch between what the child appears able to do and what daily participation demands. This is a developmental opportunity, not a licence to convert every variation into illness.

The useful policy question is practical: what should happen when an adult who knows the child notices that participation has become difficult or that a caregiver is struggling? The answer is a sequence of listening, documenting the concern in plain language, considering whether health or

developmental factors may be relevant, discussing it respectfully with the caregiver, and linking the family to the appropriate service. The specialist's role is to make that pathway clinically intelligible and humane. A referral letter that only says “behaviour problem” abandons the very context that makes the referral useful.

RULE **Use the anganwadi as a bridge into care, not as a diagnostic endpoint.** Its value lies in sustained contact with the child and caregiver, followed by an accountable link to the service that can assess and respond.

There is also a preventive logic. When caregivers receive understandable support around routine, play, communication and help-seeking, they may be better able to act before strain hardens into conflict, exclusion or repeated non-attendance. This is not a claim that one worker or one service can prevent all psychiatric morbidity. It is an argument for locating mental-health work within the child's actual environment, rather than waiting for distress to become severe enough to cross a specialist threshold.

IN INDIA

The anganwadi is especially important as a shared local point of contact. A psychiatrist should ask whether the child attends, what the caregiver has been told there, and whether the family would accept a coordinated conversation. This preserves continuity between clinic advice and daily life without asking a non-specialist platform to carry a specialist clinical burden.

27.2 The integrated package of services

The programme is built around an **integrated package**, rather than a single intervention. It contains **six** services. For clinical reasoning, the list matters less as an enumeration than as a reminder that behaviour and development should not be detached from nutrition, health access, caregiver knowledge or opportunities for early learning.

SERVICE IN THE PACKAGE	WHY IT MATTERS TO A CHILD-MENTAL-HEALTH FORMULATION
Supplementary nutrition	It keeps nutrition within the clinical context when a child presents with low energy, irritability, feeding difficulty or reduced participation.
Pre-school non-formal education	It provides a natural setting in which play, participation, communication and separation from the caregiver may be discussed.
Nutrition and health education	It creates a caregiver-facing channel for simple, non-stigmatising discussion of routines and help-seeking.
Immunization	It illustrates that some elements of the package depend on connection with the health system rather than stand alone at the centre.
Health check-up	It encourages the clinician to keep physical and developmental contributors in view when a behavioural concern is raised.
Referral services	It is the operational route by which a concern can move beyond observation to a service with the needed competence.

The integration is clinically useful because the same presentation can have multiple meanings. A child who is quiet in a group may be temperamentally reserved, physically unwell, fearful, communication-impaired, poorly nourished, overwhelmed by demands, or distressed by adversity. The platform should not decide among these possibilities by label. It should preserve observations, ask what has changed, involve the caregiver and create a route for further evaluation when the concern persists, impairs participation, or raises safety concerns.

- Describe what is observed before attaching a diagnostic explanation.
- Ask about the child's everyday routine, participation and the caregiver's understanding of the difficulty.
- Record what action was agreed, who will make contact, and what information needs to travel with the referral.

PLATFORM	BRIDGE	TASK
CHILD-DEVELOPMENT CONTACT	CAREGIVER TO SERVICE	NOTICE, LINK, FOLLOW THROUGH

27.3 Age focus and the clinical frame

The core child focus is **0-6 years**. This makes the platform particularly relevant to the early period in which a clinician often has to work from observation, caregiver report and the child's functioning in familiar settings. It also explains why the language of policy should remain child-development language: routine, play, communication, feeding, sleep, interaction and participation can be discussed without prematurely converting the child into a diagnosis.

A psychiatrist should resist two opposite errors. The first is to romanticise early childhood and dismiss meaningful impairment as a phase. The second is to make a categorical psychiatric diagnosis from a brief community observation. The platform is most valuable when it supports **developmentally informed observation**: what the child does across situations, what caregivers notice, what appears to help, what worsens the difficulty, and whether the child can participate in expected daily life.

Caregiver engagement is central here. Advice that ignores food insecurity, caregiving burden, transport difficulty, family conflict, stigma or a caregiver's own distress is unlikely to be carried into the home. The service contact can instead become a place where the caregiver is treated as an informant and partner. That stance is clinically safer than presenting professional opinion as a verdict on parenting.

TRAP **Do not mistake a programme contact for a completed mental-health assessment.** A familiar setting can yield valuable observations, but formulation, diagnosis and treatment decisions require the child psychiatric assessment framework.

27.4 Working with the Anganwadi Worker

The **Anganwadi Worker** is a named provider for supplementary nutrition for children aged **3 to 6 years**. That narrow, verified statement is enough to make an important clinical point: the worker's relationship to the child and caregiver is embedded in ordinary service use. The psychiatrist should build on that relationship without turning the worker into an informal mental-health technician.

Useful collaboration is specific. With caregiver agreement, the clinical team can ask for concrete observations about attendance, participation, interaction with peers and adults, response to routines, and changes from the child's usual pattern. It can then return equally concrete advice: what the family has agreed to try, what signs should prompt renewed contact, and whether the worker's support is limited to encouragement, observation or helping the family navigate a referral. Vague requests to “monitor behaviour” invite judgement and inconsistent reporting.

GOOD TO REMEMBER

When writing to a community contact, state the function rather than the diagnosis: “please note participation in play and response to routine” is more useful and less stigmatising than asking the worker to verify a psychiatric label.

Confidentiality and dignity still apply. Community collaboration is not a reason to circulate a child's clinical history. Share only the information necessary for the agreed task, speak with the caregiver rather than around them, and avoid language that brands the child as difficult, abnormal or dangerous. If there is a safeguarding concern, the clinical response and legal duties belong to the child-protection pathway discussed elsewhere in this chapter, not to informal management at the centre.

27.5 Referral, follow-through and policy translation

The point of referral is continuity. A referral becomes useful only when it carries enough context for the receiving service to understand why the concern arose and when the family can realistically complete the next step. A **functional referral** identifies the observed concern, relevant changes, caregiver concerns, actions already attempted and the reason a further opinion is needed. It does not require the community worker to make a diagnostic claim.

For the psychiatrist, policy translation means turning a broad platform into a usable local pathway. That pathway should identify who speaks to the caregiver, where the child should go next, how feedback returns to the family, and who notices if contact is lost. The details will vary by locality and service availability. What should not vary is ownership: a child should not be passed from one doorway to another because each service assumes that referral alone completes care.

- Make the next contact understandable to the caregiver, including its purpose and practical requirements.
- Use plain descriptions of concerns so that the family can repeat them accurately to the receiving service.
- Seek **closed-loop communication** where feasible: confirmation that contact occurred, clarification of the next responsibility, and renewed outreach when the plan has failed.

MNEMONIC

LINK

Listen to the caregiver, **I**ntegrate the child's daily context, **N**avigate to the appropriate service, and **K**eep responsibility visible until the next link is made.

Existing school mental-health work and the RBSK screening platform may be named as neighbouring parts of the wider child-service environment, but their structures and methods are distinct. Similarly, specialist treatment, early intervention and educational support require their own assessment and service pathways. The exam-worthy point is coordination: a platform is useful when it makes the right next contact more likely, not when it claims to contain every needed intervention.

PITFALL

Do not use the word “referral” as if it ends clinical responsibility. A slip of paper, an instruction to “go to hospital”, or an uncontextualised label can leave a caregiver unable to act. The clinically meaningful unit is a referral that the family understands and a pathway that can recognise non-completion.

27.6 How to write the service answer

A strong service answer begins with the platform's purpose, states the service package, and then explains its mental-health relevance through early recognition, caregiver engagement, contextual observation and referral. It distinguishes the function of a community child-development service

from the function of a specialist mental-health team. It also avoids the false choice between medical and social explanations: both may matter to a child's participation, and the service platform is designed precisely to keep these domains in conversation.

In practice, the psychiatrist's contribution is often to improve the quality of the handover. The medical record should translate complex formulation into a small number of observable goals, while preserving diagnostic nuance within the clinical team. The community contact should receive only what is needed to support the caregiver and the agreed plan. Where a child needs specialist assessment, the relevant assessment, treatment and protection chapters should guide that work; the anganwadi platform remains the local bridge, not the place where those specialised functions are reproduced.

> Anganwadi Services are an integrated child-development platform whose mental-health value lies in contextual observation, caregiver partnership and a reliable bridge to appropriate care.

Child protection, abuse and juvenile justice

28 · Types of child abuse (physical, sexual, emotional, neglect)

Why classification matters clinically. A child-protection formulation begins by naming the kind of harm that is being considered. Vague labels such as “a difficult home” or “poor parenting” can conceal the central question: has a child been harmed, or placed at risk of harm, within a relationship in which an adult or another person holds responsibility, trust, or power? **Child maltreatment** gives the clinician a vocabulary for making that distinction. It is not a diagnosis, an accusation, or a prediction of how a family will be judged. It is a protection concept that keeps the child’s health, survival, development and dignity in view.

The WHO framing applies to children **under 18 years of age**. It places apparently different experiences within a shared clinical frame: harm may be enacted on the body, imposed through sexual violation, communicated through degrading or frightening relationships, or created by a failure to provide necessary care. The categories are useful because they direct attention to the pathway of harm. They are not mutually exclusive boxes. The strip below names the four pathways that carry distinct clinical indicators; commercial and other exploitation is the fifth element of the same definition and is set out in the comparison table rather than the strip. The operational descriptions in this section are explanatory synthesis for teaching, not definitions established by the cited row, and the fragment records that as a declared gap. A child may live with several forms at once, and the most damaging feature may be the cumulative pattern rather than the event that initially brought the family to attention.

PHYSICAL	SEXUAL	EMOTIONAL	NEGLECT
HARM THROUGH ILL-TREATMENT	VIOLATION AND SEXUAL EXPLOITATION	HARM WITHIN RELATIONSHIPS	HARM THROUGH UNMET CARE AND NEGLIGENCE

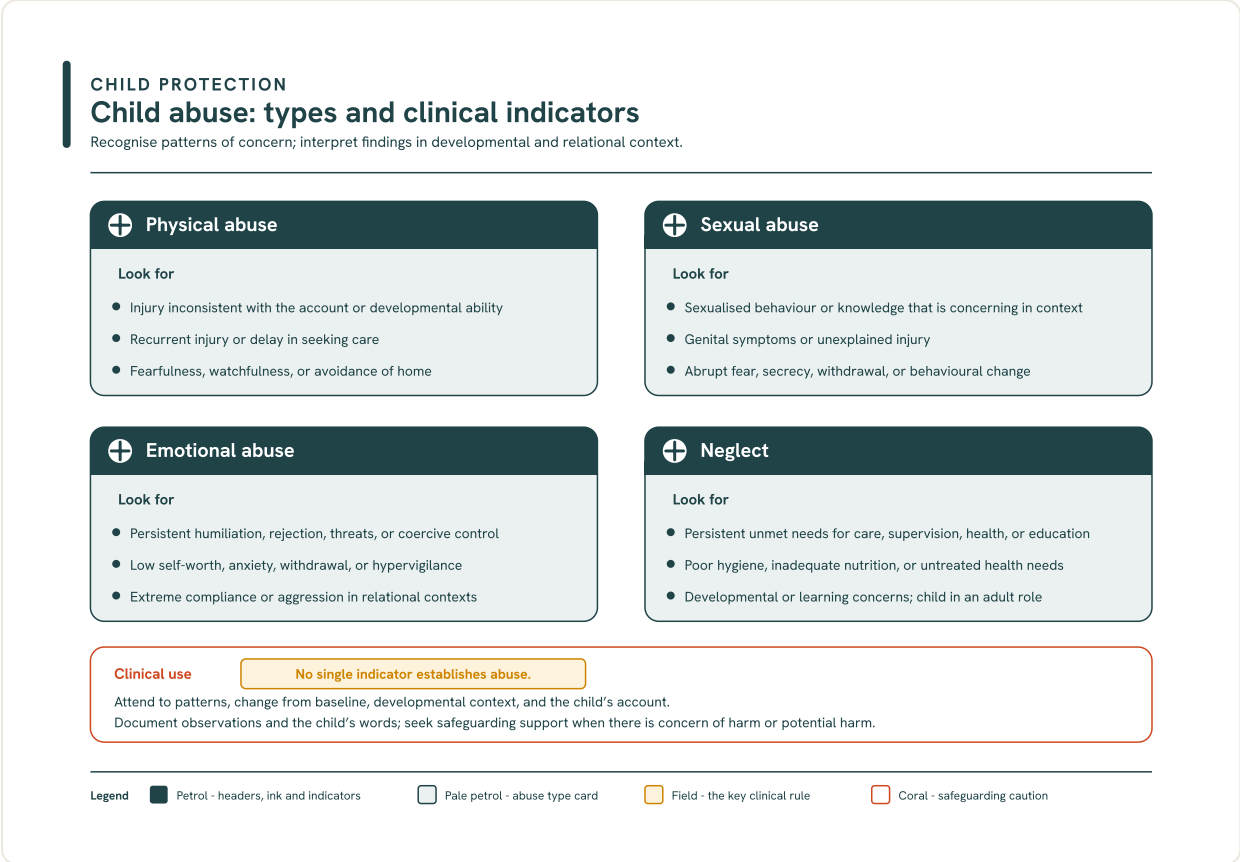

Fig 24.12. The types of child maltreatment set against the clinical indicators that should raise concern. An indicator is a reason to look further and to act on safety, never a finding of fact on its own.

28.1 The organising idea: maltreatment is relational harm

The key to the definition is not simply that a child is distressed or injured. Children can be distressed by illness, bereavement, poverty, conflict, developmental difference and many other adversities. Maltreatment concerns harm that occurs in a **relationship of responsibility, trust or power**. This directs attention to the asymmetry between the child and the person or system on which the child depends. The question is therefore not whether an adult intended to be cruel, but whether the relationship has exposed the child to harm or failed to protect the child from it.

That relational emphasis prevents errors in opposite directions. Narrowing abuse to an obviously violent act can overlook chronic humiliation, coercive sexual conduct, abandonment of care, or exploitation. Treating every imperfect interaction as maltreatment is equally unhelpful. Clinical thinking must hold context without making context an excuse. A parent may be exhausted, frightened, unwell or materially constrained; these circumstances can help explain a pathway, but they do not erase the child's experience of danger, deprivation or degradation. The task of classification is to describe what has happened to the child before attempting to explain why it has happened.

RULE **Classify the pathway of harm before you interpret the family's intention.** Physical, sexual, emotional, neglectful and exploitative experiences may coexist, and each describes a different route by which a child's welfare can be compromised.

For teaching and documentation, it is helpful to distinguish the *act or omission* from its *effect*. The same act may be experienced differently according to the child's developmental understanding, dependence, prior experiences and the surrounding relationship. Conversely, the same emotional outcome may arise from different types of maltreatment. This is why classification is a starting point for formulation, not a substitute for it. It gives a shared language to the multidisciplinary team while preserving the need to understand the individual child.

- Describe the child's experience before assigning a family explanation.
- Identify whether the route of harm is an act, an omission, exploitation, or a combination.
- Ask how responsibility, trust or power has shaped the child's freedom and safety.

28.2 Physical abuse: harm enacted on the body

Physical ill-treatment refers to harmful physical acts directed towards a child. Its clinical meaning is broader than visible injury. The body may be used as the site of punishment, intimidation, control or retaliation; a child can learn that safety depends on anticipating an adult's mood rather than on receiving reliable care. The defining concern is the harmful use of physical force or physical treatment within the unequal relationship, not the explanatory story offered after it.

Physical abuse is often imagined as a discrete incident because incidents are easy to narrate. Yet its psychological significance can also lie in the atmosphere it creates: vigilance, fear of making mistakes, concealment, divided loyalties and an altered sense of what care should feel like. The child may protect the caregiver, minimise the event, or describe it as deserved. Such language should not be read as proof that the experience was benign. Children commonly organise their accounts around preserving attachment and avoiding consequences, especially when the person who hurts them is also a source of food, shelter, affection or authority.

Classification also requires restraint. The psychiatrist does not decide the truth of a family narrative merely from a label such as "discipline," "accident," or "misbehaviour." Those words are interpretations. The clinical category asks a prior question: was physical treatment used in a way that harmed the child or placed the child at risk? This keeps the focus on the child without prematurely converting a clinical discussion into a forensic conclusion. Detailed recognition of indicators and the safeguarding response belong in the dedicated sections on clinical indicators and management.

> **GOOD TO REMEMBER**
>
> When a child describes physical punishment, listen for the relational meaning as well as the event. Fear, secrecy, conditional affection and the child's belief that pain is deserved may be clinically important even when the child does not use the word "abuse."

28.3 Sexual abuse: violation of bodily and relational boundaries

Sexual abuse concerns sexual violation of a child and includes sexual conduct that exploits the child's developmental dependence, lack of freedom, or inability to give meaningful agreement. Its defining clinical feature is not restricted to overt force. Secrecy, grooming, inducement, threats,

emotional manipulation and misuse of authority can all shape the child's experience of entrapment. The category is therefore about an adult or more powerful person using the child for sexual purposes, not about whether the child appeared compliant, curious, affectionate, or unable to resist.

This distinction matters because children may not recognise a sexual experience as abusive while it is occurring. They may have been told it is normal, private, loving, deserved, or dangerous to disclose. They may also be frightened of loss, blame or disruption within the family. A clinician should avoid importing adult assumptions about consent, resistance or disclosure into the child's account. Compliance can reflect dependency, fear, confusion, conditioning or an attempt to preserve a crucial relationship. It does not convert exploitation into a voluntary relationship.

Sexual abuse also needs to be kept conceptually separate from its psychiatric sequelae. A child may present with fear, shame, behavioural change, dissociation, somatic distress, sexualised behaviour, mood symptoms or no obvious psychiatric symptom. These presentations are not themselves the definition of sexual abuse, and the absence of a particular presentation does not settle the question. The safeguarding-specific assessment, including how to take an account without contaminating it, is taught in the section on child sexual abuse assessment and psychiatric sequelae. Legal duties and procedures belong in the dedicated statutory section.

TRAP **Do not equate absence of force or apparent cooperation with absence of sexual abuse.** The clinical concept centres on exploitation within unequal power, not on an adult model of freely negotiated sexual choice.

28.4 Emotional abuse: injury communicated through the relationship

Emotional ill-treatment is harm conveyed through how a child is repeatedly regarded, spoken to, controlled, rejected or frightened. It is sometimes called psychological abuse, but the central point is simpler: the child receives an enduring message that safety, worth, belonging or reality itself cannot be relied on. Unlike a physical act, the injury may not be visible to others. Unlike an isolated harsh remark, the concern is the harmful relational pattern and its impact on the developing child.

Emotional abuse can operate through contempt, humiliation, terrorising, scapegoating, isolation, hostility, coercive control, exposing the child to a persistently threatening interpersonal climate, or making affection contingent on compliance. These descriptions should be used as conceptual pathways rather than as a checklist to be mechanically scored. Their common mechanism is an attack on the child's secure sense of self and relationship. A child may adapt by becoming excessively compliant, volatile, withdrawn, perfectionistic, parentified or chronically alert to others' emotional states. Such adaptations can be mistaken for temperament, defiance or maturity unless their relational context is examined.

It is tempting to treat emotional abuse as less serious because there is no obvious physical injury. That is a category error. Emotional maltreatment can be the principal form of harm in a family, but it also commonly accompanies physical abuse, sexual abuse and neglect. It may be embedded in everyday language, threats, denigration or unpredictable caregiving, making it difficult for

children and professionals to name. The psychiatrist's contribution is often to translate a child's diffuse symptoms and relational expectations into a coherent account of how the environment has become psychologically unsafe.

Care is needed not to medicalise ordinary conflict, cultural difference, an impatient exchange, or the caregiver's understandable distress. The clinical question is whether a pattern of interaction is degrading, frightening, rejecting, controlling or otherwise harmful to the child. That question remains child-centred while allowing a compassionate understanding of family stress. The aim is neither to moralise nor to excuse, but to identify the relationship that the child is having to survive.

PITFALL

Do not dismiss emotionally harmful parenting as merely "a family style" because it lacks a visible injury. Conversely, do not label every family disagreement as emotional abuse. The formulation turns on the child's sustained experience of harm within a dependent relationship.

28.5 Neglect: harm through omission of care and protection

Neglect is the failure to provide or secure care, protection or responsiveness that a child requires. It is often misunderstood as the passive counterpart of abuse. In fact, omission can be an active source of harm: the child is left without reliable attention to basic needs, safety, health, emotional availability, supervision or access to necessary support. Neglect is therefore not defined by a caregiver's emotional distance alone, nor by material hardship alone, but by the child's unmet needs in a relationship where care should be organised.

This category demands especially careful reasoning. Some families face severe constraints and may genuinely lack resources, services, housing security or support. A child can be harmed by deprivation even where no caregiver wishes harm. The clinician should recognise that structural adversity and neglect may coexist without collapsing them into the same moral judgement. What matters for the classification is the lived pattern of unmet need, the available caregiving capacity and whether those responsible for the child are failing to protect or seek help in ways that expose the child to avoidable harm.

Neglect may be physical, emotional, educational, medical or supervisory in its expression, but these are ways of thinking about the area of unmet need rather than separate diagnoses. Emotional neglect deserves particular attention in psychiatric practice. A child may be fed, clothed and attending school while receiving little comfort, attunement, protection or response to distress. Such a child can appear outwardly cared for and yet experience relationships as unavailable or unreliable. Conversely, a caregiver's temporary inability to meet every need during crisis should be understood in context rather than assumed to establish a chronic pattern.

Because neglect often unfolds gradually, it can disappear into the background of a family story. The child may not complain because there is no remembered alternative. Professionals can also become habituated to low expectations for a child who is described as "independent" or "used to managing." A developmentally inappropriate burden of self-care is not evidence of resilience by

itself. It may be an adaptation to the absence of dependable adult care. The precise indicators and intervention pathway should be sought in the subsequent protection sections rather than inferred from this classification alone.

- Ask what the child needs in order to be safe, cared for and emotionally held.
- Ask which of those needs are persistently unmet and how the child compensates.
- Keep structural deprivation in the formulation without allowing it to obscure a child's unmet need for protection.

28.6 Overlap, cumulative burden and exploitation

The categories should be distinguished in order to be recognised, then brought back together in formulation. A child who is physically harmed may also be threatened and humiliated. Sexual abuse may be sustained by emotional manipulation and by the neglect of adults who fail to notice or protect. Neglect may coexist with a climate of rejection that makes it emotionally abusive as well. Recording only the most dramatic type can flatten the child's experience and can lead the team to miss the mechanism that keeps the harm in place.

TYPE	CENTRAL PATHWAY OF HARM	QUESTION THAT SHARPENS FORMULATION	COMMON INTERPRETIVE ERROR
Physical ill-treatment	Harm enacted through physical treatment	How is force, pain or bodily control being used in the relationship?	Reducing the account to an isolated injury
Sexual abuse	Sexual violation or exploitation of dependency	How are power, secrecy, inducement or coercion shaping the child's freedom?	Reading compliance as consent
Emotional ill-treatment	Harm conveyed through the relational environment	What repeated message about safety, worth or belonging does the child receive?	Ignoring harm because it is not visible
Neglect and negligence	Harm through unmet care, protection or responsiveness	Which needs remain unmet, and how does the child manage without dependable care?	Confusing material adversity with the whole formulation
Commercial or other exploitation	Harm through use of the child for another's gain	Who benefits from this child's labour, body, image or dependency?	Treating exploitation as a social problem outside the clinical formulation

The WHO framework also includes **commercial or other exploitation**. This reminder matters because a child can be harmed when another person gains from the child's vulnerability, labour, body, image, access, status or dependency. Exploitation may overlap with physical, sexual, emotional and neglectful maltreatment, but it directs attention to the use of the child for

another's benefit. The clinician need not force every experience into a single label. A better formulation states the principal pathways and explains how they interact.

MNEMONIC

Body, boundaries, belonging, basics, benefit

Use this as a brief bedside prompt: physical ill-treatment concerns the body; sexual abuse violates boundaries; emotional ill-treatment attacks belonging and safety; neglect and negligence leave the basics of care and protection unmet; exploitation turns the child into another person's benefit. It is a memory aid, not a substitute for a child-centred formulation.

28.7 Language, formulation and the limits of classification

Precise language protects the child and the clinical record. "Abuse" is a useful umbrella term in teaching, but a formulation should say what is meant: physical ill-treatment, sexual abuse, emotional ill-treatment, neglect, negligence or exploitation. The WHO description explicitly includes **negligence** alongside abuse and neglect. Naming the pathway avoids euphemism, but it should not turn a child's complex account into a label that speaks over them. Whenever possible, retain the child's own words alongside the clinician's conceptual description.

Classification has limits. It does not determine credibility, identify an alleged perpetrator, establish legal liability, replace a developmental assessment, or dictate the immediate safeguarding response. It also does not tell the clinician the child's psychiatric diagnosis. The WHO scope remains the child **under 18 years of age**, but the category alone does not explain that individual child's developmental needs or psychiatric presentation. The disorders that may be relevant to a child's presentation are addressed in the Child behavioural, emotional and other disorders notes and the Intellectual disability and autism spectrum disorder notes. Normal developmental context belongs in the Normal child development and milestones notes. Here, the aim is narrower and foundational: recognise the form of maltreatment without losing the person inside the category.

IN INDIA

In Indian practice, family, school, neighbourhood and extended-kin settings can all shape how a child describes harm and whom the child believes can be told. Use plain, non-accusatory language when eliciting the child's account, while keeping the clinical formulation explicit. Cultural sensitivity should improve understanding of context; it must not make coercion, degradation, sexual violation or unmet care invisible.

A useful final distinction is between classification and response. The present section helps the clinician identify the type of maltreatment. Recognition of clinical indicators is covered separately; child sexual abuse assessment and psychiatric sequelae have their own section; statutory obligations are addressed in the dedicated statutory section; and the safeguarding response is covered in the management and intervention section. This division is deliberate. In practice these tasks are connected, but clear conceptual boundaries prevent a rushed label from becoming a substitute for careful assessment, protection and treatment.

Child maltreatment is best understood as harm or threatened harm within a relationship of responsibility, trust or power: name the pathway - physical, sexual, emotional, neglectful or exploitative - then formulate the child's whole experience.

29 · Clinical features and indicators of child abuse

Why it matters clinically. Abuse is often first encountered as an ordinary clinical presentation rather than as a declared safeguarding concern. The child may be brought for pain, a change in behaviour, a poorly explained injury, or a difficulty noticed by another adult. The psychiatrist's contribution is not to convert a sign into an accusation. It is to recognise when the presentation cannot safely be treated as routine, to distinguish observation from interpretation, and to preserve the child's account and the clinical evidence with care.

Clinical indicators are signals for concern, not diagnostic labels. Their value lies in the relationship between the observed finding, the account offered for it, the child's developmental capacities, and the wider clinical context. An unexplained or patterned injury, a disclosure, or a behavioural change can each be clinically important. The central question is not whether a clinician can prove abuse in the consulting room. It is whether the available information makes a benign account inadequate and requires the presentation to be held as a possible protection concern.

29.1 The purpose and limits of clinical indicators

An indicator is a feature that should alter clinical attention. It may arise from the body, the history, the child's words, behaviour, or the relation between these sources. It does not identify a perpetrator, establish intent, or settle a legal question. This distinction protects both the child and the quality of clinical reasoning. A clinician who dismisses concern because one feature is non-specific may miss the pattern. A clinician who treats one feature as conclusive may contaminate an assessment, harden an uncertain narrative into a fact, and cause avoidable distress.

The useful mental move is from isolated sign to coherence. Ask what has been observed; what account is being given; whether the account can plausibly explain the observation; and whether the child can meaningfully corroborate, contradict, or qualify it. This is a reasoning task, not an exercise in detecting a particular kind of family. Abuse can be concealed within an apparently coherent story, while an anxious or inconsistent caregiver may still be describing an accidental event. The clinical standard is disciplined curiosity: neither premature reassurance nor premature certainty.

RULE **Read the finding and the explanation together.** A mark on the body is clinically meaningful in relation to its pattern, the account of how it arose, the child's capacities, and the rest of the presentation.

Indicators should also be understood as prompts to slow down. In ordinary practice, time pressure encourages rapid closure: a plausible explanation is accepted, the injury is coded, and

attention shifts to symptom relief. Protection work requires the opposite habit when concern is raised. The practitioner separates what was seen from what was reported, records uncertainty honestly, and avoids allowing the emotional force of a case to replace careful description. This is especially important in psychiatry, where behaviour may be quickly attributed to temperament, stress, or a psychiatric disorder even when the change requires a broader safeguarding lens.

OBSERVE	COMPARE	CONTEXTUALISE
WHAT IS PRESENT	ACCOUNT WITH FINDING	DEVELOPMENT AND PRESENTATION

29.2 Pattern as clinical evidence

Patterned bruising is a particularly important physical indicator because the morphology of the mark can retain information about the force or object involved. Clinical recognition guidance treats bruising in the shape of a **hand or ligature**, **stick, teeth mark, grip or implement** as a reason to suspect maltreatment. The teaching point is not that every such mark determines the history. It is that a recognisable pattern should make an unexamined explanation feel insufficiently safe.

Describe before interpreting. The record should preserve the clinician's own observations in plain language, including what made the mark appear patterned, rather than replacing description with a conclusion. A conclusion can later be tested against examination, photographs where lawfully obtained, medical opinion, and the evolving history. A vague note such as “bruise present” loses the very feature that generated concern. Equally, a categorical note that labels an injury as abuse overstates what the observation alone can establish.

Pattern matters because accidental histories commonly describe an event, whereas a patterned mark invites attention to the means by which force may have been applied. That is a clinical inference to examine, not a shortcut to judgment. The account should be heard without coaching or adversarial questioning. The psychiatrist may need to acknowledge that a caregiver's narrative is emotionally compelling while still recognising that it does not answer the physical question raised by the finding.

GOOD TO REMEMBER

When an injury is concerning, the most useful note separates observation, reported history, and clinical interpretation. This preserves both the uncertainty and the reason concern was raised.

A pattern can be missed when the consultation is framed around an apparently unrelated symptom. A child may be distressed, withdrawn, irritable, or reluctant to be examined. The task is not to search the body indiscriminately, but to allow physical findings that are already apparent or clinically relevant to alter the assessment frame. The psychiatrist should remain alert to the possibility that emotional and physical data belong to the same presentation without assuming that they do.

29.3 The unsuitable explanation test

A clinician should be concerned by **bruising or petechiae** that are not explained by a medical condition when the history offered is unsuitable. This is a combined test. The physical finding must be considered alongside medical possibilities and the account of its occurrence. It is not sound practice to infer maltreatment merely because a bruise has no immediately obvious cause. Nor is it safe to accept a history merely because it is confidently delivered.

An **unsuitable explanation** is one that is **implausible, inadequate or inconsistent**. In practice, the explanation is examined against the presentation, the child's ordinary activities, any relevant medical condition, and developmental stage. An account may be unsuitable because it does not describe a mechanism capable of producing the observed finding, because essential elements change, or because it asks the child to have done something outside their capacities. The point is not to demand a perfect story from frightened adults. It is to notice when the story does not carry the clinical weight placed upon it.

CLINICAL QUESTION	WHAT IS BEING EXAMINED	WHY IT MATTERS
What is observed?	The finding itself, described without conclusion.	It keeps the record anchored to evidence.
What account is offered?	The reported sequence and mechanism.	It identifies what is being tested, rather than what the clinician assumes.
Could the account fit?	Its plausibility in the clinical and developmental context.	It reveals whether reassurance is justified.
What else could explain it?	Medical and contextual alternatives.	It prevents both missed illness and over-attribution.

This formulation is deliberately more rigorous than asking whether the adult “seems believable.” Demeanour is a poor substitute for evidence. Fear, shame, anger, exhaustion, language difference, and prior difficult experiences with institutions can all affect how a history is given. Conversely, a calm account can be rehearsed. The clinical work is therefore to compare content with content: the observed presentation, the mechanism described, and the child's developmental context.

TRAP **Do not equate inconsistency with proof.** An inconsistent account increases concern when it cannot explain the presentation; it does not by itself establish why the inconsistency occurred.

Medical uncertainty should not be used as a refuge from safeguarding thought. If a medical condition is possible, it deserves proper consideration. If the account remains unsuitable after that consideration, the presence of an alternative question does not erase the protection question. These lines of reasoning can proceed together. Psychiatry contributes by resisting simplistic psychological explanations for either the child or the caregiver, and by keeping the formulation open enough for new information to matter.

29.4 Hidden injury and delay in seeking care

Concern is heightened when a child has an **intra-abdominal or intrathoracic injury** in the absence of major confirmed accidental trauma and there is no explanation, an unsuitable explanation, or **delay in presentation**. This is a useful corrective to the visual bias of clinical practice: a serious injury may not declare itself through an external mark. The **absence of external bruising** does not remove concern in this setting.

Delay is not a moral verdict on a caregiver. Families may encounter fear, uncertainty, limited resources, competing demands, or difficulty recognising severity. Its clinical importance comes from the way it interacts with the injury and the history. A delay can be understandable, or it can sit uneasily beside a presentation that requires explanation. The psychiatrist should avoid transforming this indicator into an accusation about care-seeking. Instead, it should prompt careful clarification of what was noticed, when concern arose, what changed, and how the family understood the child's condition.

The same discipline applies to the absence of an explanation. “No explanation” may mean that nobody asked in a way the child could understand, that the available adult does not know, that communication is difficult, or that an account has not yet emerged. It is an important clinical state, but not a completed conclusion. A quiet, non-leading approach protects the integrity of what the child says and avoids making the consultation into an interrogation.

> **PITFALL**
>
> Do not let an unremarkable skin examination create false reassurance when the clinical presentation raises concern about internal injury. Visible and invisible evidence do not have the same relationship in every case.

29.5 Behaviour, preoccupation, and the meaning of a disclosure

Behavioural indicators demand particular restraint because behaviour is meaningful but rarely self-interpreting. A behavioural change may signal distress, but it is not an abuse determination. The psychiatrist should ask whether the change fits the child's broader presentation and whether it is accompanied by other concerning information. Its value is often as a reason to listen more carefully, rather than as a label placed on the child or family.

A **disclosure** is itself a high-risk clinical signal. It should not be dismissed because it is difficult to hear, incomplete, or not immediately corroborated in the consultation. The clinician must distinguish the child's communication from the clinician's interpretation of it. Detailed evaluation of a possible sexual-abuse disclosure belongs to the child sexual abuse assessment and psychiatric sequelae section; the present task is recognition without premature conclusion.

In a **pre-pubertal child**, **repeated or coercive sexualised behaviours or preoccupation** should raise suspicion of maltreatment, particularly sexual abuse. The term requires careful use. It does not refer to a clinician's discomfort with a child, a family, or a topic. It describes behaviour or preoccupation whose repetition or coercive quality makes it a protection indicator in the relevant

developmental context. The child should not be shamed, labelled, or treated as responsible for the concern raised by their behaviour.

There is a vital distinction between recognising an indicator and conducting a sexual-abuse assessment. The latter is a specialised safeguarding evaluation and is addressed in the child sexual abuse assessment and psychiatric sequelae section. The general child psychiatric assessment framework is set out in the assessment section of this chapter. Here, the responsibility is narrower and earlier: notice the signal, take it seriously, avoid contaminating the account, and do not reduce it to a disorder label.

MNEMONIC

See, hear, separate, preserve

See the finding, **hear** the account, **separate** observation from inference, and **preserve** the child's words and the clinical uncertainty.

29.6 Integrating indicators without overreach

Integration means asking whether different pieces of information support, contradict, or leave unanswered the working account. Physical findings, behaviour, the child's communication, the reported mechanism, and the timing of presentation should not be pooled into a dramatic narrative merely because each is concerning. They should remain distinguishable. A strong formulation names what is known, what is reported, what is inferred, and what remains uncertain. This form of precision is clinically protective: it permits later reviewers to see the reasoning rather than inherit an unsupported conclusion.

The psychiatrist should also be alert to diagnostic overshadowing. A pre-existing developmental, behavioural, emotional, or physical difficulty can become an all-purpose explanation for new concerns. It should instead be treated as context. It may affect communication, examination, emotional expression, and the way adults understand the child; it does not make the child less deserving of a safeguarding formulation. For normal temperament, developmental norms and milestones, see the Normal child development and milestones notes. For childhood disorders themselves, see the Child behavioural, emotional and other disorders notes.

Conversely, safeguarding concern must not become a substitute diagnosis for every presentation involving adversity. The child may need a psychiatric formulation for distress and impairment while the facts around possible abuse remain incomplete. Holding both truths prevents a false choice between “mental health problem” and “protection problem.” It also prevents the clinician from allowing a familiar diagnosis to close inquiry into a newly concerning sign.

REASONING ERROR	WHY IT FAILS	BETTER CLINICAL POSITION
One sign is decisive	Indicators are not equivalent to proof.	State the concern and the evidence that supports it.
One benign possibility ends inquiry	Possibility is not explanation.	Test whether it accounts for the actual presentation.
Behaviour explains the injury	Psychiatric formulation can obscure physical evidence.	Keep physical and psychological observations in view.
Inconsistency explains motive	Clinical observation cannot infer intent from discrepancy alone.	Record the discrepancy and retain uncertainty.

Language matters. “Alleges,” “claims,” and “admits” can insert judgement into the record. Neutral attribution is usually better: “the child said,” “the caregiver reported,” “the clinician observed.” Such wording does not weaken the seriousness of a concern. It makes clear whose information is being recorded and protects against an assessment becoming more certain on paper than it was in the room.

29.7 Indian clinical use of recognition guidance

IN INDIA

The indicator set used here is clinical recognition guidance drawn from **NICE** guidance. It should not be presented as an Indian statutory or national standard. The clinical signs remain useful because recognising concern precedes the locally governed protection response; the legal and service pathway is addressed in the protection sections of this chapter.

For the Indian postgraduate reader, the practical implication is modest but important. Use the indicators to improve recognition and documentation, not to borrow a foreign legal framework. A psychiatrist may encounter the child in a general hospital, outpatient setting, school-linked service, or mental-health service. The setting changes access to collateral information and the immediate clinical environment, but it does not change the need for careful observation, respectful listening, and disciplined language. What happens after recognition belongs to the management and statutory sections, not to the indicator list itself.

Cultural humility is part of clinical accuracy. Family practices, language, privacy, and power differences affect what can be asked and what will be said. They must not become reasons to lower the threshold for attentive listening, nor reasons to pathologise unfamiliar family life. The clinician should maintain the same evidentiary discipline across families: attend to the observed presentation, evaluate the suitability of the account, and acknowledge uncertainty where it remains.

29.8 A defensible clinical formulation

A concise protection-oriented formulation can be written without claiming more than the evidence permits. It identifies the presenting concern, the material indicator, the account offered, the degree to which that account fits the presentation, and the child's current emotional or behavioural state. It then states the level of concern in neutral language. This helps the next

clinician understand why the case could not be treated as routine, while avoiding a forensic conclusion beyond the encounter's scope.

It is equally important to make absence visible. If the child has not provided an account, say so without implying that this reassures. If an explanation is unavailable, say that it is unavailable rather than inventing a reason. If a medical possibility is under consideration, distinguish it from a confirmed explanation. Precision at these points prevents a later reader from mistaking silence for denial, delay for proof, or uncertainty for lack of concern.

- Record what was observed without converting it into a conclusion.
- Record whose account is being reported and where the account does not fit the presentation.

> Clinical indicators of abuse require recognition, not premature conclusion: preserve the finding, test the explanation, hear the child, and keep uncertainty explicit.

30 · Child sexual abuse assessment and psychiatric sequelae

Why this matters clinically. An assessment after suspected or disclosed child sexual abuse is not an exercise in extracting a complete account. It is a psychiatric encounter conducted in the presence of possible trauma, compromised safety, family conflict, and a legal process that may later scrutinise the record. The clinician's first task is to create enough psychological safety for the child to be heard without turning the consultation into an investigation. The second is to identify the child's current needs and formulate a plan that protects both care and the quality of the child's account.

Marks in this area are earned by showing that one understands the distinction between a clinical assessment and a forensic investigation. The psychiatrist contributes careful listening, mental-state assessment, developmental understanding, risk formulation and treatment planning. The psychiatrist does not need to prove the allegation, determine credibility by demeanour, or repeatedly seek detail in the hope that certainty will emerge. For the general child psychiatric framework, including the developmental history and multi-informant approach, see the child psychiatric assessment section.

Listen	Assess	Formulate	Document
THE CHILD'S WORDS	CURRENT SAFETY	PSYCHIATRIC NEED	OBSERVATIONS CLEARLY

30.1 The purpose and stance of the assessment

The useful opening question is not, “Did this happen?” but, “What does this child need from me now?” That question keeps the assessment clinically anchored. A disclosure may be direct, partial, withdrawn, communicated through behaviour, or reported by another person. None of these forms authorises the clinician to infer an event from a single sign. Equally, an apparently calm child, an inconsistent sequence, or an absence of dramatic affect does not settle the matter in the opposite direction. Children communicate under developmental, relational and emotional constraints; the task is to understand those constraints rather than treat them as a test of truthfulness.

A **trauma-informed stance** means that the interview is paced around the child's capacity to participate. It gives the child a sense of control over pauses, clarification and the limits of what can be discussed. It uses language the child can understand, accepts uncertainty, and avoids disapproval, shock or leading reassurance. The clinician should be steady rather than neutral in the cold sense: the child should experience belief that their distress matters, without being supplied a narrative that is not their own.

The assessment has several linked purposes:

- to establish immediate safety and the need for medical or protective action;
- to understand the child's account sufficiently for clinical care while preserving spontaneity; and
- to assess consequences, risks and supports for the child and caregiving system.

RULE **Ask enough to care safely, not enough to conduct the investigation yourself.** Open prompts and reflective listening can clarify the child's immediate needs. Repeated, detail-seeking questioning can overwhelm the child, blur the source of information and make later accounts harder to interpret.

This boundary is clinically protective, not evasive. The psychiatrist may need a concise account of what the child says occurred, when there may have been contact, whether the alleged source of harm remains accessible, and what the child fears will happen next. Those questions serve safety and treatment. A fuller evidentiary account belongs in the appropriate safeguarding and legal pathway. The statutory duties and child-friendly procedures are addressed in the section on the POCSO Act, and the clinical safeguarding response is addressed in the management of child abuse cases section.

30.2 Preparing the setting and beginning the conversation

The setting communicates before the clinician speaks. Privacy, an unhurried pace and a predictable structure reduce the sense that the child is being examined for a performance. Before meeting the child, obtain the referral account, identify those present, and consider whether an accompanying adult may be a source of fear, pressure or information contamination. The child's preference about who remains nearby matters, but it does not replace clinical judgment about safety.

Begin by explaining one's role in plain language: the clinician is there to help with feelings, safety and health; some information may need to be shared to keep the child safe; and the child may say when they do not know, do not remember, need a break, or do not want to answer a question. This is assent-sensitive communication. It is not a legal consent tutorial. It is an everyday clinical method for restoring agency after an experience in which agency may have been compromised.

Rapport should not be mistaken for prolonged informal conversation designed to “win” disclosure. Ordinary topics, play, drawing or an activity may help a younger child regulate and communicate, but they are not diagnostic tests and should not be interpreted symbolically as proof of abuse. The psychiatrist notices how the child uses the activity: whether it permits

engagement, reduces arousal, supports language, or reveals an immediate concern. The methods of play assessment are covered in the play assessment and interviewing children section.

When the child begins to describe an experience, invitation is preferable to suggestion. “Tell me what you mean,” “What happened next?” and “Tell me more about that” preserve the child's language. Questions that offer the answer, supply body terms the child has not used, or repeatedly contrast alternatives can create pressure to agree. Clarification is legitimate when it affects immediate safety, but the clinician should be able to state why each question was necessary.

TRAP **Do not confuse a coherent adult-style chronology with a reliable child account.** Trauma, fear, developmental language and loyalty conflicts can all affect how an account is told. Conversely, apparent detail is not a substitute for careful assessment. The psychiatrist records what was said and the context in which it was said, rather than grading the child as believable or unbelievable.

30.3 Eliciting the account without contaminating it

The core interviewing skill is **narrative invitation**. Let the child start with their concern and follow their language. If the child makes a statement that signals possible sexual abuse, acknowledge it calmly and use open invitations before narrowing where a clinical decision requires it. The distinction is crucial: “Can you tell me more?” invites recall; “Did he do this?” imports a proposition. It is a disciplined interview in which the child's account, rather than the clinician's hypothesis, does the work.

Observe the conditions of disclosure. Note whether the child speaks freely, whether an adult answers for them, whether the child checks another person's reaction, and whether there are interruptions or visible distress. These observations provide context; they are not credibility verdicts. A child may disclose and later minimise, deny, become silent or ask that the matter be kept secret. Such shifts should be recorded with care and explored for their emotional meaning, particularly fear of consequences, attachment to the alleged person, shame or concern about family disruption. They should not be labelled manipulation.

It is useful to separate information into three streams in the notes:

- the child's own words, preferably marked as a direct statement where possible;
- the collateral history and the identity of the person giving it; and
- the clinician's observations, formulation and actions.

This separation prevents an inference from acquiring the appearance of a quotation. It also protects the team from a common drift in complex cases, in which repeated handovers transform a concern into a purported fact. If the child uses unfamiliar words, unusual labels or a gesture, describe them faithfully and avoid translating them into a more definite sexual act unless the child has made that meaning clear. If a physical examination or specialised forensic interview is indicated, the psychiatric record should state the clinical reason for referral rather than attempt to replace that assessment.

PITFALL

Writing “history of abuse” when the information is an unverified report erases the source and certainty of the statement. A defensible record distinguishes disclosure, allegation, collateral report, observed affect and clinical opinion. That precision protects the child as well as the clinician.

30.4 Psychiatric examination and formulation

A **psychiatric formulation** is more useful than a checklist of symptoms because it asks how the child's present difficulties relate to the alleged experience, developmental stage, relationships, prior vulnerabilities and current environment. It should cover affect regulation, sleep, appetite, concentration, fears, avoidance, intrusive experiences, dissociation, anger, behaviour at home and school, peer relationships, bodily concerns, sexualised behaviour, substance use where relevant, and thoughts of death or self-injury. The assessment should also identify strengths: a protective adult, capacity to seek help, meaningful routines, school connection, interests, or a prior ability to recover after stress.

The mental-state examination is adapted to developmental communication. Observe play, movement, speech, attention, facial expression, engagement, thought content and the child's ability to make sense of their feelings. Avoid translating a developmentally typical limitation into psychopathology. A young child may express trauma through clinginess, irritability, regression, nightmares or changed play rather than verbal fear. An older child may present with anger, self-blame, risk-taking, emotional numbing or withdrawal. These are possibilities to examine, not signatures that establish abuse.

Formulation should keep causal language proportionate. The child may have symptoms associated with the experience, symptoms worsened by the response of adults, difficulties that predated the concern, and difficulties produced by the ongoing crisis. The clinician should resist the false choice between “all due to abuse” and “unrelated to abuse.” A formulation can hold several pathways at once and describe what needs treatment now without overclaiming causation.

CLINICAL DOMAIN	QUESTION FOR THE PSYCHIATRIST	REASONING VALUE
Safety	Is there continuing access, intimidation, coercion or fear of return?	Determines urgency and the need to coordinate protection.
Trauma response	What has changed in arousal, sleep, memory, avoidance or sense of safety?	Connects current distress to a treatable pattern without assuming a diagnosis.
Development	How does language, understanding and dependence shape what the child can describe?	Prevents adult expectations being imposed on the account.
Relationships	Who comforts, pressures, disbelieves or protects the child?	Shows whether the environment is buffering or perpetuating distress.
Risk	Are there self-directed, other-directed or escape-related risks?	Links assessment directly to a safety plan.

Why formulation matters. The diagnostic label is only one possible output. In the early phase, an accurate account of distress, risk, functioning and supports may be more clinically useful than premature categorisation. The treatment plan can then address regulation, sleep, family response, school support and specialist referral while diagnostic understanding develops over time.

30.5 Psychiatric sequelae and clinical discrimination

Child sexual abuse can be associated with both immediate and enduring **psychiatric sequelae**. The clinical task is to look actively for harm without assuming that every child will show the same pattern or that the absence of one expected pattern is reassuring. The consequences may sit across health, emotional regulation, behaviour, relationships and development, and may become clearer only as the child's circumstances change.

The health consequences associated with child sexual abuse include **STI**, **traumatic injury** and **unwanted pregnancy**. Their possibility is a reason for integrated medical assessment, not a reason for psychiatrists to make physical findings the sole arbiter of concern. A psychiatric consultation should ask what bodily symptoms mean to the child, whether there is pain, fear, shame or confusion, and whether medical care has been arranged through the appropriate pathway.

Psychiatric and behavioural associations include **substance misuse**, **major depressive disorder**, **PTSD**, **complex PTSD**, **anxiety disorders** and **antisocial behaviours**. These associations should guide enquiry, not become a diagnostic shortcut. The disorders themselves are dealt with in the Child behavioural, emotional and other disorders notes.

There are several discriminations worth making. First, symptoms may be trauma-related without fitting a settled syndrome at the first interview. Second, a psychiatric disorder may be present alongside a normal-range response to extraordinary stress. Third, a symptom may have predated the alleged abuse and still have been exacerbated by it. Fourth, treatment should not wait for a perfect causal model when risk, distress or impairment is evident. The formulation should

therefore describe temporal relationships, maintaining factors and current priorities in plain clinical language.

GOOD TO REMEMBER

Ask about the child's own explanation of change. “What has been hardest since this began?” often reveals sleep disruption, fear of places or people, guilt, worries about pregnancy or infection, and family tensions that a symptom checklist can miss. It also tells the clinician what the child most wants help with.

30.6 Family work, collateral information and confidentiality

The caregiver interview has two functions: it gathers context and it assesses the caregiving environment. Ask what changed, who first noticed it, what the child has said, how adults responded, and whether anyone has coached, threatened, blamed or isolated the child. The clinician must remain alert to the possibility that an apparently supportive adult is also distressed, disbelieving or unable to keep the child safe. Conversely, a caregiver's anger or confusion may reflect fear and helplessness rather than hostility to the child. Assessment should clarify this rather than moralise it.

Confidentiality needs to be explained as a relationship practice, not as a bureaucratic warning. The child should know that private feelings are respected but that information relevant to safety cannot simply be kept between child and clinician. Where information must be shared, tell the child what will be shared, with whom, and why, as far as safety permits. This preserves trust better than making a promise that later has to be broken.

Collateral information from school, relatives or other services should be used purposefully. It may establish changes in functioning, identify a safe adult, or clarify practical risk. It should not become a broad search for character evidence. A child who is struggling academically, behaving aggressively or avoiding school needs support for those problems whether or not the collateral source agrees about the allegation. That distinction keeps the psychiatric role therapeutic.

IN INDIA

Indian practice often requires the psychiatrist to work at the intersection of family dependence, school pressures, medical services and protection systems. Keep the clinical note readable across those settings: record the source of information, the child’s own words, observed distress, immediate risks and the action taken. For the statutory reporting framework and child-friendly legal procedure, see the POCSO Act section; for protection, reporting, referral and treatment coordination, see the management of child abuse cases section.

30.7 Documentation and communication with other systems

Forensic-quality documentation does not mean writing like a lawyer. It means producing a contemporaneous clinical record that another responsible professional can understand without guessing which parts are observation, report or opinion. Use the child's language for key disclosures, record questions that materially shaped the response, identify who was present, and describe affect and behaviour without embellishment. Write “became quiet and looked away”

rather than “appeared guilty”; write “said she was afraid to go home” rather than “home is unsafe,” unless the latter is your clearly stated formulation based on recorded facts.

Document negative findings with the same restraint. “No suicidal thoughts disclosed in this interview” is different from “no suicide risk.” A child may be unable, unwilling or unsafe to disclose. The risk formulation should show what was asked, what was observed, what remains uncertain and how the uncertainty is being managed. Avoid copying language from another professional's record unless its source is attributed. Repetition can make an error look corroborated.

Communication should be need-to-know and clinically purposeful. The psychiatric team may need to coordinate with medical, protection, legal and school systems, but should not casually circulate sensitive details. When handing over, separate the immediate concern, the child’s current mental state, the risks, the supports already in place and the requested action. The precise legal mechanism is outside this section; the psychiatrist's contribution is a clear clinical account and timely coordination.

MNEMONIC

LISTEN

Let the child lead; **I**dentify immediate risk; **S**eparate report from observation; **T**rack trauma and functioning; **E**xplain confidentiality; **N**ote words and actions clearly. It is a memory aid for the clinical posture, not a substitute for safeguarding procedures.

30.8 A practical psychiatric plan after assessment

The assessment should conclude with a plan that answers the child's practical question: “What happens now?” State the immediate safety concern, the mental-health priorities, the support needed from carers, the referrals or coordination required, and the follow-up arrangement. A plan that merely records “counselling advised” fails to show what problem is being addressed or who is responsible for the next step.

Psychological treatment should be matched to the child's presentation, developmental communication and capacity for stability. Early work may focus on safety, emotional regulation, sleep, routine and helping caregivers respond without blame. More focused trauma work requires safety and a shared formulation. When a child presents with a disorder requiring treatment, its disorder-specific management belongs in the Child behavioural, emotional and other disorders notes; this section does not convert abuse assessment into a disorder chapter.

Follow-up revisits both symptoms and context. A child may initially minimise distress, become more symptomatic after disclosure, or deteriorate when contact, family conflict or legal proceedings change. The clinician should invite the child to say what has become easier or harder and re-check risks without making every visit a repeated interview about the alleged event. Continuity itself can be therapeutic when it demonstrates that adults can hear difficult material, act predictably and remain available.

In suspected or disclosed child sexual abuse, the psychiatrist listens carefully, assesses safety and psychiatric need, documents source and uncertainty, and does not turn clinical care into a repeated forensic interview.

31 · POCSO Act 2012 (provisions, mandatory reporting, child-friendly procedures)

Why it matters clinically. A disclosure, a worrying account from a parent, or information suggesting that a child may be at risk can place the psychiatrist at the boundary between therapeutic work and a statutory process. The central examination point is not whether the clinician can prove an offence. It is whether the statutory threshold for **mandatory reporting** has been crossed. In India, the **POCSO Act 2012** makes this a legal duty and sets out a deliberately child-sensitive route from information to investigation and trial.

The Act should be understood as a procedural protection, not as an alternative diagnostic or therapeutic framework. It regulates the public response to suspected offences against a child; it does not ask a psychiatrist to decide guilt, conduct a criminal investigation, or replace the court. Its design matters to clinical practice because a child who has already been frightened, coerced, or disbelieved can be harmed again by a process that demands repetition, confronts the child with the accused, or turns the child's account into an adult summary. The provisions below are therefore best learnt as one coherent pathway: report on the statutory threshold, preserve the child's own account in the appropriate legal process, and protect the child during evidence and trial.

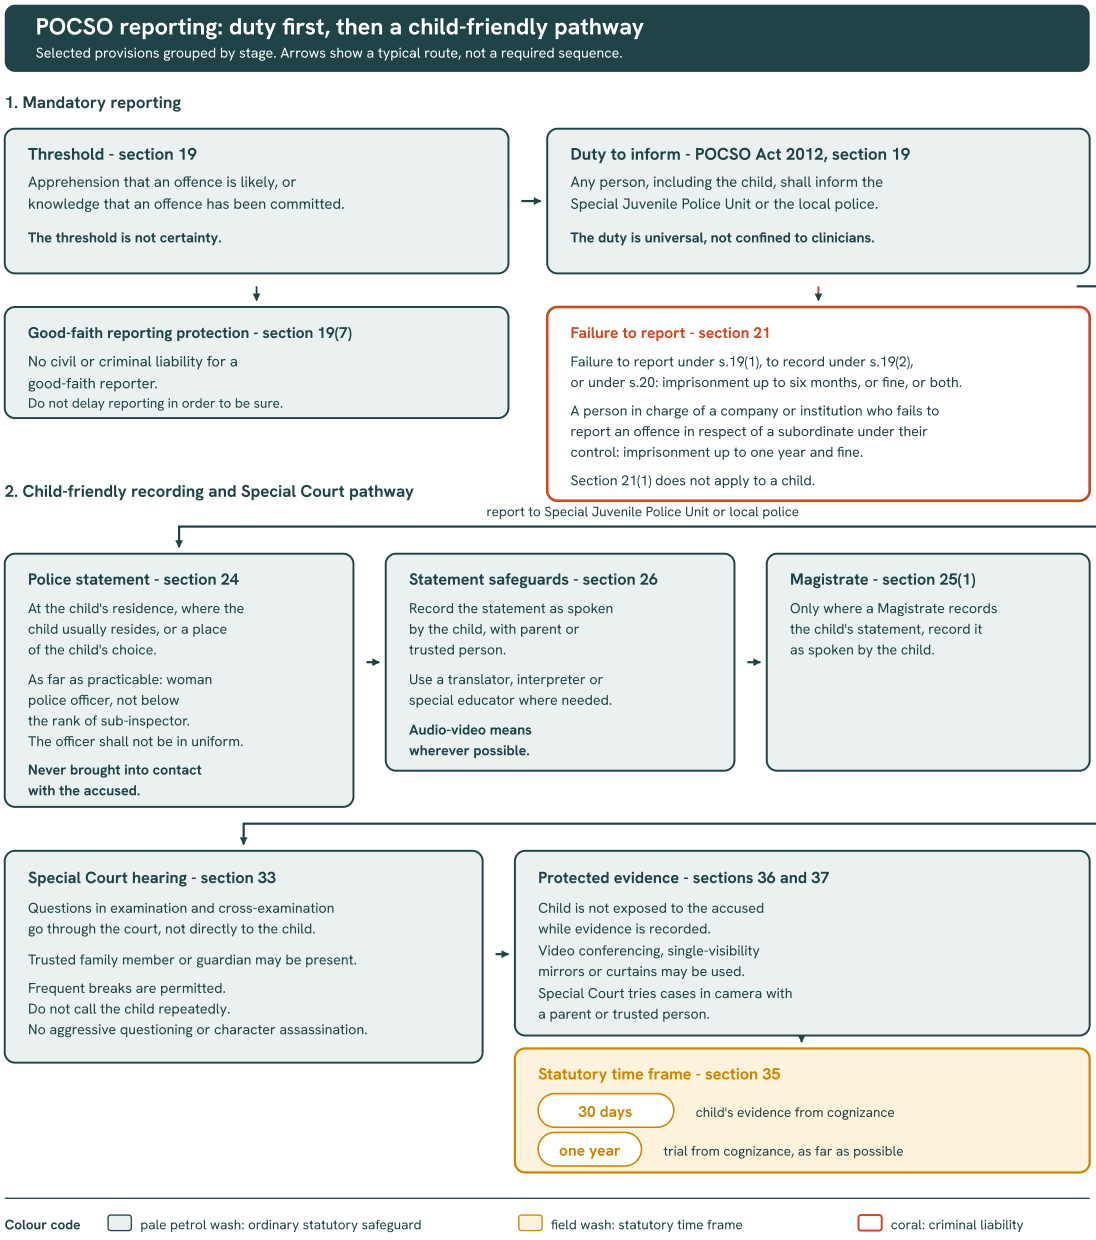

Fig 24.13. POCSO reporting is triggered by apprehension or knowledge, not certainty, and applies to any person including the child. After information reaches the Special Juvenile Police Unit or local police, the statute requires child-friendly recording and a protected Special Court pathway.

31.1 The reporting duty: threshold, person and destination

Mandatory reporting is often wrongly remembered as a duty that starts only after a clinician has reached diagnostic or forensic certainty. That is not the statutory structure. **Any person**, including the child, who has apprehension that an offence is likely or knowledge that one has occurred must provide the information to the **Special Juvenile Police Unit or the local police**. The threshold is thus framed around apprehension or knowledge, rather than a private conclusion that the allegation has been proved.

RULE **Under POCSO, report at apprehension or knowledge; do not wait for certainty.** The legal question is whether information has brought the statutory duty into operation, not whether the psychiatrist can resolve every inconsistency, establish intent, or predict the result of a future trial.

This distinction has practical force. Children may speak indirectly, may use developmentally idiosyncratic language, or may reveal information in fragments. Adults around them may be uncertain, distressed, defensive, or divided about what has occurred. None of those features gives the clinician a licence to convert the statutory threshold into a requirement for proof. Conversely, reporting is not a declaration that an accused person is guilty. It is the act that enables the legally constituted process to receive information and determine what follows. Keeping those two ideas separate protects both clinical thinking and legal compliance.

The duty is universal. A psychiatrist is not exempt because the information arose in a consultation, because the child is reluctant to speak further, or because a family member asks that the matter be kept private. Professional confidentiality remains important in ordinary care, but it cannot be used to erase a statutory reporting obligation. The therapeutic task is to communicate honestly and calmly about the limits of secrecy, without making promises that the law will not permit the clinician to keep. That stance preserves trust better than later disclosure that the clinician had silently made an assurance that could not be honoured.

IN INDIA

The statutory destination is specific: information goes to the **Special Juvenile Police Unit** or local police. The Act does not make the psychiatrist the final arbiter of whether an offence has been established. A good-faith reporter has statutory protection from civil or criminal liability, reinforcing why hesitation while seeking certainty is the wrong legal frame.

There is a useful distinction between *clinical ambiguity* and *legal inaction*. Clinical ambiguity may appropriately remain in a formulation: the psychiatrist may not yet know the meaning, reliability, context, or consequences of the information. Legal inaction is different when the reportable threshold has been reached. Candidates should be able to say that the Act makes room for uncertainty in the facts while refusing to make certainty a precondition for passing information to the designated authority.

- Do not convert the reporting threshold into a requirement for corroboration.
- Do not treat a child's reluctance to continue talking as a reason to promise secrecy.
- Do not treat reporting as a clinical finding of guilt or as a substitute for treatment.
- Do not confuse a lawful report with a licence for indiscriminate discussion of the child's account.

31.2 Failure to report: a statutory offence, not an ethical lapse alone

The legal character of the duty is made plain by the provision on **failure to report**. Failure to report or record the relevant information is itself a punishable offence. For a person who fails in

this duty, the Act provides imprisonment that may extend to **six months**, or fine, or both. The point for clinical practice is direct: a delayed report cannot be defended merely by saying that the clinician was still trying to become sure.

The Act also distinguishes institutional responsibility. A person in charge of a company or institution who fails to report an offence in respect of a subordinate under their control carries a more serious statutory exposure, with imprisonment that may extend to **one year** and fine. The first of those offences, the failure to report or to record, does not apply to a child. The exemption is written against that offence alone rather than against the section as a whole. The heightened exposure is confined to that supervisory relationship, but it remains relevant in hospital, school, residential, and child-care settings, where uncertainty about who should act can become a mechanism of delay. The individual clinician's responsibility does not disappear into a committee, hierarchy, or internal inquiry.

TRAP **"I need to be certain before I report" is the classic wrong answer.** It imports a proof standard that the reporting provision does not require. The Act places the decision about proof within the legal process, while making non-reporting a punishable omission.

The statutory offence should not be taught as a threat alone. Its purpose is to prevent a child's access to protection from depending on an adult's confidence, personal relationship with the family, or fear of being mistaken. It also makes clear why an institution should not use a private fact-finding exercise as a holding pattern. Internal processes may have their own legitimate purpose, but they cannot be allowed to displace the reporting route required by the Act.

In India, **mandatory reporting** under POCSO is a legal duty: any person with apprehension or knowledge must inform the designated police authority, and failure to report is punishable.

31.3 Child-friendly investigation: preserving the child's account

The reporting duty is only the entry point. The Act attempts to prevent the investigation itself from becoming a further source of injury by requiring a **child-friendly investigation**. A child's police statement is to be recorded at the child's residence, at the place where the child usually resides, or at another place chosen by the child. As far as practicable, it is recorded by a woman police officer of the required rank. Separately, and without that qualification, the recording officer must not be in uniform. The child must not be brought into contact with the accused during examination.

Each element has a clinical logic. A familiar or chosen setting may reduce the sense that the child is being taken into an adult-controlled system. The absence of uniform reduces the symbolic pressure of formal policing. Separation from the accused protects against fear, intimidation, and the contamination of the child's ability to speak. These are not therapeutic techniques, and they do not guarantee that the child will be comfortable. They are procedural safeguards that reduce avoidable pressure at a point when the child may be highly vulnerable.

For the psychiatrist, the important conceptual boundary is that the legal statement belongs to the legal process. A consultation may contain clinically relevant material, but the psychiatrist should not try to create a substitute forensic record by repeatedly testing the child's narrative, seeking a polished chronology, or forcing the child to rehearse details for adult reassurance. The child's welfare remains central, but the statute has assigned the formal recording function to specified officials using specified safeguards. The forensic and psychiatric assessment of child sexual abuse is addressed in the chapter section on child sexual abuse assessment and psychiatric sequelae.

PROCEDURAL POINT	STATUTORY SAFEGUARD	WHY IT MATTERS
Threshold for information	**Apprehension or knowledge**	Reporting does not await private proof.
Receiving authority	**Special Juvenile Police Unit or local police**	The statute identifies a formal destination.
Setting for the police statement	**Place chosen by the child**	Procedure is adapted to the child rather than institutional convenience.
Form of the record	**As spoken by the child**	The record should preserve the child's own expression.
Protection from confrontation	**No exposure to the accused**	Evidence can be obtained without compelled face-to-face contact.

Additional provisions protect the integrity of the child's words. The statement is recorded as spoken by the child in the presence of parents or another person in whom the child has trust or confidence. Where needed, a translator, interpreter, or special educator is to be provided, and audio-video recording is to be used wherever possible. These are not mere courtesies to be extended when a system has spare capacity. They recognise that communication access, language, developmental needs, and trust affect whether a child can participate meaningfully.

The same emphasis applies to the magisterial statement. Where the child's statement is recorded by a Magistrate under the current criminal procedure code, the protective requirement is that it be recorded as spoken by the child. The essential teaching point is the safeguard itself, not a recital of general criminal procedure. A psychiatrist who understands this can recognise why the legal process should not replace a child's words with an adult's interpretation, even when that adult is well intentioned.

GOOD TO REMEMBER

The phrase **as spoken by the child** is a safeguard against adult paraphrase. A child may need support to communicate, but support must not become substitution of the adult's language, meaning, or theory for the child's account.

The focus on trusted presence is also nuanced. A parent or trusted adult may help the child feel sufficiently safe to participate, but the statute does not turn that adult into the author of the account. In a clinical setting this distinction is valuable: adult distress, anger, fear, or a need for

immediate certainty can easily dominate the encounter. The child-friendly framework returns attention to the child's voice, communication needs, and protection from avoidable exposure.

31.4 Special Court procedure: evidence without intimidation

The Act carries the same protective logic into the **Special Court**. In examination and cross-examination, counsel communicates questions to the court, and the court puts them to the child. A family member, guardian, or another trusted person may be present. The court may permit frequent breaks, should avoid recalling the child repeatedly, and must not allow aggressive questioning or character assassination.

This does not mean that the child's evidence is insulated from scrutiny. Rather, scrutiny is structured so that the adversarial contest does not itself overwhelm the child. Direct confrontation by an adult advocate may be frightening or confusing even when the words used are technically permissible. Court mediation provides a protective filter: it does not predetermine the answer, but it places responsibility for the manner of questioning with the tribunal that has a duty to protect the child's participation.

The provision also helps candidates articulate why a child-friendly court process serves justice rather than competing with it. A child who is exhausted, terrified, humiliated, or repeatedly summoned may be less able to give a coherent account. Fair process is not achieved by maximising distress. It is achieved by allowing relevant questions to be put in a manner that preserves the possibility of reliable participation while respecting the procedural position of the accused.

- Questions reach the child through the court rather than directly from counsel.
- A trusted person may be present while the child gives evidence.
- Breaks may be permitted when the child needs them.
- The child should not be repeatedly called merely because adults have not organised the process well.
- Hostile questioning and attacks on character are not permitted.

A psychiatric report, when one is relevant to proceedings, should therefore be written with a clear understanding of role. It may assist the court on mental state, communication, or the impact of procedures, but it does not authorise the psychiatrist to decide the legal issue. Plain language, careful distinction between observation and inference, and fidelity to the child's actual communication are especially important where the report may become part of a process intended to minimise further harm.

> **PITFALL**
>
> Do not describe the protective procedure as though it prevents testing of evidence. The safeguard is that the **Special Court** mediates questions and controls the manner of participation, not that relevant questions disappear from the process.

31.5 Time, visibility and privacy during evidence

Delay can extend the burden on a child witness, particularly when the child remains uncertain about repeated attendance, future questioning, or possible contact with the accused. The Act therefore states that the child's evidence should be recorded within **thirty days** after the Special Court takes cognizance, with reasons recorded if there is delay. It further provides that the trial should be completed, as far as possible, within **one year** from cognizance. These are procedural commitments to reduce avoidable prolongation, not a reason for clinical care to become rushed or superficial.

THRESHOLD	EVIDENCE	TRIAL	HEARING
APPREHENSION OR KNOWLEDGE	WITHIN THIRTY DAYS	AS FAR AS POSSIBLE WITHIN ONE YEAR	IN CAMERA

The child must also be protected from seeing the accused while evidence is recorded, while the accused remains able to hear the child and communicate with counsel. The statute permits methods such as video conferencing, single-visibility mirrors, or curtains to achieve that balance. The educational point is not to memorise technology as a checklist. It is to understand the paired commitments: the child is protected from direct exposure, while the process retains the features needed for a fair hearing.

Finally, cases are tried **in camera**, in the presence of the child's parents or another person in whom the child has trust or confidence. Where the court is of the opinion that the child needs to be examined at a place other than the court, it shall issue a commission for that purpose. Privacy here is part of the architecture of participation. It limits unnecessary public exposure while allowing the court to obtain evidence in a setting more responsive to the child's needs.

The psychiatrist's role is to understand these protections well enough not to create false expectations. It is reasonable to explain that the legal system contains child-sensitive safeguards; it is not appropriate to promise a particular procedural outcome or to present a clinical opinion as a direction to the court. Honest explanation lowers anxiety without blurring the boundary between care and adjudication.

31.6 An integrated way to answer and practise the statute

A strong short answer begins with the legal duty, not with a catalogue of offences. State that mandatory reporting applies to any person with apprehension or knowledge, identify the Special Juvenile Police Unit or local police as the destination, and state that failure to report is punishable. Then show that the Act is child-friendly throughout its procedure: the statement is taken in a child-sensitive setting, preserved in the child's words with communication support where necessary, and followed by protective Special Court arrangements.

The deeper clinical lesson is one of disciplined role boundaries. Psychiatry contributes careful listening, humane communication, assessment of the child's mental state and needs, and treatment within its proper remit. The statute supplies a reporting obligation and a protected legal pathway. Neither role should swallow the other. When a clinician mistakes private uncertainty for permission to delay, the child may lose access to the statutory process. When a

clinician mistakes reporting for proof, the family may be misled about what a report means. When a clinician tries to become investigator, therapist, and adjudicator at once, the child's account may be burdened by adult needs rather than supported by a structured system.

For this reason, the provisions are best remembered as an ethic expressed in law: act when the threshold is met; preserve the child's voice; minimise coercive contact and repetition; protect the child in court; and maintain fairness without demanding that the child carry the full weight of an adult adversarial process. That is why this statute belongs in child psychiatry. It tells the clinician not only that protection is required, but also what a child-sensitive public response is meant to look like.

32 · Management and intervention in child abuse cases

Management begins by changing the question. Once abuse is disclosed or suspected, the immediate clinical task is not to obtain a fuller narrative for its own sake. It is to help the child move from exposure and uncertainty toward protection, care and a pathway that can be sustained. The psychiatrist brings a particular contribution: a calm, developmentally sensitive therapeutic stance, attention to safety, formulation of the child's current distress, and coordination with the adults and services that must act around the child.

These cases attract marks because they test clinical priorities rather than recall alone. A good answer separates the response to danger from the assessment of symptoms, separates treatment from investigation, and recognises that protection cannot be delivered by one professional in isolation. The detailed forensic assessment belongs with child sexual abuse assessment and psychiatric sequelae, and the statutory reporting duty and procedures belong with the POCSO Act. This section addresses the clinical response that follows recognition: **safety planning**, coordinated care, and trauma-focused intervention when it is indicated.

SAFE	TEAM	TRAUMA
PROTECT BEFORE PROCEEDING	COORDINATE THE RESPONSE	TREAT THE CURRENT NEED

32.1 The management frame: protect, organise, treat

The clinical response has several linked tasks, but they should not be confused.

- **Protection** asks whether the child can be kept safe while the next steps are arranged.
- **Organisation** asks who must communicate, who will remain a reliable therapeutic contact, and how the child will not be passed from room to room without explanation.
- **Treatment** asks what the child is experiencing now and what help is appropriate.

These tasks overlap, yet they have different purposes. Confusion between them produces a common failure: the clinician becomes absorbed in reconstructing events while the child's immediate environment remains unsafe or the family has no clear plan.

Safety is not an administrative prelude to mental health care. It is the condition that makes mental health care possible. A child who expects renewed exposure, retaliation, disbelief or chaotic handovers may be unable to use a therapeutic relationship freely. Conversely, a plan that

is formally protective but incomprehensible to the child can itself heighten fear. The clinician should therefore work in language the child can understand, avoid promises that cannot be honoured, and explain the next step before moving to it. The child does not need to carry responsibility for adult decisions; the child does need a coherent explanation of what is being done to help.

RULE **In an abuse response, safety planning comes before diagnostic neatness.** The working formulation can evolve, but the clinical encounter should immediately reduce avoidable danger, confusion and exposure.

A useful mental model is to ask, at every handover, whether the next action increases protection, preserves the child's sense of control, or makes later care easier to deliver. If it does none of these, it deserves scrutiny. This does not mean that care is passive or that difficult decisions are postponed. It means that the clinician distinguishes necessary action from hurried action, and uses the least disruptive route consistent with the child's safety.

32.2 Safety planning as an active clinical intervention

Safety planning is an active, child-centred process rather than a note stating that somebody else will manage risk. The immediate plan should make clear:

- where the child will be and which adults can be relied upon;
- how contact with a suspected source of harm will be prevented while protection arrangements are considered; and
- whom the child can approach if fear or pressure returns.

Its content must remain responsive to the child's circumstances and to the capacities of the adults around them. A plan that assumes a supportive adult without examining whether that adult can actually protect is fragile.

WHO's guidance places action to enhance safety and reduce harms associated with disclosure among the **first-line** clinical responsibilities in responding to child sexual abuse. This includes attention to **visual and auditory privacy**. Privacy is practical as well as relational: conversations should not be audible to people who have no clinical role, the child should not be made to repeat sensitive material in public spaces, and the setting should not permit a potentially unsafe person to control the exchange. These small features communicate whether the service understands the child as a person needing protection rather than as a source of information.

Safety planning should be revisited when circumstances change. A plan may look adequate during a supervised clinical contact and fail during transport, school attendance, family visits, or communication between adults. The psychiatrist need not personally control every setting in which the child lives. The responsibility is to make safety a visible clinical priority, identify uncertainty clearly, and ensure that the relevant protection pathway is activated rather than assumed. When the child's account and an adult's account differ, the child should not be asked to resolve the discrepancy by further exposure or confrontation.

GOOD TO REMEMBER

Ask the child what would make the next few hours and the next contact feel safer. The answer may reveal a practical risk that is invisible in a formal record, such as fear of a particular handover, a place in the home, or being left alone with a particular adult.

The clinician's language matters. It is helpful to validate that the child has done the right thing in seeking help without making the child responsible for proving anything. It is equally important not to create false reassurance. Statements such as "nothing will happen without your permission" may be untrue where protective action is required. A more trustworthy stance is to say that the adults will explain what has to happen, will try to involve the child in a way that feels manageable, and will continue to care even if the process is difficult.

32.3 Preserve the therapeutic space without duplicating the forensic task

The management consultation is neither an interrogation nor a substitute for the safeguarding-specific evaluation. The detailed assessment of child sexual abuse, including its psychiatric sequelae, is addressed in the section on child sexual abuse assessment and psychiatric sequelae. Here, the psychiatrist's task is to listen sufficiently to understand current safety and distress, then to organise care without turning each review into a demand for a more elaborate account. Repeated, uncoordinated retelling can leave the child feeling disbelieved, observed or responsible for the adult process.

A therapeutic conversation can therefore remain focused on immediate experience: what the child is afraid of now, whether sleep, concentration, mood, bodily distress or relationships have changed, and what support feels possible. The clinician can record what is clinically necessary in a clear, restrained way and avoid interpretive excess. When uncertainty is present, it should be documented as uncertainty. The discipline of saying "not yet known" is clinically safer than filling a gap with assumptions, whether those assumptions minimise harm or enlarge it.

TRAP **Do not mistake a compassionate clinical interview for a licence to conduct a fresh forensic inquiry.** The urge to obtain a complete story can crowd out safety, fragment the response, and blur the psychiatrist's therapeutic role.

There is a second reason to preserve role clarity. The child may need the psychiatrist over time, after external processes have moved on. If the child experiences the clinician primarily as another adult collecting an account, later work on fear, trust, shame, anger or relationships may be harder to establish. A reliable therapeutic stance is not neutral about harm. It is clear that the child deserves protection, while remaining careful about the limits of what the clinician knows and what the current consultation is for.

Families may also press the psychiatrist to decide who is telling the truth, to arbitrate a conflict, or to certify that no further action is needed. Such requests should be recognised as pressure on the clinical frame. The psychiatrist can acknowledge the family's anxiety and return to the child's welfare: safety concerns require a coordinated response, and symptom care requires a relationship in which the child is not made to manage adult disagreement.

32.4 Coordinated multidisciplinary management

Abuse cases commonly demand **multidisciplinary management**. The value of a team is not merely that several professionals are involved. It is that their tasks are made complementary. A coherent team can reduce contradictory messages, prevent unnecessary repetition, arrange the right referral at the right time, and keep the child's clinical needs visible while other processes unfold. A collection of professionals acting independently is not yet a team.

Structured clinical practice guidance can support complex work by **multidisciplinary teams**. In practice, the psychiatrist should establish a shared formulation of the immediate problem, identify the person responsible for coordinating communication, and clarify what information needs to travel with the child and what should not be casually circulated. Coordination is especially important when the child's home, school, clinical setting and protection pathway give different adults partial pictures of the situation. A shared plan should make these partial views usable without making the child retell the same distressing material to every service.

CLINICAL QUESTION	PURPOSE OF COORDINATED ACTION	PSYCHIATRIST'S CONTRIBUTION
Is the child safe for the next step?	Make protection explicit rather than assumed.	Keep safety planning central to the formulation.
Who needs to act now?	Avoid diffusion of responsibility.	Communicate the clinical concern and identify the needed links.
What should the child be told?	Reduce uncertainty and preserve trust.	Use developmentally understandable explanations.
What needs follow-up?	Prevent care ending after the first crisis.	Review distress, functioning and the safety plan.

Teamwork should not erase confidentiality. Information sharing should be purposeful and limited to what is needed for protection and care. The child and caregiver should be told, as far as possible, why information is being shared and what the next contact will involve. When a caregiver's interests conflict with the child's safety, the clinician's primary orientation remains the child's welfare. This is not hostility toward the family. It is the ethical discipline needed when the family system cannot be presumed to be a safe container.

IN INDIA

Management in India must join the clinical plan to the child-protection and legal pathway rather than treating psychiatric care as a parallel, private service. The statutory duties and child-friendly procedures are set out in the POCSO Act section; the psychiatrist's role here is to ensure that safety, communication and continuing care do not disappear while those processes are being activated.

32.5 Formulation after abuse: treat the child in front of you

Protection and treatment are related but not interchangeable. Removing an immediate source of danger may reduce distress, but it does not automatically restore sleep, trust, concentration, affect

regulation or a sense of bodily safety. Equally, beginning psychological work without attending to ongoing exposure asks therapy to compensate for an environment that remains unsafe. The psychiatrist should formulate the child's present difficulties in context: the meaning the child gives to what happened, the current relational environment, the responses of important adults, and the practical conditions under which treatment will occur.

Formulation protects against two opposite errors. One is to see every reaction as evidence of a psychiatric disorder and to medicalise an understandable response to danger. The other is to assume that distress is simply transient because it follows a known stressor. The child may need support even when a formal diagnosis is not the immediate clinical question, and may need more focused treatment when symptoms are persistent, impairing or organised around traumatic reminders. The clinician should follow change over time without requiring the child to demonstrate suffering in a particular way.

Caregiver work is often central to the formulation. An adult who can believe, protect and remain emotionally available can help the child recover a sense that relationships can be safe. An adult who is overwhelmed, disbelieving, dependent on a suspected source of harm, or preoccupied with blame may require support and careful boundary-setting before being treated as a therapeutic resource. This is why involvement of family cannot be automatic. The relevant question is whether a particular adult can safely contribute to the child's care.

PITFALL

Do not treat the presence of a caregiver as proof of protection. The clinically relevant issue is whether that adult can reliably support the child without exposing the child to pressure, disbelief, divided loyalty or renewed risk.

32.6 Trauma-focused psychological intervention

For children and adolescents who have been sexually abused and are experiencing symptoms of PTSD, WHO recommends that **trauma-focused CBT** be considered. The wording matters. It points to a focused psychological intervention for a defined clinical presentation, not to a generic requirement that every child who discloses abuse should be placed into the same therapy immediately. The psychiatrist should connect the intervention to the child's current symptoms, readiness, safety and ability to attend, rather than treating a therapy label as a complete formulation.

Trauma-focused work is organised around helping the child approach distress in a planned, tolerable way rather than leaving reminders to govern the child's life. It requires a therapeutic relationship in which the child has enough predictability to engage and enough choice to communicate limits. The work should neither compel disclosure on the clinician's timetable nor collude with complete avoidance of the child's experience. Its clinical value lies in giving experience a form that can be thought about, linked to present safety, and integrated without defining the child's identity.

Psychiatric review remains important during psychological treatment. Symptoms may change as memories, fears and family tensions become more discussable. The psychiatrist monitors whether the treatment setting continues to feel safe, whether the child is becoming more isolated or pressured outside therapy, and whether additional support is needed around functioning and relationships. This is not a reason to fragment care by adding multiple unrelated interventions. It is a reason to keep a coherent formulation alive while treatment proceeds.

When trauma-focused CBT is being considered, the explanation to the child should be plain: the work is intended to reduce the hold that frightening memories and reminders have on present life. Children should not be told that they must revisit everything at once, nor should they be led to believe that recovery depends on producing a particular account. A respectful explanation protects engagement and makes it less likely that therapy will resemble another process imposed by adults.

32.7 Involving the non-offending caregiver

WHO further advises considering **trauma-focused CBT for the child and non-offending caregiver** when it is safe and appropriate to involve that caregiver. The intervention is for **both** child and caregiver, rather than treating family participation as an optional afterthought. It recognises that the caregiver's emotional response, protective capacity and understanding of the child's distress can shape the child's treatment environment. Caregiver involvement can help the adult respond more steadily to fear, anger, withdrawal or reassurance-seeking without making the child responsible for the adult's emotions.

"Non-offending" should not be treated as a sentimental label. It names a clinical and safeguarding question: can this adult participate without compromising the child's safety or making therapy unsafe? The answer may differ across caregivers and may change with circumstances. The clinician should avoid inviting an adult into the therapy space simply because that adult is available, socially expected to participate, or distressed by exclusion. Involvement is justified by the child's welfare, not by adult entitlement.

Caregiver sessions can create room for the adult's confusion, guilt, anger or grief while keeping the child free from having to regulate those reactions. They can also clarify what supportive responses look like in everyday life: believing the child without demanding repeated details, protecting routines where possible, and keeping conflict away from the child. If the caregiver cannot safely take this role, the team must not pretend otherwise. A stable therapeutic frame is more valuable than nominal family participation.

MNEMONIC

SAFE TEAM TRAUMA

Safe environment first, a coordinated **team** around the child, then **trauma**-focused work when the child's presentation calls for it. The phrase is a sequence of clinical priorities, not a substitute for formulation.

32.8 Continuity, review and the endpoint of care

Continuity is a therapeutic intervention in its own right. Abuse may leave the child expecting adults to become unavailable, disbelieving or preoccupied with procedure. A service that offers one sympathetic consultation and then disappears can unintentionally repeat that experience. Follow-up should therefore review safety, the child's experience of the plan, current distress, the availability of a protective adult, and whether the various parts of the response are still communicating. The question is not simply whether symptoms have reduced. It is whether the child now has enough safety and support to resume development without being defined by the abuse response.

Ending care should be planned, not allowed to occur by default after the crisis has quietened. The child and supportive adults should understand what has improved, what difficulties may recur, and how to seek help again without having to reconstruct the entire story. A clear ending acknowledges recovery while leaving the door open to return. It also prevents the false binary in which the child is imagined as either permanently damaged or completely unaffected.

For the psychiatrist, the enduring discipline is to resist both rescue fantasy and procedural detachment. One clinician cannot repair every consequence of abuse, but can ensure that psychiatric care adds safety, clarity and a sustained therapeutic relationship to the wider response. That is the practical meaning of child-centred management.

> In child abuse management, protect the child first, coordinate the adults and services around the child, and use trauma-focused intervention for the child's current clinical needs.

33 · Juvenile Justice (Care and Protection of Children) Act 2015

Why it matters clinically. The **Juvenile Justice (Care and Protection of Children) Act** 2015 is not a diagnosis framework or a substitute for child psychiatric formulation. It decides which authority receives a child, what question that authority must answer, and when a psychiatrist may assist. It prevents an alleged act by a child from obscuring vulnerability, and vulnerability from being mistaken for criminality. For legal wording, read the primary Act rather than a paraphrase.

The safest way to learn the Act is through its offence route and protection route. They can meet in the same child, but begin with different questions and are handled by different statutory bodies. Identify the route before naming the forum.

ACT	VULNERABILITY	BOARD	COMMITTEE
ALLEGED OFFENCE BY THE CHILD	NEED FOR CARE AND PROTECTION	FORUM FOR THE OFFENCE ROUTE	FORUM FOR THE PROTECTION ROUTE

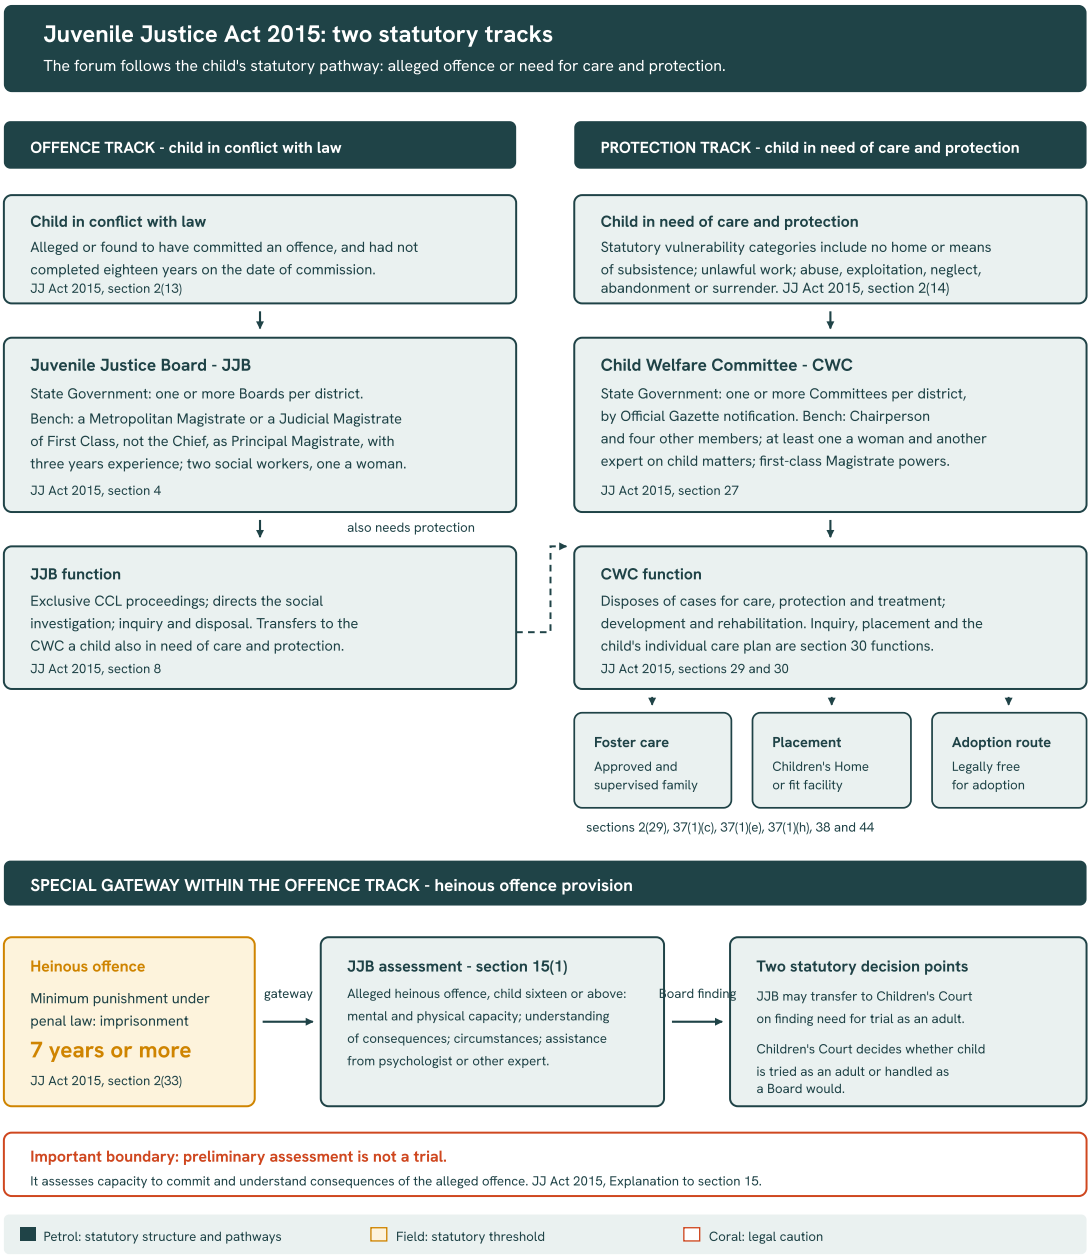

Fig 24.14. The JJ Act 2015 separates the offence-based CCL pathway governed by the JJB from the vulnerability-based CNCP pathway governed by the CWC. Heinous-offence assessment is a capacity assessment by the Board, with a separate subsequent decision by the Children's Court.

33.1 The statutory map: act, vulnerability and forum

A **child in conflict with law** is a child alleged or found to have committed an offence, provided the child had not completed **eighteen** years on the date of the alleged offence. The date of the act, rather than the date of apprehension or hearing, is therefore the legally relevant anchor. This is a narrow, offence-based description. It does not tell the clinician whether the child is distressed, impaired, exploited, traumatised, or unsafe. Those are clinical and protective questions that still need attention.

By contrast, a **child in need of care and protection** is identified by vulnerability. The statutory categories include a child without a home or apparent means of subsistence, a child working

contrary to labour law, and a child who has been abused, exploited, neglected, abandoned or surrendered. The practical distinction is morally important. On the offence route, the system asks what the child is alleged to have done. On the protection route, it asks what danger, deprivation or failure of care has happened to the child.

QUESTION THAT STARTS THE ROUTE	STATUTORY TRACK	PRIMARY FORUM	CLINICAL IMPLICATION
Is the child alleged to have committed an offence?	Child in conflict with law	Juvenile Justice Board	Keep developmental and welfare needs visible during the inquiry.
Is the child exposed to a statutory form of vulnerability or unsafe care?	Child in need of care and protection	Child Welfare Committee	Frame the problem as protection, treatment and rehabilitation, not misconduct.
Does the same child meet both descriptions?	Overlapping need	Board with transfer to Committee where required	Do not allow one label to erase the other route.

RULE **Classify the child by the legal question before discussing the psychiatric opinion.** The Act separates alleged offending from need for protection, and it gives each route a distinct decision-making body.

These labels should not become clinical identities. Anger, withdrawal, substance use, developmental limitations, fear or apparent indifference do not alone determine the statutory track. Conversely, a child alleged to have offended may also need immediate safety planning. The Board can transfer a child in conflict with law to the Committee when the child is also in need of care and protection. This seam allows care needs to be addressed without denying the allegation.

33.2 Juvenile Justice Board: the offence-route authority

The **Juvenile Justice Board** is constituted by the State Government for each district and is a Bench, rather than a lone magistrate making an administrative referral. Its Principal Magistrate is a Metropolitan Magistrate or Judicial Magistrate of the first class, not being a Chief Metropolitan Magistrate or Chief Judicial Magistrate, with at least **three years** of experience. The statutory composition also includes social workers, with a woman member required. The point of this design is not ceremonial. It brings judicial authority and child-welfare expertise into the same decision-making structure.

The Board deals exclusively with proceedings concerning children in conflict with law within its district. It directs the Probation Officer, or where a Probation Officer is not available the Child Welfare Officer or a social worker, to undertake the social investigation and report within **fifteen days** of first production. It conducts the inquiry, disposes of cases, and can transfer to the Child Welfare Committee a child who also requires care and protection. A psychiatrist should therefore understand that a report may inform the Board's work, but does not replace its inquiry or decide the case. The clinical task is bounded by the question put to the expert and by the child's developmental context.

GOOD TO REMEMBER

When a referral comes through the offence route, write the referral question at the top of the assessment. Separate observed symptoms, developmental functioning, the child's account, collateral information and limits of inference. This keeps a clinical opinion useful without allowing it to drift into a judicial conclusion.

For the psychiatrist, the Board is often the point at which a child's mental health needs become legible to the justice system. That does not make the psychiatrist a prosecutor, defence witness, or final arbiter of legal responsibility. It makes the psychiatrist a clinician who can describe relevant capacities and vulnerabilities with precision, including what the available information can and cannot support. Neutrality is especially important where family pressure, institutional narratives, or the seriousness of an allegation makes a quick explanatory label tempting.

33.3 Child Welfare Committee: the protection-route authority

The **Child Welfare Committee** is the statutory authority for the protection route. It is constituted for each district by State Government notification and functions as a Bench with magisterial powers. It consists of a Chairperson and **four** other members, including a woman member and a member with expertise in child matters. Its orders are not merely recommendations: its legal authority is what permits a protective plan to become an operative placement or care decision.

The Committee has authority to dispose of cases concerning care, protection, treatment, development and rehabilitation of children in need of care and protection. It may conduct inquiry and make placement decisions in relation to the child's **individual care plan**. The phrase matters clinically. The child's psychiatric needs are part of the care problem, but they should be considered alongside safety, attachment, family capacity, educational continuity and the feasibility of the proposed setting. A diagnosis alone cannot answer whether a placement is protective or sustainable.

IN INDIA

The Board and the Child Welfare Committee are statutory Indian forums, not informal multidisciplinary meetings. In a referral letter, name the route clearly and state whether the child's presentation raises protection needs in addition to the immediate clinical question. This makes it harder for a vulnerable child to be passed between services with nobody owning the protective decision.

The Committee's remit also corrects a clinical blind spot. A child who has been neglected or exploited may present with disruptive behaviour, school refusal, self-harm, dissociation, substance use, somatic complaints, or a flat account of serious adversity. The clinical formulation must not convert this into an account of individual pathology alone. The statutory route requires attention to the environment that is failing the child. Detailed recognition and management of abuse are addressed in the child-protection sections of this chapter; here, the essential point is

that vulnerability can activate a protection process even when no offence is alleged against the child.

33.4 When both routes are present

The two tracks are distinct, not mutually exclusive. A child may be alleged to have committed an offence while also being homeless, exploited, abused, neglected, abandoned, or otherwise unsafe. The Board's transfer power to the Committee is the statutory answer to this overlap. In clinical language, the allegation must not eclipse the formulation, and the formulation must not erase the allegation. Both statements can be true, and the system has a route for both.

> **TRAP** **Do not treat "conflict with law" as the opposite of "in need of care and protection."** The first phrase describes an alleged offence; the second describes vulnerability. A child can fall within both descriptions, so a protection concern must be surfaced even during offence-route proceedings.

This is where psychiatric language can either help or harm. Descriptions such as conduct problems, impulsivity, intoxication, trauma symptoms, intellectual limitations, or family conflict should be used to illuminate the child's situation, not to shortcut the statutory analysis. The clinician should state what has been observed, what has been reported, whose account is being relied upon, and whether the available material supports an opinion on the question asked. A report that becomes a broad moral explanation for the allegation is both clinically weak and legally unhelpful.

33.5 Heinous offences and the preliminary assessment

A **heinous offence** is defined by the minimum punishment prescribed in the penal law: imprisonment of **seven years** or more. This statutory threshold is the gateway to the special preliminary-assessment process for an older child within the Act's definition of childhood. It is a legal classification of the alleged offence. It is not a psychiatric diagnosis, an index of dangerousness, or a conclusion about the child's maturity.

For a heinous offence alleged against a child who has completed or is above **sixteen** years, the Board conducts a **preliminary assessment**. It considers the child's mental and physical capacity to commit the alleged offence, ability to understand its consequences, and the circumstances in which it is alleged to have occurred. The Board may take assistance from psychologists or other experts. The clinician's contribution is consequently evidence for a statutory assessment, not an independent decision to move the child into an adult process.

The legal formulation deliberately requires more than a label. A diagnosis, a screening score, an intelligence estimate, a history of adversity, or the apparent sophistication of one act cannot by itself answer the entire question. Capacity and understanding have to be considered in relation to the alleged conduct and its context. The assessment should therefore be careful about language, avoid conclusions that exceed the records and interview, and distinguish a clinical observation from an inference about the legal question.

MNEMONIC

Capacity - Consequences - Circumstances

For the preliminary assessment, organise the psychiatric contribution around the child's capacity in relation to the alleged act, understanding of consequences, and the circumstances in which the allegation arose. The Board remains the authority that assesses these matters with expert assistance.

PITFALL

Do not write a report as though the preliminary assessment were an insanity opinion. The statutory question is developmental capacity and understanding in relation to the alleged offence. A report that imports another legal test can obscure the exact issue the Board must decide.

33.6 What the preliminary assessment is not

The Act expressly states that this preliminary assessment is not a trial. This distinction has practical force. The clinician does not determine guilt, assess the evidentiary strength of the allegation, decide the final forum, or pronounce a general conclusion on criminal responsibility. The assessment addresses the limited statutory questions of the child's capacity to commit and to understand consequences of the alleged offence.

General criminal responsibility, the insanity doctrine, the current criminal-law provisions and adult forensic assessment belong in *the Mental health legislation and forensic psychiatry notes*. Cross-refer there rather than importing that doctrine into a juvenile preliminary assessment. The two inquiries can sound similar because both involve mental state and legal consequence, but they are not interchangeable. In an answer, saying that the preliminary assessment is not a trial and not a general criminal-responsibility determination earns clarity because it protects the statutory boundary.

Expert assistance does not make the expert the decision-maker. The Board conducts the assessment, may use psychological or other expert assistance, and retains the statutory role. A well-written psychiatric opinion is therefore disciplined: it identifies the clinical material, explains its relevance to the specified capacity or understanding question, and records uncertainty where the material does not permit a defensible inference. It should not mimic a judgment or use conclusory phrases that collapse assessment, culpability and disposal into one opinion.

33.7 Transfer and the second decision point

After the preliminary assessment, where the Board finds a need for **trial as an adult**, it may transfer the trial to the Children's Court. That transfer is not the endpoint. The Children's Court itself decides whether the child is to be tried as an adult or handled as the Board would handle the case. The Board's finding and the Court's decision are separate statutory steps.

STAGE	WHO ACTS	QUESTION ANSWERED	WHAT THE PSYCHIATRIST MUST NOT ASSUME
Preliminary assessment	Juvenile Justice Board, with expert assistance where used	Capacity, understanding of consequences and circumstances in the statutory setting	That expert input decides guilt or adult trial.
Transfer decision	Juvenile Justice Board	Whether transfer to the Children's Court is required after the assessment	That transfer itself converts the child into an adult defendant.
Post-transfer decision	Children's Court	Whether adult trial is appropriate or the matter should be handled as by the Board	That the Board's view is the final legal outcome.

This sequence is a frequent examination discrimination because the language of adult trial can lure the reader into collapsing the stages. It is also a clinical safeguard. The psychiatric assessment may be influential, but it does not erase the child's statutory status or collapse judicial functions into a medical opinion. In reports and oral evidence, keep the limited purpose of the opinion visible.

33.8 Protection decisions and continuity of care

For a child in need of care and protection, the Committee may make decisions that connect immediate safety with longer-term care. Its statutory options include placement in a Children's Home, fit facility or Specialised Adoption Agency, the last for the purpose of adoption, an order for **foster care**, and a declaration that a child is legally free for adoption. The legal content of adoption and the psychiatric aspects of child labour and adoption are addressed elsewhere; psychiatric care must remain connected to the placement decision.

Foster care means placement in the domestic setting of a selected, qualified, approved and supervised family other than the child's biological family. It is not simply an informal arrangement with any available household. When asked to advise, the psychiatrist does not select the placement, but can identify mental-health needs that should shape the care plan.

> The Juvenile Justice Act separates an alleged offence from a child's vulnerability, and a psychiatric opinion assists the statutory forum without replacing it.

33.9 A disciplined examination and clinical approach

In a short answer, proceed in a disciplined order:

- identify the offence route or the protection route;
- name the Board or Child Welfare Committee as the relevant forum;
- state that age on the date of the alleged offence anchors the offence-based definition;

- for the heinous-offence provision, describe capacity, understanding of consequences and circumstances, then state that the assessment is not a trial and the Children's Court decides after transfer.

In practice, the same sequence is a safeguard against role confusion. Identify the forum, obtain the precise referral question, preserve a developmental and trauma-informed formulation, state evidential limits, and flag protection concerns that may require the other route. Where the child is frightened, poorly understood, or embedded in an unsafe family or institutional context, the report should make those needs visible in clinically careful language. It should never offer a shortcut from symptom to culpability, or from allegation to a conclusion that the child has no claim to protection.

34 · Child in conflict with law and child in need of care and protection

Why this distinction matters clinically. A child may enter the juvenile justice system because of an alleged act, or because the child is unsafe, unsupported, exploited or without care. Those are not interchangeable descriptions, and they call for different clinical questions. The psychiatrist's first task is to avoid allowing the presenting label to flatten the child into either an offender or a passive victim. The useful formulation asks what has happened, what the child needs now, what relationships and environments are available, and what information the statutory process needs from mental-health care.

The marks in this area lie in making a clean discrimination before discussing intervention. The legal label supplies a pathway; it does not describe the whole child, establish a psychiatric diagnosis, or determine whether treatment is needed. Disorders, developmental variation and general criminal responsibility are addressed elsewhere. Here the focus is the distinction between an offence-based pathway and a protection-based pathway, and the practical meaning of protective placement for psychiatric work.

OFFENCE	VULNERABILITY	PLACEMENT
ALLEGED ACT PATHWAY	PROTECTION PATHWAY	CARE MAY NEED TO CHANGE

34.1 The distinction that prevents category error

A **child in conflict with law** is a child alleged or found to have committed an offence, provided the child had not completed **eighteen years** when the alleged offence was committed. The anchor is the time of the alleged act, rather than a later procedural event. This is not a diagnosis and it does not establish an explanation for the behaviour. A psychiatric opinion may help describe symptoms, developmental capacity, adversity, substance use, family context and treatment need, but it should not casually transform a legal label into a clinical conclusion.

By contrast, a **child in need of care and protection** enters the protection pathway because of vulnerability, not because the child is alleged to have done something. The statutory idea is deliberately broad. It can apply where a child lacks a stable home or visible means of subsistence, is found working contrary to labour law, or is abused, exploited, neglected, abandoned or surrendered. In clinical language, the question is not simply "what is wrong with the child?" It is

also "who is reliably keeping this child safe, and what setting can support recovery and continuity of care?"

RULE **Start with the pathway, then formulate the child.** The offence-based label is triggered by an alleged act; the protection label is triggered by vulnerability and unmet care. Neither should be treated as a psychiatric diagnosis or as a moral summary of the child.

CLINICAL QUESTION	CONFLICT-WITH-LAW PATHWAY	CARE-AND-PROTECTION PATHWAY
What brings the child into view?	An allegation or finding concerning an offence.	A concern that the child is vulnerable or lacks safe care.
What must not be assumed?	That the alleged act proves a disorder, intent or a fixed character.	That vulnerability means the child has no agency, preferences or strengths.
What is the immediate psychiatric task?	Describe current needs without replacing the legal process with a clinical opinion.	Clarify distress, safety, relationships and the supports needed for stable care.
What is the placement question?	Do not infer a placement answer from the label alone.	Match the care plan to safety, continuity and the child's developmental needs.

Child in conflict with law concerns an alleged act; child in need of care and protection concerns vulnerability and the need for safe care.

34.2 Why age anchoring and language matter

The age element is often tested because it forces attention to the correct clinical-legal timeline. Record the child's account, collateral history and available documentation with their source and degree of certainty. Do not silently substitute the date of assessment, apprehension, remand, referral or hearing for the legally relevant time point. Such substitution can make an otherwise careful report misleading. The treating team does not decide the legal issue by itself, but it must avoid producing imprecise prose that appears to decide it.

Language also changes what the team notices. "Delinquent," "criminal," "bad family," and similar shorthand can obscure trauma, coercion, learning difficulty, acute distress, disability, peer influence or unmet social needs. The converse error is equally important: compassion does not require excusing away all agency, and a psychosocial explanation is not a legal conclusion. The psychiatrist should use person-first, behaviour-specific language: what is reported, what is observed, what remains uncertain, and what treatment or environmental support is indicated.

TRAP **Do not decide status from the child's age at assessment.** The statutory definition fixes the relevant age at the time of the alleged offence. A later age belongs in the chronology, not in place of that anchor.

For general criminal responsibility, adult forensic assessment and the wider legal framework, see *the Mental health legislation and forensic psychiatry notes*. The present distinction is narrower. It

helps the clinician identify whether an alleged act is the doorway into the system, or whether the system is being asked to secure care for a child whose circumstances have become unsafe.

34.3 The psychiatrist's role: formulation without role confusion

When the referral concerns a child in conflict with law, the clinical report should answer the clinical question asked and stay within that scope. It should distinguish observed findings from reports by others, and acknowledge limits imposed by the setting, distress, language, separation from carers or incomplete collateral. A report gains authority by being precise about its boundaries, not by using legal language it cannot support. The general child psychiatric assessment framework is addressed elsewhere in this chapter; this context changes how its findings must be communicated, not the need for disciplined assessment.

When the referral concerns care and protection, clinical work is often inseparable from the experience of disruption. A child may have lost routines, separated from familiar adults, entered an unfamiliar setting, or had prior care marked by neglect or exploitation. Symptoms can be meaningful responses to uncertainty as well as evidence of a disorder. The formulation should therefore account for the child's felt safety, supportive relationships, ordinary routines, fears about change and practical barriers to treatment. This is not a separate forensic battery. It is good child psychiatry applied to a protection context.

The clinician should resist being recruited into a false binary. A child can require protection while also being involved in an alleged offence. Conversely, a child referred after an alleged offence may disclose violence, exploitation or absence of care. The point is not to assign a single identity. It is to ensure that a disclosed protection concern is not overlooked because the referral arrived through an offence-related doorway. The statutory route and the clinical formulation may interact, but they answer different questions.

> **GOOD TO REMEMBER**
>
> A useful report separates facts, the child's account, collateral information, clinical inferences and recommendations. That separation protects the child, makes uncertainty visible and prevents a treating opinion from masquerading as a legal finding.

34.4 Care planning and placement are clinical continuity issues

For a child in need of care and protection, a placement decision is not merely an address. It changes who can observe symptoms, bring the child to appointments, hold medication safely, support therapy attendance, understand triggers, and notice deterioration or improvement. The mental-health contribution is therefore practical: identify the supports that preserve safety and continuity, rather than making a vague recommendation for "rehabilitation." Recommendations should be tied to the child's current presentation and should state what information needs to travel with the child when care arrangements change.

The statutory options include **placement in a Children's Home, fit facility, or Specialised Adoption Agency**, the last of these for the purpose of adoption, for either temporary or longer-term care. These words identify possible care settings, not a hierarchy of emotional adequacy.

Any setting can be destabilising if a child's history, relationships and treatment requirements disappear at the point of transfer. Equally, a stable transition can be therapeutic even when a change of setting is unavoidable. The psychiatrist should communicate needs in a form that a receiving care team can use.

Before a change in care arrangements, the clinician should communicate:

- the child's current emotional and behavioural presentation, including any immediate safety concern;
- what tends to reduce distress and what predictably escalates it;
- the relationships, routines and communication supports that help engagement; and
- the practical plan for continuing medication, psychological work and follow-up.

IN INDIA

Use the statutory language accurately, but keep the clinical recommendation readable by the receiving service. A sentence that names the support needed, the reason it matters and the information that must accompany the child is more useful than a broad declaration that the child requires institutional care.

PITFALL

Do not let a transfer become an undocumented clinical reset. Repeating the full assessment is sometimes necessary, but loss of the prior formulation, current treatment plan and known calming supports can itself create avoidable distress and apparent non-engagement.

34.5 Foster care: an alternative family environment, not an informal arrangement

Foster care is alternate care in the domestic environment of a family other than the child's biological family, where that family has been selected, qualified, approved and supervised. This definition matters because it distinguishes statutory foster care from an informal arrangement with relatives, neighbours or acquaintances. The emotional quality of informal support may be important clinically, but it should not be inaccurately described as the statutory placement option.

For a child declared in need of care and protection, a **foster-care order** is a possible disposal pathway, made under **section 44**. The statutory process is covered in the chapter section on the Juvenile Justice Act. The psychiatrist's narrower responsibility is to help the care plan anticipate adjustment: how the child responds to unfamiliar adults, separations and limits; what supports foster carers will need to understand; and how treatment can continue without turning the foster setting into a clinic.

MNEMONIC

OVP - Offence, Vulnerability, Placement

Use this as a quick organising spine. Identify whether the system entry is an alleged offence or vulnerability, then ask what care arrangement will preserve safety and psychiatric continuity.

34.6 Adoption pathway and respectful clinical handover

A child in need of care and protection may be the subject of a declaration that the child is **legally free for adoption**. The declaration opens an adoption pathway; it is not a psychiatric prediction about attachment, future behaviour or the quality of a prospective family. Avoid language that pathologises the child because the child has experienced separation, institutional care or disruption. At the same time, do not conceal clinically relevant history that a future care plan needs in order to be safe and realistic.

Adoption law and assessment of adoptive-parent fitness are beyond this section. The psychiatric contribution is a careful, minimum-necessary handover: current symptoms and treatment, communication and learning needs, known trauma-related sensitivities where clinically relevant, protective routines, and follow-up needs. It should be written with awareness that records can affect a child's future relationships. Include what helps, not only what has gone wrong. Do not convert uncertain formulation into a permanent label.

The same discipline applies across all protective placements. Explain the child in a way that supports care, preserves dignity and keeps legal decisions in their proper forum. In practice, that is the bridge between child psychiatry and protection work: a report that is clinically useful, developmentally sensitive and exact about what it can and cannot decide.

35 · Child labour and adoption (psychiatric aspects)

Why it matters clinically. Child labour and adoption are not diagnoses. They are contexts that can alter a child's exposure to adversity, the meanings given to symptoms, the people who can provide safety, and the relationship through which treatment is delivered. A psychiatric opinion is useful when it describes the child's current difficulties without collapsing the child into either a legal category or a family story.

Child labour requires attention to the working environment, coercion, abuse and interrupted developmental opportunities. Adoption requires attention to the child's life narrative, relationships and questions of belonging. Neither permits casual assumptions: a working child may be silent without being symptom-free, and an adopted child may have difficulties that are neither caused by adoption nor explained by it.

LABOUR	ADOPTION	FORMULATION	CARE
CONTEXT AND RISK	NARRATIVE AND RELATIONSHIP	BEFORE LABELS	SAFETY WITH DIGNITY

35.1 Psychiatric frame for child labour

Child labour is clinically important not because it supplies a diagnosis, but because work may organise a child's daily life around demand, fatigue, fear, adult control and restricted access to ordinary supports. The consultation should therefore ask what the work means in this child's life. Is it described as contribution to the family, a source of pride, an obligation, a punishment, a means of survival, or an experience the child cannot safely discuss? The answer changes the formulation and the safety response.

The psychiatric task is not to decide the legal status of employment from a clinic interview. It is to identify mental-state symptoms, functional effects, coercion, maltreatment, available support and immediate danger. Symptoms are assessed as symptoms, while the circumstances in which they arose are explored carefully.

RULE **In a working child, formulate exposure and safety before attributing behaviour to character.** A difficult or guarded presentation can be an adaptation to threat, exhaustion, divided loyalties or a learned expectation that adults will not help. It should prompt careful enquiry rather than a moral judgement about the child or family.

A useful formulation separates linked questions:

- What does the child experience during and around work, including supervision, control, injuries, humiliation, threats and contact with adults?
- What is the present psychiatric picture, including distress, behaviour, cognition, sleep, physical symptoms and functioning across settings?
- What protective relationships and practical alternatives are available if the child discloses harm or cannot return to the same environment?

This prevents a common clinical collapse in which social hardship is treated as an explanation that ends assessment. Poverty may be relevant to why a child works, yet it does not make abuse, coercion or treatable distress inevitable or unimportant. Conversely, the presence of work does not establish a particular psychiatric disorder. The formulation must make room for agency and strengths as well as risk: a child may be caring for siblings, preserving school contact, seeking help, or relying on a trusted adult. These features can guide engagement and planning.

GOOD TO REMEMBER

Ask to speak with the child in a developmentally appropriate private setting when possible, while explaining the limits of confidentiality in plain language. The child should know that concern about safety may require the clinician to involve others; promises of absolute secrecy are unsafe and undermine trust when they cannot be kept.

35.2 What the evidence supports, and what it does not

Available multi-country evidence associates child labour with a **higher prevalence of mental and behavioural disorders** than among non-working children, and also links it with **one or**

more forms of abuse. This is an important clinical signal: the working situation should raise the threshold for complacency and make direct, sensitive enquiry essential.

Association is not a shortcut to individual causation. A child may have entered work after prior adversity, family illness, educational difficulty or displacement; the work setting may add new stressors; and symptoms may reflect several interacting pathways. In an examination answer, this is the difference between a contextual formulation and a slogan. The psychiatrist can state that work is a relevant exposure and then show how the child's own chronology, relationships, symptoms and protective factors support the formulation.

Chronology is particularly valuable. Explore what was present before work began, what changed after the work arrangement changed, and whether symptoms vary with particular people, places or demands. Ask about fear of going to work, ability to leave, payment or withholding of payment, access to food, rest, school and healthcare, injuries, sexual boundary violations, violence, and retaliation for disclosure. Use neutral language and avoid leading questions. If the child gives a partial account, do not turn the consultation into an interrogation. Clarify only what is needed for care and protection, document the child's words accurately, and link the child to the safeguarding response owned in the child-abuse management section.

TRAP **Do not diagnose trauma, conduct pathology or malingering from a work history alone.** The work history is a high-value contextual finding, not a substitute for psychiatric assessment. Over-attribution can miss unrelated illness; under-attribution can normalise danger.

CLINICAL QUESTION	WHY IT CHANGES THE FORMULATION	HOW TO RESPOND IN THE INTERVIEW
What is the child expected to do?	Task demands may explain fatigue, fear, injury or absence from ordinary settings.	Invite a concrete account without asking the child to justify the arrangement.
Who controls the work setting?	Control, surveillance and dependence shape both risk and freedom to disclose.	Explore trusted adults and whether the child can speak safely.
What changed in mood, behaviour or sleep?	A symptom timeline tests the proposed link without assuming it.	Ask for examples and variation across settings.
What happens if the child refuses or seeks help?	Retaliation risk determines how safely any plan can be made.	Do not encourage confrontation; activate appropriate protection pathways.
Who can provide immediate support?	Support figures are part of both risk assessment and recovery.	Map safe contacts with the child, not only with accompanying adults.

When a history suggests abuse or unsafe conditions, the clinician must not try to manage the case as a private therapeutic problem. Recognition, protection, reporting, referral and treatment are the clinical safeguarding response taught in the child-abuse management section. Child sexual

abuse assessment has its own forensic and psychiatric framework. General assessment should follow the chapter's Principles of child psychiatric history and examination.

IN INDIA

The principal statutory reference is **The Child and Adolescent Labour (Prohibition and Regulation) Act, 1986**. Its amendment record includes the **Child Labour (Prohibition and Regulation) Amendment Act**, enacted in **2016**. For the psychiatrist, the practical point is to recognise the statute as a protection context, while leaving legal interpretation and statutory procedure to the relevant legal and child-protection services.

35.3 Adoption as a developmental and relational context

Adoption should be approached as part of a child's personal and family narrative, not as a pathological event. The clinical question is not whether a child is adopted, but how adoption is understood, spoken about and lived within this family. A child may have questions about origins, separation, belonging, resemblance, loyalty, loss or difference. These questions can emerge indirectly through behaviour, schoolwork, peer relationships or conflict at home. They deserve curiosity rather than reassurance that closes the conversation.

Adoption communication openness matters because greater openness is linked to healthier family dynamics and more positive child adjustment. Openness is not merely a disclosure event. It is an ongoing family capacity to answer questions honestly at a level the child can use, to tolerate changing feelings, and to invite the child's perspective without demanding gratitude or emotional certainty. In practice, the clinician listens for whether the child is allowed to ask, whether parents can acknowledge what they do not know, and whether difficult feelings can be held without being interpreted as rejection.

There is a difference between privacy and secrecy. Families may reasonably protect personal information and decide how broadly to share it. Secrecy, however, can make the child responsible for managing adults' discomfort and can turn normal curiosity into a forbidden subject. Equally, disclosure delivered abruptly, as a weapon during conflict, or with excessive detail can overwhelm the child. The clinical aim is not to prescribe a uniform family script. It is to support a truthful, sensitive and revisitable conversation that matches the child's capacity and questions.

MNEMONIC

OPEN

Offer questions, **P**ace information, **E**xplore feelings, and **N**ame what is not known. This is a communication stance, not a rigid sequence or a test of parental adequacy.

Parents may fear that discussing adoption will destabilise the child or weaken attachment. That fear is understandable, particularly when family life has already included loss or uncertainty. The therapeutic conversation can make space for parental anxiety while retaining the child's right to experience and express mixed feelings. Help parents distinguish the child's question from an accusation. “Why was I adopted?” may be a question about belonging, origins, anger, grief,

fantasy or ordinary developmental curiosity. Its meaning must be explored with the child rather than supplied by an adult.

PITFALL

Do not treat a parent's discomfort with adoption talk as proof of poor parenting, or a child's curiosity as proof of psychopathology. Both may be understandable starting points for careful family work. The risk lies in shutting down the conversation, not in the existence of difficult questions.

35.4 Formulating difficulties in an adopted child

Attachment difficulties and **adoption-related attributions** can undermine self-esteem, identity, relationships and well-being. This directs attention to process rather than to a simplistic explanation that adoption itself caused the difficulty. A formulation asks what the child has inferred about self and others, what experiences sustain those inferences, how caregivers respond, and where the child finds safety, continuity and competence.

Some children may carry a painful personal explanation for separation or adoption, such as an idea that they were unwanted, defective, disloyal, or obliged to prove that they belong. Such meanings can influence mood, conflict, help-seeking and relationships, but they should not be assumed merely because the child was adopted. The psychiatrist should test the formulation against the child's language and behaviour, the caregivers' account, school context, current stressors and any relevant history available to the family. Where information is incomplete, say so and avoid inventing a coherent story on the child's behalf.

Work with the family often begins by strengthening reflective conversation. Caregivers can be helped to notice the feeling beneath an apparently provocative question or behaviour, respond without immediate correction, and return to the subject later if emotions are high. Individual work may offer the child a place to make sense of conflicting feelings without forcing disclosure to parents before the child is ready. Joint conversations can then be planned around a shared purpose: improving understanding, not extracting a confession or deciding whose version is correct.

The clinician should also resist diagnostic overshadowing. Adopted children can have the same range of psychiatric presentations as other children, and an adoption history should neither be ignored nor allowed to explain everything. Assess presenting symptoms and impairment using the general child psychiatric framework. Refer to the relevant disorder chapters when a disorder-specific assessment or treatment is indicated, including the Child behavioural, emotional and other disorders notes and the Intellectual disability and autism spectrum disorder notes.

RULE **Use adoption history to enlarge the formulation, never to replace it.** Adoption may shape meanings, relationships and the available narrative, but diagnostic reasoning still depends on the child's current presentation, developmental context and evidence from appropriate informants.

35.5 Boundaries, law and the psychiatrist's role

Psychiatrists frequently encounter adoption questions in situations of conflict, anxiety about disclosure, school difficulty, attachment concerns or a request for a certificate. The clinician's role is to assess mental health needs, support communication and document findings within competence. It is not to make unsupported predictions about family suitability, to validate an adult's account over another, or to convert a therapeutic formulation into a legal conclusion.

India's central regulatory reference is the **Adoption Regulations**, **2022**, notified on **23 September 2022**. Adoption law and the fitness of adoptive parents are addressed in the Mental health legislation and forensic psychiatry notes. In a clinical setting, the safest contribution is a clear account of symptoms, functioning, strengths, risks, interventions offered and the limits of the opinion.

TRAP **Do not confuse a therapeutic opinion with a legal fitness opinion.** A helpful account of a child's distress and family interaction does not by itself answer legal questions about adoption procedure or parental suitability. Stay within the referral question and state the limits of inference.

Child labour and adoption are formulation contexts: assess the child carefully, protect safety, and work with the meanings and relationships around the child without turning context into diagnosis.

36 · Bullying and its mental health consequences

Bullying is a clinical exposure, not merely a school-discipline problem. A child may present with distress or an apparently unexplained change in functioning while the peer context remains undisclosed. The psychiatrist's task is to make that context speakable, formulate its relation to the presenting difficulty, and ensure that risk is not missed. This is especially important when the child is ashamed, fears retaliation, has been told to ignore the behaviour, or assumes that adults will dismiss it as ordinary peer conflict.

This section concerns **bullying** and its mental-health consequences. It does not replace the assessment of the childhood disorders themselves, which is addressed in the Child behavioural, emotional and other disorders notes, nor the general child psychiatric assessment framework, which is addressed elsewhere in this chapter. The useful clinical question is not simply, “Has bullying occurred?” It is: what has happened to this child’s sense of safety, agency, belonging, self-appraisal, relationships, and capacity to function?

36.1 Defining the clinical exposure

Traditional bullying is not synonymous with every unpleasant peer interaction. Its defining structure is **intentional and repeated harm** in a relationship marked by a **power imbalance**. Power need not be overt; explore how it operates in the peer relationship and how it limits the target’s ability to stop or escape the pattern. An isolated disagreement can be distressing; bullying becomes a different kind of exposure when harm is organised around domination and recurrence.

Intentional	Repeated	Power	Digital channel
HARM IS DIRECTED	THE PATTERN PERSISTS	RESISTANCE IS CONSTRAINED	MAY EXTEND EXPOSURE

RULE **Call it bullying only after examining intent, repetition, and power.** This protects the child from minimisation while also preventing the term from becoming a label for all peer conflict. The distinction matters because a child caught in a power-imbalanced pattern may need a different level of protection, follow-through, and clinical attention than a child negotiating an isolated quarrel.

The child's account remains central, but it should not be treated as a forensic contest in the clinic. A child may describe a sequence rather than use the word "bullying." Ask for what happens before, during, and after contact with the peer group; who joins, watches, laughs, excludes, records, forwards, or remains silent; and what the child believes will happen if they tell an adult. This clarifies the lived structure of power without forcing a legalistic vocabulary on the child.

TRAP **Do not dismiss a pattern as "normal teasing" because the children sometimes exchange remarks.** Mutuality at the surface does not rule out a coercive pattern. The relevant question is whether a child is repeatedly positioned to absorb harm with less social power and less freedom to disengage.

36.2 Cyberbullying changes the setting, not the clinical seriousness

Cyberbullying refers to bullying conducted **over the Internet or by text message**. A complementary conduct-based description emphasises **online harassment, defamation, or intimidation intended to degrade, belittle, or harass**. These definitions are useful because they prevent a false split between "real-world" and digital harm. The medium changes how exposure is delivered and witnessed; the clinical work still concerns humiliation, threat, loss of control, and the effects of peer power.

CLINICAL AXIS	TRADITIONAL BULLYING	CYBERBULLYING
Setting	Peer harm in an in-person social environment	Online or text-message channel
Useful enquiry	Ask how the peer pattern operates around school, transport, activities, and friendships.	Ask how messages, posts, group interactions, images, or account access are affecting the child.
Clinical formulation	Attend to repeated harm and constrained escape.	Attend to the same peer-power process and to the child's experience of continuing access to the harm.
Common error	Reducing the account to a quarrel.	Reducing the account to "screen time" rather than interpersonal victimisation.

Digital material may create a painful sense that the audience cannot be contained. Even when the child cannot know who has seen something, anticipation itself can maintain vigilance, shame, and avoidance. Conversely, an adult who focuses only on the device can miss the relational

system: peers, bystanders, group allegiances, and the child's fear of social exclusion. The clinician should ask in ordinary language about where peer contact continues after school, rather than assuming that the child will volunteer this part of the story.

IN INDIA

A defensible prevalence figure for cyberbullying among school-going children and adolescents in India is **not established** by the material available for this section. Do not transfer a figure from a different population into child practice. The exam-safe and clinically honest position is to recognise cyberbullying as a relevant adolescent concern, enquire about it directly, and avoid unsupported numerical claims.

36.3 From victimisation to psychiatric presentation

Bullying can function as a continuing interpersonal stressor. Its psychological force is rarely captured by the visible incident alone. Repeated anticipation of ridicule or attack can reshape attention toward threat; public humiliation can alter self-appraisal; exclusion can turn ordinary school and peer settings into cues for alarm. A child may then look oppositional, withdrawn, "unmotivated," or preoccupied when the more coherent formulation is that they are trying to manage an unsafe social world.

Among Indian school-going children and adolescents who experience cyberbullying victimisation, reported mental-health consequences include **depression**, **anxiety**, and **low self-esteem**. These are not interchangeable outcomes. Each calls for a formulation that identifies the child's dominant experience and its functional impact, rather than treating "stress" as an adequate endpoint. This protects against the common error of using the bullying history as a substitute for understanding the actual psychiatric presentation.

Association is not automatic proof that bullying explains every symptom. Some children have pre-existing vulnerabilities, concurrent family adversity, neurodevelopmental differences, interpersonal difficulties, or an emerging disorder that changes both their peer experience and the way they report it. The appropriate stance is neither credulity without inquiry nor scepticism that makes disclosure impossible. Establish chronology, changes from the child's own baseline, the meaning the child assigns to the events, and whether symptoms fluctuate with contact or anticipated contact. This allows bullying to be placed in a formulation as a precipitant, perpetuating factor, consequence, or a combination of these.

GOOD TO REMEMBER

If the history includes **suicidal thoughts**, **self-harm**, or **suicidal-behaviour attempts**, assess current safety directly and act on the level of risk. Bullying may be the context that opens the conversation; it must not become a reason to postpone a full safety response.

36.4 The consultation: making disclosure possible and formulation useful

Children often test whether the clinician is going to minimise, sensationalise, or immediately take control away from them. Begin with a private, developmentally appropriate conversation when

possible, explain the limits of confidentiality in language the child can understand, and signal that the purpose of questions is protection and help rather than punishment. The child may be loyal to peers, worried about being labelled a complainant, or frightened that adults will make an intervention that increases retaliation. These concerns are clinical data, not resistance to be argued away.

- Invite a narrative: what happened, who was involved, what the child did, and what followed.
- Ask about avoidance, distress before peer contact, changes in self-talk, and the child's sense of safety.
- Ask directly about thoughts of death, self-harm, and harm to others when the presentation indicates risk.
- Clarify what the child wants adults to understand and what outcome they fear most.

Collateral accounts can add context, but they are not a mechanism for overriding the child. Parents may notice changes without knowing their meaning. Teachers may see a social interaction but not the private messages or the group dynamics surrounding it. A careful record separates reported events, observed mental state, collateral information, and the clinician's formulation. This makes later communication clearer and protects against the common drift from a child's narrative into an adult's assumption about what "really happened."

PITFALL

Do not make the consultation a demand for screenshots, perfect chronology, or immediate corroboration before offering containment. A distressed child may have deleted material, avoided looking at it, or be unable to recount it in a linear way. Clinical care begins with safety, validation, and careful inquiry; where safety requires wider action, use the applicable local pathway.

36.5 Treatment principles: restore agency without narrowing the problem

Treatment should address the child's symptoms, meaning-making, and social context. Validation is not the same as confirming every unverified detail; it means communicating that the distress is intelligible and worthy of help. Work can help a child name emotions, notice shame-based or hopeless conclusions about the self, distinguish danger cues from global expectations of rejection, and rebuild activities and relationships that have contracted around fear. The exact psychological intervention is selected according to the child's presentation and developmental capacity, not according to the label of bullying alone.

Parents need help to move between opposing unhelpful poles: dismissive reassurance and intrusive takeover. They can communicate belief in the child's distress, keep communication open, monitor changes in safety, and participate in a proportionate plan. Where school involvement is needed, clinical communication should be purposeful: describe functional impact and the need for a safe response, while sharing only what is necessary. This section remains focused on the psychiatric consequences for the individual child rather than on programme design.

MNEMONIC

PAUSE

Privacy for disclosure, **A**cknowledge distress, **U**nderstand the peer-power pattern, **S**creen for safety, and **E**ngage the child and caregivers in a proportionate plan. It is a consultation spine, not a substitute for assessment or safeguarding procedures.

Medication is not a treatment for bullying itself. When a child has a psychiatric syndrome requiring treatment, prescribe and monitor according to the relevant disorder guidance and the child psychopharmacology sections of this chapter. Avoid using a medicine decision as a way of bypassing an unresolved exposure. Equally, do not withhold indicated treatment on the theory that changing the peer environment alone will resolve every symptom. A good formulation keeps both the clinical syndrome and the social stressor in view.

36.6 Risk, documentation, and the candidate's clinical answer

Risk is dynamic. Escalating humiliation, threatened exposure, social isolation, hopelessness, a recent self-harm act, or a child's belief that there is no safe adult can alter urgency. Ask about what keeps the child going as well as what increases danger: a trusted relationship, a valued role, future plans, or willingness to accept help may inform the immediate plan. Do not promise secrecy that cannot be maintained if safety requires adult action, but do explain in advance, as far as possible, what information may need to be shared and why.

The record should make clinical reasoning visible. Document the child's words where they clarify meaning, the pattern alleged, the mental-health effects, the risk inquiry, relevant collateral, protective factors, and the agreed next steps. Avoid pejorative shorthand such as "attention seeking" or "peer issue." Such language prematurely closes formulation and may influence later professionals to underestimate a potentially serious exposure.

Bullying is defined by intentional, repeated harm and a power imbalance; when it is disclosed, assess its psychiatric impact and current safety rather than treating it as routine peer conflict.

Cross-cutting synthesis

37 · Cross-cutting synthesis

Why the synthesis matters. A child does not arrive in separate assessment, prescribing, therapy, service and protection compartments. The clinician must make one coherent plan from information that arrives at different times, from different people, and sometimes in conditions of risk. Marks are earned here by showing the movement from one domain to the next: not merely naming each domain, but explaining why a finding in one changes the action in another.

The organising question is not, "Which intervention belongs to which discipline?" It is, "What must change for this child, what could prevent that change, and who must know what next?" A

clinical formulation is useful only when it guides the next decision and remains open to revision. The parts of care must **interlock**: assessment directs the initial plan; prescribing creates observation duties; observation may reveal risk; protection obligations alter the order of care; and service access determines whether psychological work can actually be delivered.

FORMULATION	PRESCRIBING	PROTECTION	SERVICES
WHAT CHANGES	WHAT TO WATCH	WHAT MUST HAPPEN	WHAT IS POSSIBLE

37.1 Begin with the decision, not the silo

The assessment is not a prelude that ends when treatment begins. It establishes the decision that has to be made now, the information on which that decision rests, and the information that could reverse it. The general child psychiatric assessment framework, interviewing, developmental testing, screening, rating tools and neuropsychological assessment are taught in their respective sections. Their synthesis value lies in converting their findings into a shared account of the child's difficulties, capacities, relationships, daily setting and immediate risks.

At this point, the clinician should distinguish a **presenting complaint** from a **treatment target**. The former is the concern brought by the family, school or another agency. The latter is the change that the current plan can reasonably try to produce. If the account is incomplete, contradictory, or shaped by an unsafe setting, the correct response may be to clarify the formulation before choosing an intervention. This is not therapeutic delay for its own sake; it prevents an apparently efficient plan from treating the wrong problem or placing an impossible burden on the child.

RULE **Every intervention must answer a question raised by the formulation.** If a proposed intervention cannot be linked to a stated target, a relevant risk or a feasible route of delivery, it is a habit rather than a plan.

- State what the current assessment permits the team to act on.
- State what uncertainty needs follow-up rather than concealment.
- State which person or setting can confirm whether the intended change is occurring.

37.2 Let assessment alter the prescribing decision

Child prescribing is not a detachable response to a label. Its principles, developmental considerations, drug-specific practice, off-label questions and consent framework belong to the psychopharmacology sections. The cross-cutting task is to make the assessment visible in the prescribing decision. A child's developmental communication, physical health context, pattern of impairment, family understanding, competing explanations for change and access to follow-up can each determine whether medication is appropriate now, whether another intervention must lead, or whether a proposed trial needs to wait for safer clarification.

A prescription therefore carries a **clinical rationale**, not merely an instruction. The rationale identifies the target, the anticipated observation and the contingency if the observed course does not fit the formulation. It protects against the common drift in which a medicine becomes the

whole plan because it is the most concrete action available. Psychological intervention, educational support and family work do not become optional simply because medication has been considered. Conversely, therapy should not be presented as a substitute for a review when assessment indicates that a prescribing question requires one.

ASSESSMENT CONCLUSION	HANDOFF TO THE PRESCRIBING PLAN	QUESTION RETURNED TO FOLLOW-UP
The target problem is clear	Link the intervention to that target	Is the intended change visible in ordinary life?
The account remains uncertain	Preserve uncertainty in the plan	What new information would change the decision?
Family or setting constraints are prominent	Test whether the plan can be carried out safely	Who can observe and communicate concerns?
Risk is present or emerging	Reorder care around safety and protection	Has the required pathway been activated?

PITFALL

Do not write “assessment completed, medication started” as though the first phrase has no bearing on the second. That wording hides the formulation, makes later review arbitrary and can obscure why a non-pharmacological or protective action was prioritised.

37.3 Treat monitoring as a new source of assessment

Once a prescribing decision is made, monitoring is not an administrative afterthought. The detailed monitoring-and-consent framework and drug-specific schedules are taught elsewhere. In the integrated plan, follow-up is a **monitoring loop**: it asks whether the target changed, whether the child’s functioning changed in the settings that matter, whether an unwanted effect or new difficulty has appeared, and whether the caregivers can still implement the plan they agreed to.

This loop can validate the original formulation, qualify it, or expose that the team has been looking at only one part of the child’s life. A change reported by one adult may have a different meaning when connected with the child’s own account, school experience, peer context or home atmosphere. The clinician should neither dismiss discordant accounts as nuisance nor automatically average them into a false consensus. Disagreement is often the handoff back to assessment: it identifies where further understanding is needed before escalating, continuing or changing treatment.

The record should make responsibility visible. It should show what is being watched, how the family can raise a concern, and what event requires earlier contact or a change in the plan. This is a continuity task, not a demand that one clinician personally observe every setting. The plan is safe only if its observers understand their role and the team knows how information will return.

GOOD TO REMEMBER

A useful review question is not simply whether the child is "better." Ask whether the observed change supports the working formulation and whether it has made the child safer, more able to participate, or more reachable for the next intervention.

37.4 Allow monitoring to surface safeguarding concerns

Follow-up sometimes reveals more than response to treatment. New information may become a **safeguarding signal**. The types and indicators of abuse, child sexual abuse assessment, and the clinical response to abuse are taught in the protection sections. The synthesis point is that a new concern is not a reason to defer attention until the next routine assessment. It changes the clinical task immediately from simple treatment review to safety-oriented decision-making.

At that seam, the clinician should separate two questions that are often mistakenly fused. One question is what is needed for the child's current mental health care. The other is what must be done because the information raises a safeguarding concern. Treatment uncertainty does not cancel a protection concern, and a protection process does not remove the need to address distress, functioning and engagement. They proceed in a coordinated order, with the child's safety setting the limit on what can be attempted therapeutically.

TRAP **Do not wait for clinical certainty before recognising a possible statutory pathway.** A diagnostic formulation and a safeguarding response answer different questions; confusing them can leave the child without timely protection.

- Reclassify the contact as a potential safety handoff, not only a treatment review.
- Use the relevant protection and reporting route without turning the clinic visit into an improvised investigation.
- Keep a clinical route of contact while the necessary services take their part.

37.5 Put statutory duty beside, not after, treatment

Where a safeguarding concern triggers a **statutory pathway**, the legal duty and child-friendly procedures are governed by the child-protection and juvenile-justice sections of this chapter. The psychiatrist's synthesis task is to ensure that the legal and clinical tracks are connected without allowing either to swallow the other. The protection handoff should tell the receiving service what is known clinically, what requires urgent attention, and how further contact can be made without increasing risk to the child.

Protection also changes the therapeutic frame. A child cannot be asked to practise trust, regulation, disclosure or family communication in a plan that ignores an unsafe relationship or setting. The immediate work may need to focus on stabilisation, engagement and safe contact while the appropriate statutory and service responses proceed. This is not a lesser form of therapy. It is the precondition for therapy that has a realistic chance of being used.

IN INDIA

An integrated plan must connect the clinical team with the relevant local child-protection and child-development services rather than treating referral as a discharge destination. The statutory route, protection response and national service platforms are set out in the dedicated sections; the psychiatrist's role here is to maintain a clear clinical handoff and a continuing treatment plan.

37.6 Make service fit part of the treatment formulation

Therapy is delivered through a child's actual environment, not through the referral letter. Play therapy, behavioural work and parent management, family interventions, cognitive behaviour therapy, educational intervention and early intervention are taught in their own sections. Their feasibility depends on a **service fit**: whether the child can attend, whether a caregiver can participate, whether the school can support a consistent plan, whether communication is possible across professionals, and whether protection arrangements permit the proposed work.

Services are therefore active parts of treatment. A school mental-health pathway may make observation and support possible. A child-development platform may make developmental, family or educational work reachable. A referral to protection services may create the safety and continuity without which therapy cannot proceed. The relevant Indian service platforms are described in the sections on school mental health, the child health screening programme and child-development services. The synthesis is to decide which service changes the child's ordinary environment enough for treatment to become practicable.

The handoff must be specific in purpose even when it is brief: what has been assessed, what the receiving service is being asked to do, what information may be shared, and when the clinical team will reassess the plan. A generic referral transfers neither reasoning nor responsibility. It also leaves families to coordinate systems that were designed for professionals to navigate.

MNEMONIC

TRACE

Track the formulation, **R**elate each intervention to its target, **A**ct on new risk information, **C**onnect statutory and service pathways, and **E**nable the therapeutic work that the child can actually use.

37.7 Close the loop without closing the formulation

Integrated care is iterative. Each contact should return the team to the same chain: current formulation, chosen intervention, observed consequence, new risk information, service capacity and revised plan. The purpose is not paperwork completeness. It is to prevent a child from being lost at the seams - assessed but not followed up, prescribed for but not understood, referred but not treated, protected but then left without recovery-oriented care.

Childhood disorders themselves are cross-referred to the Child behavioural, emotional and other disorders notes; ADHD and its treatment to the ADHD and specific learning/communication disorders notes; intellectual disability and autism spectrum disorder to the Intellectual disability

and autism spectrum disorder notes; and temperament and developmental expectations to the Normal child development and milestones notes. Questions of general criminal responsibility, the Mental Healthcare Act and adult forensic assessment belong to the Mental health legislation and forensic psychiatry notes. These boundaries matter because an integrated plan is not a licence to repeat every domain. It is the disciplined account of how each domain changes the next clinical move.

> The best child psychiatry plan is a visible chain of handoffs: assessment informs treatment, treatment generates monitoring, monitoring can activate protection, and services make recovery work possible.

Apply and consolidate

38 · Applying the chapter

Why these cases matter. A child psychiatry vignette tests whether the candidate can make a safe next move when the story is incomplete. The marks lie in showing a disciplined sequence: hear the child and family, identify what needs deciding now, state the information that changes that decision, and connect the child to the right help. It is not an invitation to display a long differential diagnosis or to recite a service manual.

In a standalone answer, the **clinical formulation** is the bridge between a child's presentation and an action. It keeps symptoms, development, relationships, school context, physical health, risk and strengths in the same frame. The diagnosis may be part of clinician reasoning where appropriate, but it is not a label to be delivered to the child or family in the answer. Explain the difficulties and the proposed help in language they can use.

PRESCRIBE	ASSESS	LINK	PROTECT
ONLY AFTER A DECISION FRAME	ACROSS INFORMANTS AND SETTINGS	NEEDS TO USABLE SERVICES	WHEN DISCLOSURE CHANGES SAFETY

38.1 Reading and writing a clinical vignette

A good response begins by locating the decision point. The presenting complaint is often deliberately noisy: a school concern may conceal unmet learning needs, a request for medicine may be a request for containment, and a disclosure may be offered after the child has tested whether the clinician is safe to tell. The candidate should neither flatten this complexity into a label nor become so comprehensive that the urgent decision disappears.

DOMAIN IN THE STEM	WHAT THE ANSWER MUST SHOW	SAFE CLOSING ACTION
Request for a medicine	What is being treated, what has already been tried, and whether benefit, harm and agreement can be reviewed	A reasoned prescribing decision with planned follow-up
Concern about behaviour or progress	Child's account, developmental context, functioning, observations and accounts from relevant settings	A focused assessment plan and feedback formulation
Family unable to sustain care	Which participation barrier matters most and which agency can address it	A coordinated referral with responsibility for follow-through
Possible abuse or exploitation	Immediate safety, a careful response to disclosure, documentation and the safeguarding pathway	Protection, statutory action and therapeutic support

The following vignette answers use the same spine.

- Name the immediate decision rather than merely naming a condition.
- Give the clinical reasoning that would change the decision.
- End with an action, communication plan and review responsibility.

RULE **Answer the decision in front of you, then show why it is safe.** A broad formulation earns its place only when it clarifies the next action for this child, in this setting, with this family.

MNEMONIC

PAST: Pause, Assess, Support, Take action to protect

Use this as the closing spine of a vignette. **Pause** before reflex prescribing; **Assess** the child in context; **Support** the child through family, school and services; and **Take action to protect** when safety is in question. It is a reasoning aid, not a substitute for the detailed frameworks elsewhere in the chapter.

38.2 A prescribing decision when the family wants a quick answer

Presentation. A school-aged child is brought after repeated complaints of restlessness, conflict and incomplete work. The parent asks for a medicine because the school has said that the child must "settle down". The child looks exhausted, says that lessons feel impossible when classmates mock the errors, and reports sleeping poorly. The parent is angry with the school and expects a prescription at the end of the visit.

Decision point. Should the clinician start or change a psychotropic medicine at this consultation?

Reasoning the candidate must show. The request for medication is not yet a prescribing indication. The clinician needs to distinguish a persistent pattern from a recent contextual

change, understand the child's experience as well as the parent's account, and ask what happens across home, school and other settings. The answer should identify sleep, distress, peer experiences, learning demands, physical contributors, safety and previous interventions as information that could alter the formulation. It should also establish what the family understands and what the child is willing to discuss, rather than treating the child as a passive recipient of an adult decision.

The relevant **prescribing frame** is then applied, not reproduced from memory. If a medicine is contemplated, its target difficulties, expected benefit, possible unwanted effects, consent and assent process, and route for review must be made explicit. If the available account is too incomplete to support a safe choice, delaying the prescription is an active clinical decision, not therapeutic neglect. A clinician may still address immediate distress, coordinate with the school and arrange prompt reassessment while the assessment proceeds.

Answer. Do not prescribe simply to meet the school's demand. Complete a focused multi-setting assessment and discuss the formulation with the child and parent in plain language: "We need to understand what is making school so difficult before deciding whether medicine would help." Offer practical interim support, obtain the information required for a safe decision, and return to treatment selection using the child-prescribing and monitoring frameworks. If the eventual formulation concerns ADHD, its stimulant and non-stimulant treatment belongs in *the ADHD and specific learning/communication disorders notes*; if it concerns another childhood disorder, consult *the Child behavioural, emotional and other disorders notes*.

> **GOOD TO REMEMBER**
>
> A child's reluctance, a parent's urgency and a school's request are all clinical data. None alone decides the prescription. The interview should leave the family with a comprehensible plan even when the medicine decision is deferred.

38.3 An assessment when the accounts do not agree

Presentation. A child is referred because teachers describe disruptive behaviour and falling classroom performance. At home, the caregiver sees a quiet child who spends long periods drawing and has few arguments. In the interview, the child speaks little at first, then says that school feels frightening and that adults assume deliberate defiance. The referral letter asks for a "test" to establish what is wrong.

Decision point. What assessment should be arranged, and how should the disagreement between adults be handled?

Reasoning the candidate must show. Contradictory accounts are not a reason to choose the most authoritative informant. They are a finding that requires explanation. The candidate should seek a **multi-informant assessment**: the child's own narrative, developmental and medical history, caregiver observations, school examples, direct clinical observation, and information about functioning in relevant environments. The question is not whether either adult is correct

but what differs between settings: task demands, relationships, communication expectations, sensory load, peer safety, family stress or the way behaviour is interpreted.

Assessment must be purposeful. A developmental, adaptive, educational or neuropsychological evaluation is chosen only when it answers a formulation question that cannot otherwise be answered. A score should not replace the child's history or be used as a verdict. The candidate should describe the **functional impact** that needs clarifying - participation in learning, relationships, self-care, play, emotional regulation or daily routines - without importing cut-offs or proprietary test content. The child's strengths, including the sustained interest in drawing, matter because they can shape engagement and school planning.

Answer. Explain to the caregiver and school that the assessment will bring together accounts rather than declare either side wrong. Obtain examples of antecedents, behaviour and consequences in each setting; interview and observe the child in an age-appropriate way; review development and health; and select further testing only for a defined question. Feed back a shared formulation that describes needs and strengths without naming a diagnosis to the child or family. For the general assessment framework, see the chapter section on child psychiatric history and examination; for developmental and adaptive screening, and for the formal test batteries, use the relevant assessment sections. Intellectual disability and autism spectrum disorder are addressed in *the Intellectual disability and autism spectrum disorder notes*, and developmental expectations belong in *the Normal child development and milestones notes*.

TRAP **Do not turn a request for "a test" into a test-led assessment.** Instruments answer selected questions; they do not reconcile conflicting accounts, establish context or determine what the child and family need next.

38.4 A services referral that must be more than a name on paper

Presentation. A child has attended intermittently after a recent family disruption. The caregiver can travel only with difficulty, the school is considering exclusion, and a relative says that the family should seek a disability certificate before accepting any other help. The child wants to remain with familiar peers but says that nobody has explained what support might be possible. The immediate symptoms have been discussed, yet attendance and participation remain fragile.

Decision point. Is a generic referral enough, or does the clinician need to build a **service map** around the child's actual barriers?

Reasoning the candidate must show. Referral is a clinical intervention only when it reaches a service that can act on the stated problem. The candidate should identify the bottleneck: access to care, educational participation, family support, therapeutic work, social protection, transport, communication between agencies or an unrecognised safeguarding concern. A certificate may be relevant to future entitlements, but it is not a substitute for asking what will help the child participate now. Likewise, sending the family to multiple agencies without a named purpose transfers the coordination burden to the person least able to carry it.

The referral should link mental-health care with the child's everyday setting. This may include discussion with school, educational assessment and support, family intervention, developmental services, community follow-up or a social-work response, according to the formulation. The clinician remains responsible for making the reason for referral clear, obtaining appropriate agreement to share information, and checking whether the connection occurred. The child should hear a practical explanation: "We are asking these people to help make school and home more manageable," rather than a diagnostic label.

Answer. Make a coordinated referral plan with the caregiver and child. State the target for each contact, identify who will communicate with school, arrange follow-up that reviews participation rather than only symptoms, and address barriers that would make the plan fail. Use the chapter's sections on school mental health, RBSK and ICDS to select the appropriate Indian platform rather than treating services as interchangeable. If the child is at risk of harm or lacks safe care, move to the protection pathway instead of leaving that concern inside a routine referral.

IN INDIA

Families often encounter school, health, developmental and welfare systems as separate doors. The clinical task is to translate a formulation into a coordinated request that each service can understand, while retaining the family's voice and the child's participation.

38.5 A child-protection disclosure in the consultation room

Presentation. During a review attended by a caregiver, an adolescent asks to speak alone. The young person then describes unwanted sexual contact by someone known to the family and asks the psychiatrist not to tell anyone, fearing blame and disruption at home. There is no visible injury at the consultation. The caregiver outside has been pressing for medication because the adolescent has become withdrawn and irritable.

Decision point. How should the clinician respond in the room, and what must happen next?

Reasoning the candidate must show. The immediate task is a **safeguarding response**, not diagnostic classification and not an attempt to prove the account during a routine psychiatric interview. Thank the young person for telling, respond calmly, and avoid leading questions or repeated detailed questioning. Explain the limit of confidentiality honestly: the clinician will involve the appropriate people to help keep the young person safe. Assess immediate danger, identify whether a safe adult and safe place are available, and document the disclosure accurately in the child's own words as far as possible.

The candidate must then activate the hospital child-protection process and the applicable POCSO reporting and child-friendly care pathway. The response includes protection, medical and forensic referral where indicated, and ongoing mental-health support. A visible injury is not required for the disclosure to be taken seriously; equally, the clinician's role is not to make an evidentiary finding before seeking protection. Communication with the caregiver must be planned around safety, the child's wishes where they can be respected, and the statutory process.

Do not name a psychiatric diagnosis to the adolescent or family; describe distress as an understandable response and explain the supports being arranged.

Answer. Remain with the young person, ensure immediate safety, explain the next steps without making promises that cannot be kept, document carefully and initiate the safeguarding, reporting and referral pathway without delay for certainty. Arrange continuity of therapeutic support after the acute response. The detailed clinical response to abuse is in the child-abuse management section, and the statutory duties and procedures are in the POCSO section. General criminal responsibility and adult forensic assessment belong in *the Mental health legislation and forensic psychiatry notes*.

1. Listen without interrogation and acknowledge the disclosure.
2. Make safety, protection and accurate documentation the immediate priorities.
3. Use the formal safeguarding pathway while preserving therapeutic continuity.

PITFALL

Never promise absolute secrecy before hearing what the child needs to say. A promise that must later be broken can feel like a second betrayal. State privacy and its safety limits early, then explain each necessary disclosure as transparently as possible.

In every vignette, show the child's experience, the decision that cannot wait, the reasoning that makes it safe, and the person who will carry the next action.

39 · Consolidation

The final task is not to reread the chapter, but to retrieve it. A child psychiatry answer becomes clinically useful only when the candidate can recognise which part of the system is being tested, select the relevant frame, and state the next defensible action without being handed a menu. This closing section turns the chapter into an active recall exercise. The prompts are deliberately answer-free: pause, write or say the answer, then return to the relevant section only to correct what was missed.

Retrieval is more demanding than recognition. A familiar heading may create the impression of mastery while leaving the clinician unable to organise an assessment, explain a prescription, locate an appropriate service, or respond safely to a disclosure. Use each prompt to construct a brief **problem representation**: what is happening, whose account is needed, what decision is pending, and what could be unsafe if delayed. That habit integrates the chapter without turning its separate components into a blurred checklist.

PRESCRIBE	ASSESS	TREAT	PROTECT
RECALL THE FRAME	RECALL THE SOURCES	RECALL THE FIT	RECALL THE RESPONSE

39.1 How to use the closing prompts

A useful **retrieval cue** names a decision, not merely a heading. Before answering, decide whether the question is principally about prescribing, assessment, psychological intervention, access to support, or safety. Several domains can be relevant, but identify the domain that sets the immediate **decision threshold**. State that priority at the outset, then bring in adjacent domains only where they change the decision.

RULE **Retrieve the clinical action before reopening the text.** The point of review is to detect a gap in reasoning, not to replace reasoning with recognition. A short spoken answer is sufficient when it includes the child, the caregivers, the setting and the immediate clinical responsibility.

Do not treat a weak answer as a reason to copy a paragraph. Identify the missing link instead. It may be an absent informant, an unasked developmental question, a poorly matched intervention, an overlooked school or community pathway, or a safety obligation that should have changed the order of events. Revisit that missing link and attempt the prompt again after an interval. This makes uncertainty visible early, when it is still easy to repair.

- Answer from memory in complete clinical sentences before checking the chapter.
- When your answer is incomplete, label the missing step rather than memorising isolated phrases.
- Use the next patient encounter to test whether the recalled framework changes what you ask, document or arrange.

PITFALL

Passive rereading can feel fluent because the wording is familiar. It does not show whether you can choose between competing priorities when a child, caregiver, school and service system each provide only part of the picture.

39.2 Master spine for the chapter

The chapter can be held together by **PATS**. It is a navigation cue rather than a substitute for the detailed sections. On every revision pass, ask whether the case needs a prescribing frame, an assessment frame, a therapy frame, a service frame, or a safeguarding frame. The same child may require several of these, but the mnemonic prevents a familiar diagnosis from crowding out the surrounding system of care.

MNEMONIC

PATS: Prescribing, Assessment, Therapy, Services, Safeguarding

Use the mnemonic to scan the chapter's linked domains. It is a prompt to ask what remains unaddressed, not a claim that every child needs every component at every encounter.

Why this matters in practice. A technically correct intervention may still fail if it is not grounded in a credible assessment, understood by the caregiving system, workable in the child's everyday setting, or safe to deliver. Conversely, a protection concern can change the sequence of

care even when a therapeutic plan is otherwise sound. The clinical skill is **cross-setting transfer**: carrying the formulation from the consultation room into family, school, community and protection contexts without losing the child's perspective.

GOOD TO REMEMBER

When a case feels complicated, do not add interventions indiscriminately. First ask which PATS domain is driving immediate risk or impairment, then identify the relevant collaborator or setting that must be brought into the plan.

39.3 Answer-free active recall prompts

Attempt the following without looking back. They are written as questions because the act of retrieval is the device. Do not convert the table into model answers: the value lies in exposing what cannot yet be reconstructed from memory.

CLINICAL DOMAIN	RETRIEVAL PROMPT	SELF-CHECK AFTER RECALLING
Pharmacology	Before initiating or changing a psychotropic medicine for a child, what prescribing, developmental, communication, monitoring and follow-up questions must you answer?	Have you distinguished the treatment decision from the wider monitoring-and-consent framework?
Assessment	How would you construct a child psychiatric assessment when accounts from the child, caregivers and other settings do not fully agree?	Did you include developmental context, direct observation and the appropriate role of structured tools?
Therapy	How would you choose and adapt psychological work when the child's needs, caregiver capacity and educational setting pull in different directions?	Have you explained why the chosen approach fits rather than simply named a therapy?
Services	What local health, school and community pathways could support a child whose needs cannot be met by a clinic appointment alone?	Can you describe how referral, collaboration and continuity would work in the child's setting?
Protection	When concern, injury, neglect or a disclosure raises a child-protection question, what must determine the immediate sequence of clinical action?	Have you separated recognition, safety, documentation, reporting, referral and therapeutic follow-through?

IN INDIA

For each services and protection prompt, practise naming the locally available pathway as well as the clinical rationale for using it. A generic referral answer is incomplete if it does not show how the child and caregivers will reach, understand and remain connected with support.

TRAP **Do not answer a systems question by reciting a disorder formulation alone.** The question may begin with symptoms, but marks and patient safety often turn on the next assessment source, treatment adaptation, service link or safeguarding responsibility.

39.4 Consolidating clinical judgement

The strongest final answer does not list every resource available to a child. It explains why a priority action comes first and how the rest of the plan follows. A **safeguarding lens** is especially important: it asks whether the ordinary pace of assessment or treatment is appropriate when safety, coercion, neglect or exploitation may be present. That lens does not replace clinical formulation. It determines whether the formulation can safely be acted upon.

For revision, convert each missed prompt into a small plan for re-learning. Return to the relevant section, identify the rule or distinction you failed to retrieve, and rehearse it in a fresh scenario. Then use PATS to check that the new answer still respects the child's developmental position, the caregiver relationship and the realities of the setting. This is how a chapter on systems becomes a method of practice rather than a collection of headings.

Before you close a child psychiatry case, ask: what must be prescribed, assessed, treated, connected and protected?

Previously asked

Genuine past questions from this chapter's territory, with their board of origin. One catalogued theory question falls inside child psychopharmacology, the child assessment battery, the therapeutic interventions, the service and policy context, or child protection and juvenile justice, and it is printed below exactly as it was set. No question is reconstructed, paraphrased into a new one, or invented to pad the list. The catalogue behind this list is a single board's record and is not a complete account of what has been asked, still less of what may be asked.

QUESTION	MARKS	ASKED
Play therapy	10	MUHS 2013

The shape of that question is worth reading closely. It is a bare noun phrase carrying ten marks, which is the examiner asking for a structured account rather than a definition: what play therapy is and why play is the medium, the non-directive and directive traditions, the technique, the indications and the limits, and the evidence. A candidate who writes four lines on what play therapy means has answered a two-mark question that was not asked.

TRAP **An unasked topic is not a low-yield topic.** The absence of a past essay is a fact about one board's recent papers, not about what an examiner may ask this year. This chapter carries two bodies of material that are examined far more often than the catalogue above suggests, because they are asked in the viva and as short notes rather than as set-piece essays: the paediatric doses, each scoped to its population and its indication, and the statutory duties under the child-protection and juvenile-justice framework. Prepare the discriminations, the doses and the statute, not the past paper.

The quick review

One table, read down the left column and cover the right. Every line is taught in full somewhere above and nothing here is new: each is that topic's single must-hold line, lifted verbatim from the section that teaches it, so a line you cannot recover is a section to reread rather than a fact to memorise here. Doses are deliberately not restated in this table; a dose is a fact about an indication in a population and belongs with the whole regimen where it is taught.

ASK	HOLD
CHILD PSYCHOPHARMACOLOGY	
PRINCIPLES OF PRESCRIBING PSYCHOTROPICS IN CHILDREN	A child psychotropic prescription is justified by a clear target, a developmental formulation, a proportionate place in the plan and an accountable review process.
DEVELOPMENTAL PHARMACOKINETICS AND PHARMACODYNAMICS IN CHILDREN	In child psychopharmacology, developmental physiology changes the path from prescribed amount to clinical effect, so dose, concentration and response must never be treated as interchangeable.
STIMULANTS IN CHILDREN	Stimulant safety follow-up is longitudinal: periodically record physical parameters, review real-world function, and investigate new concerns before deciding what they mean.
ANTIPSYCHOTICS IN CHILDREN	An antipsychotic prescription for a child is complete only when its target symptom, indication-specific scope, and metabolic monitoring plan can all be read from the clinical record.
ANTIDEPRESSANTS IN CHILDREN	Write the whole regimen sentence: medicine, child population, indication, start, schedule, titration, target, and ceiling statement.
MOOD STABILIZERS IN CHILDREN AND ADOLESCENTS	For paediatric mood stabilisers, the safe answer is the whole regimen: indication, population, dose pathway, ceiling, and monitoring - never the milligram figure alone.
MONITORING AND CONSENT ISSUES IN CHILD PSYCHOPHARMACOLOGY	Monitor the medicine, the child's functioning, and the family's understanding; consent is a continuing clinical conversation, not a form completed before treatment begins.

ASK	HOLD
OFF-LABEL PRESCRIBING, DOSING PRINCIPLES AND START-LOW GO-SLOW IN CHILDREN	Off-label prescribing in children is justified by an explicit individual rationale, transparent discussion, conservative initiation, gradual titration, and review against a pre-defined target.
ASSESSMENT AND RATING TOOLS	
PRINCIPLES OF CHILD PSYCHIATRIC HISTORY AND EXAMINATION	A child psychiatric assessment is credible when developmental history, direct mental-state observation and collateral accounts are integrated without allowing any single source to stand for the child.
PLAY ASSESSMENT AND INTERVIEWING CHILDREN	Use play to open and observe the child's world; use corroboration to decide what the observation means.
DEVELOPMENTAL AND IQ TESTS	Choose the test by the question, interpret the child's performance in context, and never let a score do more clinical work than the assessment can support.
ADAPTIVE AND DEVELOPMENTAL SCREENING	A developmental or adaptive screen is useful only when its pattern is interpreted in context and used to decide the next clinical step.
BROAD-BAND RATING SCALES	A broad-band rating scale is most useful when its score is interpreted as one informant's structured account within a full clinical formulation.
PROJECTIVE TESTS IN CHILDREN	Projective tests can deepen a child assessment only when their observations are kept tentative, explored with the child, and corroborated elsewhere.
MULTIAXIAL AND MULTI-INFORMANT ASSESSMENT IN CHILD PSYCHIATRY	Multiaxial formulation preserves the distinction between symptoms, context, physical health, development, and disability so that clinical planning addresses the whole child.
NEUROPSYCHOLOGICAL ASSESSMENT OF CHILDREN	Neuropsychological assessment is most useful when it explains a functional difficulty through a coherent cognitive profile and turns that explanation into supports that can be tested in the child's real environment.
THERAPEUTIC INTERVENTIONS	
PLAY THERAPY	Play therapy is a formulated therapeutic relationship in which play helps the child express, explore and work through difficulty; the therapist follows or directs the medium only as the clinical task requires.
BEHAVIOUR THERAPY AND PARENT MANAGEMENT TRAINING IN CHILDREN	Formulate the sequence, strengthen the behaviour you want repeated, and help caregivers respond predictably enough that escalation no longer becomes the easiest route out of conflict.
FAMILY THERAPY AND FAMILY INTERVENTIONS IN CHILD PSYCHIATRY	Family intervention changes the conditions around a child's difficulty by helping the family see, test, and sustain a safer and more workable pattern of care.
COGNITIVE BEHAVIOUR THERAPY AND ADAPTATIONS FOR CHILDREN AND ADOLESCENTS	Developmentally adapted CBT keeps the formulation and therapeutic aim intact while changing the route by which the child can understand, practise and own the work.

ASK	HOLD
SPECIAL EDUCATION AND REMEDIAL AND EDUCATIONAL INTERVENTIONS	The educational prescription is complete only when it names the barrier, the support, the responsible partner and the route for review.
EARLY INTERVENTION AND STIMULATION PROGRAMMES	Early intervention succeeds when a child gains meaningful participation through repeated, enjoyable opportunities that caregivers can realistically sustain.
EPIDEMIOLOGY, SERVICES AND NATIONAL CONTEXT	
EPIDEMIOLOGY OF CHILD PSYCHIATRIC DISORDERS IN INDIA	In India, cite the NMHS adolescent result only with its age and sampling limits; for younger children, state plainly that an all-India psychiatric prevalence figure is not established.
SCHOOL MENTAL HEALTH PROGRAMMES AND LIFE-SKILLS EDUCATION	School mental health succeeds when life-skills teaching, a supportive school climate and a clear route to clinical or protection services work as one system.
RASHTRIYA BAL SWASTHYA KARYAKRAM (RBSK) AND THE 4DS	RBSK uses the 4Ds to identify childhood health concerns and link them to care; the psychiatrist turns a referral into an individual, developmental and family-centred plan.
INTEGRATED CHILD DEVELOPMENT SERVICES AND CHILD MENTAL HEALTH POLICY IN INDIA	Anganwadi Services are an integrated child-development platform whose mental-health value lies in contextual observation, caregiver partnership and a reliable bridge to appropriate care.
CHILD PROTECTION, ABUSE AND JUVENILE JUSTICE	
TYPES OF CHILD ABUSE	Child maltreatment is best understood as harm or threatened harm within a relationship of responsibility, trust or power: name the pathway - physical, sexual, emotional, neglectful or exploitative - then formulate the child's whole experience.
CLINICAL FEATURES AND INDICATORS OF CHILD ABUSE	Clinical indicators of abuse require recognition, not premature conclusion: preserve the finding, test the explanation, hear the child, and keep uncertainty explicit.
CHILD SEXUAL ABUSE ASSESSMENT AND PSYCHIATRIC SEQUELAE	In suspected or disclosed child sexual abuse, the psychiatrist listens carefully, assesses safety and psychiatric need, documents source and uncertainty, and does not turn clinical care into a repeated forensic interview.
POCSO ACT 2012	In India, mandatory reporting under POCSO is a legal duty: any person with apprehension or knowledge must inform the designated police authority, and failure to report is punishable.
MANAGEMENT AND INTERVENTION IN CHILD ABUSE CASES	In child abuse management, protect the child first, coordinate the adults and services around the child, and use trauma-focused intervention for the child's current clinical needs.
JUVENILE JUSTICE (CARE AND PROTECTION OF CHILDREN) ACT 2015	The Juvenile Justice Act separates an alleged offence from a child's vulnerability, and a psychiatric opinion assists the statutory forum without replacing it.

ASK	HOLD
CHILD IN CONFLICT WITH LAW AND CHILD IN NEED OF CARE AND PROTECTION	Child in conflict with law concerns an alleged act; child in need of care and protection concerns vulnerability and the need for safe care.
CHILD LABOUR AND ADOPTION	Child labour and adoption are formulation contexts: assess the child carefully, protect safety, and work with the meanings and relationships around the child without turning context into diagnosis.
BULLYING AND ITS MENTAL HEALTH CONSEQUENCES	Bullying is defined by intentional, repeated harm and a power imbalance; when it is disclosed, assess its psychiatric impact and current safety rather than treating it as routine peer conflict.

References

Every specific in this chapter is bound to one of the sources below, and the count is the number of claim rows each carried. 29 of those rows are statutory and were read at the primary Act on India Code rather than from any textbook's summary of it, because a stale or paraphrased section changes what a clinician is legally obliged to do. Doses were read at current regulatory labelling, and each carries its own source receipt naming the regulator, the product, the label version and the retrieval date. 6 row(s) are recorded at partial confidence and 2 as a declared gap: a declared gap is a correct answer here, and no number has been supplied to fill one. The must-have-papers cross-check was NOT performed for this Paper III chapter, because the paper lists do not yet exist in the intel index; for Paper III the topic bank plus the syllabus scaffolding is the completeness authority. This table records provenance, not proof: it says where each specific came from, not that the chapter's prose uses it correctly, which the content pass and the ship review test.

PAPER III

Mental health legislation and forensic psychiatry

Eight bands . one complete notes document

Orientation: mental health law and the forensic questions

1 · Orientation: mental health law and the forensic questions

Why these marks are here. Mental health law and forensic psychiatry is the one part of the paper that asks you to reason as a clinician and as a party to the legal system in the same breath. On the wards you already work inside a statute book that decides whom you may admit, what you may treat, and how far your authority reaches; and every so often a court reaches into that clinical world and puts a question only a psychiatrist can answer - was this act excused, is this person competent to this particular legal step, is this patient a risk the law must weigh. Candidates lose marks here less because the material is obscure than because the two worlds are usually taught apart, are easy to confuse under time pressure, and turn on fine distinctions that are either read straight from the statute or badly reconstructed from a half-remembered lecture. What this opening section gives you is the chapter's advance organizer: a single map to carry in your head, so that each later provision arrives as a marked place on ground you already hold rather than as one more law to be memorised in isolation.

The map has one shape, and fixing it is worth more than any single provision. The chapter runs on two spines, with one idea threaded down the length of both. The first spine is legislation, the statutes you operate inside; the second is the run of forensic questions a court reaches in to ask; and the idea beneath both is **capacity** - whether a particular person, faced with a particular decision, at a particular moment, could do the thing the law asked of them. Every statute in the chapter is worked from its own enacted text rather than from a summary, because a paraphrase drifts and a digest goes out of date; and one of those texts has been recodified recently, which makes the currency of a citation itself an examinable point. Hold the two spines, look for the capacity under whatever question sits in front of you, and the topics that follow stop competing for memory and begin to reinforce one another.

Inside	Across	Beneath
THE LAW YOU PRACTISE WITHIN	THE QUESTIONS A COURT ASKS	CAPACITY, THE SINGLE IDEA

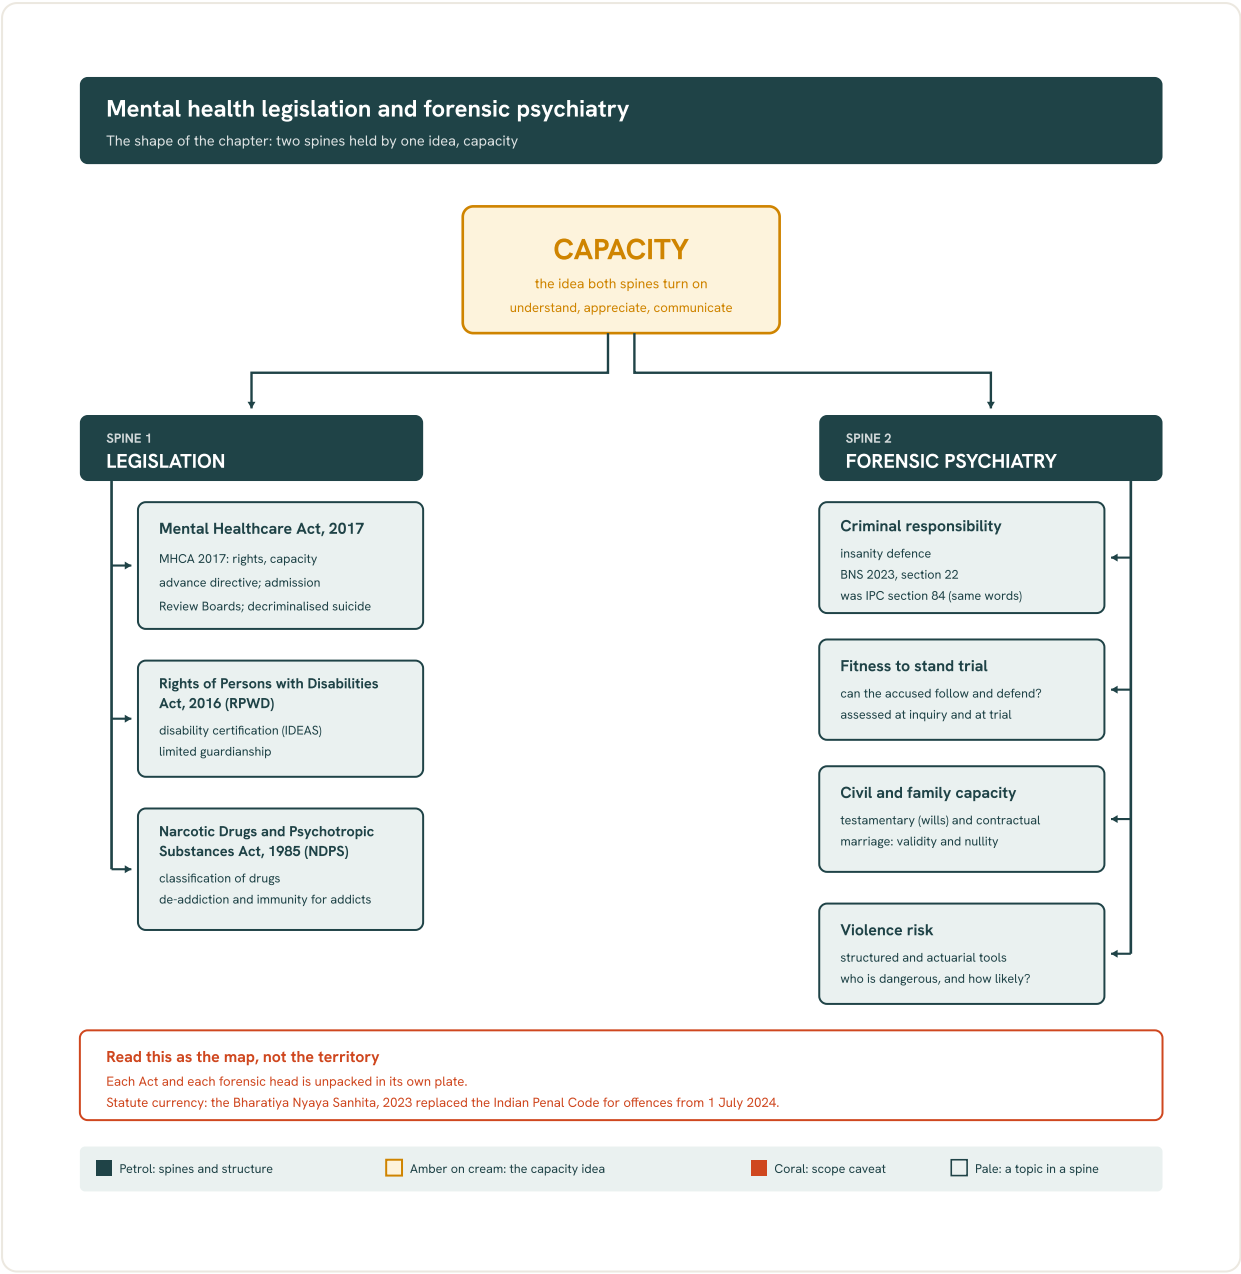

Fig 25.1. The chapter runs on two spines. Legislation (the Mental Healthcare Act 2017, the RPWD Act 2016 and the NDPS Act 1985) sits on one side, and the forensic questions of criminal responsibility, fitness to stand trial, civil and family capacity, and violence risk on the other. Both turn on a single organising idea, capacity, so read this as the shape of the chapter and study each head in its own plate.

1.1 The whole chapter on one map

Read as a flat list, the mental health legislation, the disability law, the narcotics law, the tests of criminal responsibility, the several civil and family capacities and the assessment of violence risk look like unrelated statutes to be learned in parallel, each with its own numbers to be crammed. They are not unrelated. They sort into two columns - the law a psychiatrist works within, and the questions a court puts from outside - and one construct runs down both columns and ties them together. Seeing this before any single provision is not decoration: it converts memorising into placement, and a new rule is learned far faster when there is already a labelled slot waiting to receive it.

The table below sets the two spines against shared axes so the parallel is visible at a glance. It teaches no rule of its own, and every provision it names is developed in the section that owns it.

The accompanying figure carries the same map in a single view, to keep beside the text as the picture the words are describing.

SPINE	WHAT IT IS	THE QUESTION BENEATH IT	WHERE THE PSYCHIATRIST MEETS IT
First spine: legislation	The statutes you practise inside - the Mental Healthcare Act, the Rights of Persons with Disabilities Act and the narcotics law	May I admit, treat and protect this person, and on what lawful authority	On the ward and in the clinic, and in the certificates the law asks you to sign
Second spine: forensic	The questions a court reaches in to ask - about responsibility, civil and family competence, and risk to others	Was this act excused, is this person competent to this legal act, is this patient a danger the law must weigh	In the report to the court and in the witness box, on the court's timetable rather than the clinic's

1.2 The first spine: the law you practise inside

The first spine is the **mental health legislation** a psychiatrist works within, and its centre of gravity is the Mental Healthcare Act. What makes the Act the natural opening of the whole chapter is that it is **rights-based** and capacity-based rather than custody-based: it starts from the person's rights and their ability to decide, and builds its powers of admission, treatment and protection on that foundation, instead of around a bare power to detain. Its definition of illness, its consent and admission machinery, its review boards, its authorities, and its limits on procedures such as electroconvulsive therapy and restraint are each taught in their own place. For the map it is enough to see that all of them descend from the same rights-and-capacity root, which is why a question on any one of them can be reasoned toward from that root when the exact section will not come.

Two further statutes stand beside it. The disability legislation, the Rights of Persons with Disabilities Act, recognises mental illness among the disabilities it protects and carries its own machinery of certification, benefit and guardianship - a logic aimed at inclusion and entitlement rather than at treatment, and therefore a different instrument doing a different job. The third is the narcotics law, which this chapter reads purely as law: how it classifies controlled substances, how it scales its penalties, and what it provides for treatment and for immunity. The clinical management of dependence and its de-addiction belongs to another chapter and is named at the border below. What unites the three is that each is an instrument you operate from the inside, not a question put to you from without.

IN INDIA

Every statute in this chapter is an Indian primary Act, and you are examined on the Indian book, not on a Western framework a general textbook might describe. The Mental Healthcare Act is rights-based and capacity-based by deliberate design, a clean break from the older custodial model; the disability and narcotics statutes are likewise Indian instruments, with Indian thresholds and Indian certifying authorities. One of the criminal statutes has moreover been recodified recently, so a candidate working from an older text must confirm that the provision cited is the one currently in force. Reading each Act from its own words, and checking that those words are still the law, is the whole discipline the chapter rewards.

1.3 The second spine: the questions a court asks

The second spine is **forensic psychiatry** proper: not a body of statute you practise inside, but a set of questions the law reaches in to ask, to which your clinical assessment is the answer it needs. They gather into three families. The first is **criminal responsibility** - whether unsoundness of mind at the time of an act should excuse it - together with the neighbouring questions of fitness to stand trial, of diminished responsibility and automatism, of the legal concepts of intent, of the legal standing of deception-detection methods, and of the detection of malingering. The second is civil and family capacity - whether a person is competent to make a will, to enter a contract, to marry or to be divorced, to keep custody of a child, to manage property, or to be certified fit for work. The third is the assessment of violence risk - how dangerousness is conceived, and how the risk of future violence is estimated, by structured clinical judgement and by actuarial method.

These are questions with forums and timetables that are not the clinic's. The court sets the question, fixes the moment at which it must be answered, and receives the answer as evidence rather than as treatment - which is why a forensic opinion is written and defended quite differently from a ward note, and why the audience for it is a judge and not a patient. Where a forensic question brushes against child law - the protection of a child, or a juvenile in conflict with the law - the governing statutes are taught in another chapter and are only named, at the border below. The ethics of giving evidence, the confidentiality owed, and the certification of a report for a court are a subject of their own, and are placed with their own chapter below. This chapter keeps the clinical questions; it does not absorb the statutes and the professional duties that neighbour them.

1.4 Capacity: one idea seen from many benches

Why one construct carries the whole chapter. The reason the two spines belong in one chapter, rather than in two, is that a single question sits beneath almost every topic on either of them. Whether the setting is a ward or a courtroom, the law is finally asking whether a specified person could make a specified decision. On the legislation spine it asks in order to protect and to empower - may this person decide their own treatment, and if not, who decides for them and how. On the forensic spine it asks in order to attribute or to withhold - may this person be held responsible for what they did, may this will stand, may this marriage be undone. The asking is the same act in different robes, and once that is seen the chapter reads as one subject rather than as a dozen.

Capacity in this sense takes a recognisable set of forms, each a full topic in its own right and each owned and taught in its own place. It is worth naming them here, as a set, precisely so that you meet each later one as a member of a family you already recognise:

- the capacity to consent to treatment, under the mental health legislation;
- the capacity to make a valid will, the testamentary capacity;
- the capacity to enter a binding contract;
- the capacity to be held criminally responsible for an act;
- and the capacity to stand trial, the fitness to plead.

Two properties make this family behave as it does, and the chapter's cross-cutting synthesis draws them out in full where it is owned. Capacity is **decision-specific**, so the same person may hold it for one decision and lack it for another at the very same moment; and it is **time-specific**, so it is judged as at a fixed instant - the time of the act, the time of the will, the time of the trial - and can change between one moment and the next. The work of this opener is only to plant that idea; the individual tests, and the grid that contrasts them, are developed where they are owned and are not restated here.

TRAP **Treating capacity as a single global switch a person either has or lacks.** The examiner watches for the candidate who writes that a patient "lacks capacity" full stop, or who reads one capacity off another - competent to consent, therefore competent to make a will. Capacity is asked of a named decision at a named moment. An opinion that omits the decision or the moment is not an incomplete opinion but no opinion at all, and every individual test in this chapter is built to be applied to one decision, at one moment, at a time.

1.5 Every statute from its primary source, and why currency now matters

The habit that separates a reliable answer from a merely plausible one is reading each statute from the **primary source** - the Act as enacted - rather than from a secondary summary, a coaching note or a half-remembered lecture. A paraphrase softens the exact word the law turns on; a summary drops the proviso that decides the hard case; and a textbook written a few years ago may faithfully describe a provision that has since been amended or replaced. This chapter therefore works every statute from its own text, quotes the operative words where they carry the point, and treats the precise wording, not the gist of it, as the thing to be learned.

RULE **Read the law from its primary source, and find the capacity beneath the question.** Two habits carry this chapter: go to the Act itself for the words that decide a point, and, when a question empties your head, ask which spine it sits on and which capacity lies under it. The first keeps your citation accurate; the second keeps your reasoning organised when the exact section will not come to you cold.

Currency is part of that same discipline, and it is why the substantive criminal law of this chapter now needs particular care. The long-standing penal code has been recodified into a new statute, and the insanity exception, together with the rule that places the burden of proving it, have moved with it into the new penal code and the new law of evidence, carried across in substance

rather than rewritten from scratch. The new code's own transition provisions decide which text actually governs a given case: the recodified provision applies to an offence committed on or after the recodification's commencement date, while the superseded provision remains the operative law for an offence committed before that date and for a proceeding already pending when the new code commenced, because the new code expressly saves it for that purpose. An answer forfeits the currency mark when it cites a provision that does not govern the offence or proceeding in front of it, in either direction; it does not forfeit the mark for correctly citing the superseded provision to a case the savings clause keeps under it. The precise sections, the effective date, the savings provisions, and the names of the current and the historical provisions are taught where the criminal-responsibility topic owns them; for the map, the only point is that the citation must match where the offence or proceeding actually falls.

PITFALL

The recurring real-world error is citing whichever provision does not govern the case at hand - reciting the recodified section for an offence committed before its commencement date, or reciting the superseded section for an offence or a proceeding the new code has already moved forward, or stating an immunity or a presumption without the conditions the statute attaches to it. The wording of the insanity exception survived its recodification almost unchanged, so the doctrine usually survives the slip; the citation does not, and an opposing advocate who spots a report resting on the wrong side of that line has an easy way to weaken the witness before a word of substance is heard. Confirm which provision the offence date or the proceeding's pendency actually selects, then cite it.

1.6 What is named here and taught elsewhere

A map is as much its borders as its interior, and four subjects a reader might reasonably expect to find in a law-and-forensic chapter are deliberately kept outside it, named at the edge and cross-referred so that the pointer is never lost. Each belongs to a chapter that teaches it in full, and the reason to keep them out is that answering a border question with the neighbour's material is one of the commonest ways to lose marks here:

- the child-protection statutes, including the provision for trying certain juveniles as adults, belong to the Child psychiatry: assessment, treatment, services and protection notes;
- forensic ethics, consent and confidentiality, the certification of a report for court testimony, and disaster and prisoner psychiatry belong to the Forensic ethics, consent and legal procedure notes;
- the clinical technique of electroconvulsive therapy and other neurostimulation belongs to the ECT and neurostimulation notes, while this chapter keeps only the statute's consent rules for it;
- and the clinical side of the narcotics law, the substance use disorders themselves and their de-addiction pharmacology, belongs to the Substance use disorders notes.

The boundary is not arbitrary, and the fitness-to-work certificate makes the logic plain. A single occupational-fitness certificate signed for an employer is this chapter's business; the report and

certificate written for a court are the forensic-conduct chapter's, because the duty owed and the audience addressed are different. Keeping these lines clean is itself examinable, and a candidate who can say where a topic stops has usually understood where it belongs.

1.7 Carrying the map into the hall

The value of an advance organizer is that it can be rebuilt from almost nothing when memory fails under pressure, and this one reduces to three phrases that regenerate the whole chapter between them.

MNEMONIC

Law inside, court across, capacity beneath

Rebuild the whole chapter from three phrases. **Law inside** is the legislation you practise within - the Mental Healthcare Act, the Rights of Persons with Disabilities Act and the narcotics law. **Court across** is the run of questions a court reaches in to ask - responsibility for an act, competence to make a will, to contract, to marry or to be tried, and risk to others. **Capacity beneath** is the one foundation carrying both, because each of those is finally a question of whether a particular person, for a particular decision, at a particular time, could do what the law asked of them. Recall the two spines, then the foundation under them, and the chapter reassembles itself from memory.

GOOD TO REMEMBER

When a legislation-or-forensic question empties your head in the hall, run the map before you panic. Ask which of the two spines the question belongs to, then find the capacity beneath it and name the decision, the moment and the forum the question is really about. That almost always surfaces the section, the test or the instrument you could not summon cold; and on the ward the same three-part habit - which decision, which moment, which forum - is what keeps a real opinion from being quoted later for a question it never actually answered.

Read the chapter now with the map already in place, and each statute and each test arrives as a named location rather than a loose fact. The detail - the sections, the durations, the criteria, the cases and the instruments - is taught, and cited to its source, in the topics that own it. What this opener leaves you with is the frame those details hang on.

This chapter has two spines, the law you practise inside and the questions a court asks, held together by one idea, capacity: name the decision, name the moment, name the forum, and every section and test in the chapter finds its place.

The Mental Healthcare Act 2017

2 · Salient features and objectives of MHCA 2017

This is the statute a psychiatrist in India actually practises inside, and the examiner opens the whole law paper with it because everything downstream is a working-out of the reorientation

it announces. The Mental Healthcare Act, 2017 did not simply update the machinery of admission and licensing that had governed the field for a generation. It changed the question the law asks. Where the older regime asked how an unwell person could be taken into care and kept there, the new statute asks what rights that person holds and whether they retain the capacity to decide, and it builds every other mechanism around the answer. A candidate who grasps that single reversal can reconstruct most of the Act from first principles; a candidate who misses it will recite features without a spine.

The marks here reward two things done together: a precise statement of what makes the Act a **paradigm shift**, and the enactment facts that fix it in time and place. Salient features answered as a shopping list read thin, and objectives answered without the primary Act read as opinion. The safe answer reads the Act as a coherent design, names the enactment facts that pin it down, and shows why the design is what it is.

10 of 2017	7 Apr 2017	29 May 2018	30 Oct 2019
ACT NUMBER	PRESIDENTIAL ASSENT	BROUGHT INTO FORCE	UNION-TERRITORY EXTENSION

2.1 The paradigm shift: from custody to rights

The organising idea of the statute is that it is **rights-based** rather than custody-based. The law it replaced approached mental illness through the lens of confinement and management: its central acts were reception, detention and the appointment of someone to hold authority over the unwell person and their property. The person at the centre of that scheme was, in law, largely an object of decisions made for them. The current Act inverts that posture. It treats the person with mental illness as a **rights-holder** whose entitlements the State must protect and whose own will and preferences the system must seek before it overrides them.

Calling the Act rights-based is not decoration; it is a description of how the statute is engineered. A rights-based law starts from what is owed to the person and treats every power to act against their expressed wishes as an exception that must justify itself. The older **custodial** model ran the other way: the power to detain and treat was the starting point, and the person's objection was a problem to be managed. This is why an answer that lists admission categories and licensing rules, however accurate, misses the examiner's point. Those mechanisms exist in the new Act too, but they now sit downstream of a prior commitment to rights, and their whole shape is bent by it.

TRAP **The Act is a rights statute, not a rebadged custody-and-licensing law.** The commonest error is to answer "salient features" with a catalogue of admission routes and registration rules, as though the reform merely modernised its custodial-era predecessor. That misreads the question. The Act reorganises mental-health law around the person's rights and capacity, and the admission and licensing machinery is a consequence of that reorientation, not the substance of it. State the reversal first, then the features that flow from it.

2.2 Capacity and autonomy as the organising logic

If rights are the destination, **capacity** is the road the Act builds to reach them. The statute keys the lawfulness of acting for a person to whether that person has the capacity to make the

particular decision at hand, and it protects the person's **autonomy** by requiring that their capable choices be respected and that their earlier or represented wishes be sought when capacity is impaired. The precise legal test for capacity, and the definition of mental illness that sits beside it, are set out in full where this chapter treats the definition of mental illness and the capacity to make treatment decisions; the point to hold here is architectural rather than definitional. Capacity is the hinge on which the entire Act turns.

Two design consequences follow, and they are worth seeing as consequences rather than as separate features. First, decision-making about a person is meant to be **supported** before it is substituted: the law prefers helping a person to decide over deciding for them, and it provides instruments to make that support real. Second, when the system must act despite a person's wishes, it is meant to reach for the **least restrictive alternative** consistent with safety and care. Care becomes the default and coercion the guarded exception, and every coercive power in the Act carries conditions precisely because the design treats coercion as something to be justified and limited, never assumed.

A useful way to feel the size of the shift is to watch where the burden sits. Under a custodial law the unwell person effectively had to earn their liberty back: the authority to hold and treat them was assumed, and the onus lay on the patient to displace it. A capacity-based law moves that burden the other way. The person's decisional autonomy is the starting position, and it is the system that must show why a particular choice may be taken out of their hands rather than left with them. That inversion is what turns a catalogue of features into a rights statute, because it makes every power to act against a person's wishes answerable for itself rather than automatic.

RULE **The Act is built around capacity and autonomy: care is the default and coercion the guarded exception.** Read any provision by asking what it does to the person's decisional autonomy and how tightly it conditions any power to override it. Provisions that support the person's own decision are the rule; powers that substitute for it are exceptions hedged with conditions. That single lens organises the whole statute and is what the examiner is really testing.

2.3 The objectives: why Parliament enacted it

The objectives of the Act are best read against the pressures that produced it. India had bound itself to an international obligation to align its domestic law with a rights-based conception of disability, and the older custodial statute could not be reconciled with that conception. The Act is the instrument that closes the gap. Its preamble frames its purpose in the language of provision, protection and the fulfilment of rights, and the working objectives can be stated plainly:

- To protect, promote and fulfil the rights of persons with mental illness during the delivery of mental healthcare and services.
- To align domestic law with India's obligations under the international disability-rights framework, which the older custodial statute could not satisfy.
- To provide for mental healthcare and services and to regulate the establishments that deliver them, so that care meets a national standard.

Read together, these objectives explain the temper of the whole statute. It is simultaneously a charter of entitlements and a scheme of regulation: it tells the State what it owes the person, and it tells providers what they must meet. The rights language is not aspirational preamble that the operative sections then ignore; the operative sections are the machinery by which the objectives are meant to be delivered, which is why the objectives and the salient features are two views of the same design.

IN INDIA

India enacted this statute to bring its mental-health law into line with its obligations under the international disability-rights framework, retiring a custodial-era predecessor in favour of a rights-based scheme. Because public health is administered by the States, the Act sets a national floor of rights while the bodies that carry it - the health authorities, the review boards and the registered establishments - are stood up unevenly across the country. The distance between the right guaranteed on paper and the service available on the ground is therefore itself part of the Indian reality a psychiatrist works within, and a realistic answer acknowledges it rather than describing the Act as if it were fully operational everywhere.

2.4 Enactment, commencement and extent

Because this is a statute read from the primary Act, the enactment facts are examinable in their own right and are easy marks when stated exactly. The law is **10 of 2017** and it received the assent of the President on **7 April 2017**. Its commencement provision, section **1(3)**, is a two-limbed rule and its verbs matter: the Act shall come into force on such date as the Central Government may appoint by notification, or on the completion of **nine** months from the date of assent. The coming-into-force is mandatory; what is discretionary is only the choice of the appointed date.

In the event, the Central Government exercised that power and the Act was brought into force on **29 May 2018** by notification, well past the nine months from assent that the alternative limb described above would otherwise fix; this chapter flags that gap between the statutory text and the notification record as an anomaly rather than resolving it. Its extent provision, section **1(2)**, applies the Act to the whole of India; the reach was later widened to the union territories of Jammu and Kashmir and Ladakh by a further notification. Keeping the extent point in view matters clinically, because it fixes the territorial scope within which the rights and duties the Act creates are enforceable.

The fallback commencement limb is not a technicality worth skipping over. Reform statutes are sometimes passed and then left unnotified, so that a law sits on the books yet binds no one because no commencement date is ever appointed. On its face, a nine-month fallback limb of this kind is meant to guard against exactly that hazard, an ambitious statute that a reluctant administration might prefer not to switch on; but the Act's actual commencement date on the official record runs past that nine-month mark, so the limb should not be taught here as an unqualified outer bound that was in fact honoured.

PITFALL

Reading the date of assent as the date the Act took effect. The Act received Presidential assent on **7 April 2017**, but it did not operate until it was brought into force by notification more than a year later. Citing the Act as effective from its assent, or loosely from its year of passage, mis-states the law that governed any event in the interval and confuses a mandatory duty to commence with the discretionary choice of when. It is exactly the kind of statute-currency error that a clinician giving evidence, and a candidate under examination, cannot afford.

2.5 The salient features as a single system

The features of the Act are best learned as expressions of the one design, each named for the right or value it serves rather than memorised as an unconnected list. The mechanics of each feature are developed in full in its own place in this chapter; what belongs here is the map that shows how they hang together. The accompanying survey sets each pillar beside the entitlement it delivers.

PILLAR OF THE ACT	WHAT IT ESTABLISHES	THE RIGHT OR VALUE IT SERVES
RIGHTS OF PERSONS WITH MENTAL ILLNESS	A statutory charter of enforceable rights during care	Dignity, non-discrimination, access to services
CAPACITY TO MAKE TREATMENT DECISIONS	Decisions keyed to the person's decisional capacity	Autonomy
ADVANCE DIRECTIVE	A means to record wishes ahead of a future loss of capacity	Prospective autonomy
NOMINATED REPRESENTATIVE	A personally appointed, or absent appointment, statutorily deemed or Board-appointed representative	Supported decision-making
ADMISSION CATEGORIES	Consent-led and safeguarded routes to inpatient care	Least restrictive care
MENTAL HEALTH REVIEW BOARDS	An independent body to oversee and adjudicate	Protection from arbitrary detention
MENTAL HEALTH AUTHORITIES	Registration and standards for establishments	Regulation and accountability
ATTEMPTED SUICIDE	Met as a matter for care rather than prosecution	Compassion over criminalisation
REGULATION OF COERCIVE TREATMENTS	Statutory control of electroconvulsive therapy, psychosurgery, restraint and seclusion	Protection from harm
PENALTIES FOR CONTRAVENTION	Defined consequences for breach of the Act	Enforceability

Two cautions attach to the last two rows. The Act sorts the regulated treatments into those it forbids outright and those it permits only under safeguards, and the placement of each into its category is set out where this chapter treats the prohibited and restricted procedures; the clinical

technique, dosing and mechanism of electroconvulsive therapy are not this chapter's at all and belong to the ECT and neurostimulation notes. Naming a feature is the work of this section; teaching its inner rules is the work of the sections that own it.

MNEMONIC

Rights, not custody; capacity, not status

The paradigm in one breath. The Act treats the person as a rights-holder rather than an object of custody, and capacity is a central organising principle for admission and treatment decisions rather than diagnostic status or another's authority, though some emergency, safety and prohibited-procedure provisions turn on their own statutory criteria, not on capacity. The directive written in advance, the representative the person nominates, the review boards and the regulation of coercive treatment are all consequences of those two reversals, not separate inventions.

2.6 The State's positive obligations

A distinctive feature of the Act, and one candidates routinely underweight, is that it does not only restrain the State from wronging the person; it obliges the State to act for them. A rights-based statute of this kind carries positive duties as well as negative limits, and the Act places several of them squarely on government:

- To provide mental healthcare and services and to work towards their availability and accessibility.
- To regulate mental health establishments through registration and enforceable standards of care.
- To reduce reliance on coercion by favouring supported decision-making and the least restrictive option.

These duties are what give the rights their teeth. A right of access to care means little without a State obligation to provide it, and a right against arbitrary detention means little without an independent body empowered to test detentions. The Act's ambition, then, is not merely to draw a boundary the State must not cross but to commit the State to a programme it must deliver, which is also the source of the reform's central practical tension, taken up below.

GOOD TO REMEMBER

On the ward the change is concrete. The opening question is no longer whether a person can be admitted and managed, but whether they have the capacity to decide, what they set down in any advance directive, and whom they nominated to speak with them. Default to the least restrictive option, record the capacity assessment in the notes, and involve the nominated representative early. The statute expects the person's own voice to be sought first, and the record is what shows that it was.

2.7 Currency, controversy and the implementation gap

The reform is genuine and the ambition is real, and the exam rewards seeing both the achievement and its unfinished edge. The central controversy is the distance between the rights

the Act guarantees and the services needed to honour them. A statute can declare a duty to provide care in a single clause; building the crisis services, the review boards and the trained workforce that discharge that duty is the work of years, and it proceeds unevenly because public health is administered by the States. The result is a law whose promise on paper outruns its delivery on the ground, and commentators reasonably ask whether a rights-based statute that is only partly resourced can secure the rights it names.

A second live point is one of currency at the statute's edges rather than its core. The Act sits alongside the wider disability-rights legislation and interacts with a criminal law that has since been recodified, so the exact provisions bordering the Act shift over time and are treated where those neighbouring laws are owned; this section flags that movement rather than settling it. What the Act itself decides is not in doubt, and that is what an answer should assert without hedging: a rights-based, capacity-based statute that reframes the person with mental illness as a rights-holder, keyed to capacity, defaulting to care, and conditioning coercion at every turn.

> The Mental Healthcare Act, 2017 is a rights-based, capacity-based statute that reframes the person with mental illness as a rights-holder: care is the default, coercion the guarded exception, and decisional capacity, not another person's custody, is a central organising principle across the Act's admission and treatment provisions.

3 · Definition of mental illness and capacity to make treatment decisions

Why the marks concentrate here. Two threshold questions decide everything the Mental Healthcare Act 2017 then does to a person: is this a **mental illness** the Act recognises at all, and does this person have the capacity to make their own treatment decisions. Every later power and protection in the statute - the advance directive, the choice of admission route, the consent to a treatment such as electroconvulsive therapy, the limits on restraint - hangs off these two definitions. Examiners return to them because they are compact, they are frequently misremembered, and each carries a cluster of traps that separate a candidate who has read the Act from one who is paraphrasing half a memory of it.

The difficulty is that both concepts sound familiar and are not what a clinician assumes. The definition of mental illness is not a list of diagnoses but a functional description with a deliberately drawn boundary, and where it draws that boundary - substance-associated conditions inside it, intellectual disability outside it - is exactly what is examined. Capacity is not a global attribute a patient either has or lacks; it is a rebuttable presumption, attached to a particular decision, tested against a short functional standard whose bare statutory wording surprises most readers. Alongside these sits a third provision that keeps the clinical determination of illness from being read as a legal verdict on the person.

2(1)(s)	3	4
MENTAL ILLNESS DEFINED	DETERMINATION OF ILLNESS	CAPACITY TO DECIDE

3.1 The definition of mental illness

The definition sits at section **2(1)(s)**, and its structure is worth dissecting rather than reciting, because the structure is where the reasoning lives. Mental illness means a substantial disorder of thinking, mood, perception, orientation or memory that grossly impairs judgment, behaviour, capacity to recognise reality or ability to meet the ordinary demands of life. Read it as two joined requirements. First, there must be a substantial disturbance in one of a named set of faculties - thinking, mood, perception, orientation or memory. Second, that disturbance must grossly impair one of a named set of functions - judgment, behaviour, the capacity to recognise reality, or the ability to meet the ordinary demands of life. A disturbance without gross functional impairment does not satisfy the definition, and impairment without an underlying substantial disorder does not either.

The Act has chosen a **functional** definition rather than a categorical one, and the choice is deliberate. It does not enumerate diagnoses, so it does not go out of date each time a classification is revised, and it does not turn on a label but on severity and consequence. Only a disorder grave enough to grossly impair one of those core functions satisfies the definition. This matters because the provisions expressly predicated on an established mental illness - the coercive powers as much as many of the safeguards - are reserved for illness of that gravity, and a milder disturbance that leaves judgment, behaviour, reality-testing and everyday functioning broadly intact is, by the Act's own words, outside the definition. The definition does not gate the Act as a whole: provisions built around suspected or self-perceived mental illness, taught in their own place elsewhere in this chapter, engage without waiting on that threshold. The word doing the heavy lifting is "grossly": the definition is built around gross impairment, not any impairment.

3.2 What the definition takes in, and what it keeps out

Two boundary rules inside the same definition are the most heavily examined lines in this topic, and they run in opposite directions. The definition expressly *includes* mental conditions associated with the abuse of alcohol and drugs. It expressly *does not include* **mental retardation**, which it describes as a condition of arrested or incomplete development of mind specially characterised by subnormality of intelligence. So substance-associated mental conditions are in, and intellectual disability, standing alone, is out.

Hold the direction of each, because candidates routinely reverse them. The inclusion of alcohol- and drug-related conditions means a person whose mental state is disordered in association with substance use falls within the Act's definition and may draw on its protections and be subject to its provisions; the clinical management of substance use disorders themselves is a separate subject, taught in the Substance use disorders notes, and is not the concern here. The exclusion of intellectual disability means that a person whose only condition is arrested or incomplete development of intelligence is not, by that fact, a person with mental illness for the Act's purposes. That exclusion is not a withdrawal of rights: the framework that recognises and certifies intellectual disability, and confers benefits and safeguards on that basis, is the disability legislation dealt with elsewhere in this chapter. The Act simply keeps the two constructs in separate boxes. A person with intellectual disability who also develops a substantial disorder of

mood or perception can, of course, have a mental illness on the ordinary meaning of the definition; what the exclusion denies is that subnormality of intelligence is itself the illness.

MNEMONIC

Substance in, subnormality out

The two boundary rules of the definition, in the order they trip candidates. A mental condition associated with the abuse of alcohol or drugs is **included**; mental retardation, a condition of arrested or incomplete development of mind characterised by subnormality of intelligence, is **excluded**. If you can only carry one line on this definition into the hall, carry the two directions.

TRAP **The definition includes substance-associated conditions and excludes intellectual disability - not the reverse.** Because addiction is so often spoken of as a "vice" and intellectual disability as a lifelong "mental" condition, candidates flip the two. The statutory text is explicit and settled: conditions associated with the abuse of alcohol and drugs are within the definition of mental illness, and mental retardation is expressly outside it.

3.3 How mental illness is determined

A definition needs a method of application, and section 3 supplies it. Mental illness *shall* be determined in accordance with such nationally or internationally accepted medical standards, including the latest edition of the World Health Organisation's International Classification of Diseases, as may be notified by the Central Government. The verb is mandatory and it anchors the clinical judgment to recognised diagnostic standards rather than to idiosyncratic opinion. The **determination of mental illness** is thus a disciplined exercise: the clinician works from accepted nosology, not from personal conviction about who is or is not ill.

The provision then does something a purely clinical statute need not do: it fences off the reasons that may *not* be used. A determination *shall not* be made on the basis of a person's political, economic or social status, or membership of a cultural, racial or religious group, or for any reason not directly relevant to that person's mental health status. Nor may it rest on non-conformity with the moral, social, cultural, work or political values or the religious beliefs prevailing in the person's community. And a past history of treatment or hospitalisation, by itself, is not a ground for determining that a person is presently or will in future be mentally ill. Each clause closes a historically abused route by which unpopular, eccentric or merely inconvenient people were declared ill. The section is, in effect, a bar against psychiatry being used as an instrument of social control, and its clauses are best learned as the specific abuses they were written to prevent.

- not political, economic or social status;
- not membership of a cultural, racial or religious group;
- not non-conformity with prevailing moral, social, cultural, work, political or religious values.

IN INDIA

This is a distinctively rights-based drafting choice and a deliberate break from the older custodial law. By tying determination to notified medical standards and to the current International Classification of Diseases, and by forbidding determination on social, cultural, religious or political grounds, the Act aligns Indian practice with an internationally recognised evidence base and writes the safeguard against misuse into the statute itself. For the practising psychiatrist the working discipline is simple: the record should show that a determination rests on recognised diagnostic criteria and on the person's mental health status, and never on their beliefs, conduct or standing in the community.

3.4 Mental illness is not unsound mind

The most consequential firewall in this whole topic is the rule that a clinical finding of mental illness is not a legal finding of **unsound mind**. The determination provision states it plainly: the determination of a person's mental illness *shall* alone not imply, or be taken to mean, that the person is of unsound mind, unless they have been declared as such by a competent court. The modal is mandatory and the effect is a hard separation of two spheres. Mental illness is a medical construct, determined by a clinician against accepted standards. Unsound mind is a legal status, and it can be conferred only by a court.

Why this earns its place is that the two are constantly conflated, to a patient's cost. A diagnosis does not, of itself, strip a person of the legal capacities that unsoundness of mind would affect. Whether a person is criminally responsible for an act, whether they are fit to stand trial, whether they can make a will or a contract or manage their property - these are decided on their own tests, by the appropriate legal process, and are set out elsewhere in this chapter; none of them follows automatically from a psychiatrist's determination that a mental illness is present. The clinician determines illness; the court, on the relevant legal test, determines unsoundness of mind and its consequences. Keeping the two apart is not a technicality but the point of the provision.

PITFALL

A recurring clinical and medico-legal error is to let a diagnosis do a court's work - to write or imply that because a person has a mental illness they are therefore of unsound mind, incompetent, or not responsible. The Act forbids that inference: determination of mental illness alone does not mean unsound mind unless a competent court has so declared. A report that slides from a clinical diagnosis to a legal conclusion about capacity or responsibility oversteps the clinician's role and misstates the law.

3.5 Capacity to make mental-healthcare and treatment decisions

This is the required core of the topic. Section **4** sets the test of **capacity to make** mental-healthcare and treatment decisions, and its architecture must be learned exactly. Every person, including a person with mental illness, *shall* be **deemed** to have capacity to make decisions regarding their mental healthcare or treatment if they have the ability to do the following:

- understand the information relevant to taking the decision on treatment, admission or personal assistance;
- appreciate any reasonably foreseeable consequence of a decision, or of a lack of decision, on treatment, admission or personal assistance;
- communicate the decision, by means of speech, expression, gesture or any other means.

Two features of that text are examined again and again, and both cut against the way capacity is usually taught. The first is the deeming clause. The Act does not ask the clinician to establish that a patient *has* capacity; it deems every person to have it, so the presumption runs in the patient's favour and it is incapacity that must be demonstrated. This is a rebuttable presumption of capacity, and the burden sits with whoever asserts that the person cannot decide. The second is the connector. In the bare statutory text the three abilities are joined by the disjunctive word "or", not by "and" - a wording that is identical across the authoritative sources of the Act and that differs from the familiar functional model of capacity, imported from other jurisdictions and general teaching, in which a person must understand, retain and weigh the information and then communicate a choice, all elements being required together. The Indian provision, read literally, lists three abilities and joins them disjunctively. Whatever the interpretive debate about how those limbs are best applied at the bedside, the examinable textual fact is that the statute uses three limbs and the word "or".

A third clause completes the picture and guards the presumption from a common abuse. A decision that others regard as inappropriate or wrong does not, by itself, mean the person lacks capacity. Capacity is about the *process* of deciding - understanding, appreciating consequences, communicating a choice - and not about whether the choice matches what the clinician or family would prefer. An unwise decision by a capacitous patient is still that patient's decision. The generous means-of-communication clause points the same way: a decision expressed by gesture or any other means counts, so a person is not treated as incapable merely because they cannot speak in the expected register.

RULE **Capacity is presumed, decision-specific and functional - it turns on the decision, not the diagnosis.** Every person, including a person with mental illness, is deemed to have the capacity to make mental-healthcare and treatment decisions, and that presumption is displaced only by showing, against the statutory abilities, that this person cannot make this decision now. A diagnosis does not rebut it, and a decision the team dislikes does not rebut it.

3.6 Capacity as the switch the rest of the Act turns on

The capacity test is placed early in the Act because it is the switch several later provisions depend on. Whether a person is admitted on their own request or on another's application, whether an advance directive lies dormant or comes into operation, and whether consent to a treatment such as electroconvulsive therapy can be given by the patient themselves - each of these begins by asking whether the person presently has the capacity to make the relevant decision. Physical restraint is not on that list: it is authorised on its own statutory conditions, tied to imminent and immediate harm and to psychiatrist authorisation rather than to the patient's capacity, and is

taught under prohibited and restricted procedures elsewhere in this chapter. Those provisions invoke this test and are taught in their own right elsewhere in this chapter; none of them redefines it. What must be carried across all of them is that capacity here is **decision-specific** and time-specific: a person may have capacity for one decision and not another, and may regain it as their state changes, so it is assessed for the decision in front of the clinician at the moment it must be made, not settled once and recorded as a global finding.

It is worth naming, without teaching them here, that this treatment-decision capacity is one of a family of capacities the law recognises - the capacity to make a will, to enter a contract, to be held criminally responsible, to stand trial - each decision-specific, each with its own test, and each examined in its own place in this chapter. The thread that runs through all of them, that capacity is asked of a particular decision at a particular time rather than of the person in general, is drawn together in this chapter's cross-cutting synthesis. For the Act's own purposes the point stays contained: the capacity this section defines is the one the definition of mental illness and the rest of the statute are built to serve.

3.7 Four statuses candidates merge, kept apart

The commonest way this topic is lost is by treating four distinct statuses as one. The definition, the determination, the capacity test and the legal status of unsound mind answer different questions, are settled by different actors, and carry different consequences. Setting them on shared axes shows why each must be cited to its own provision and why one cannot be read off another.

STATUS	WHAT IT ASKS	WHO SETTLES IT, AND HOW	WHAT IT DOES NOT IMPORT
Mental illness (the definition)	Is there a substantial disorder that grossly impairs a core function?	Set by the definition provision; substance-associated conditions in, intellectual disability out	Does not by itself mean incapacity or unsound mind
Determination of mental illness	Is this person, now, mentally ill on that definition?	A clinician, against notified national or international standards including the current International Classification of Diseases	May not rest on social, cultural, religious or political grounds, or on past treatment alone
Capacity to make treatment decisions	Can this person make this mental-healthcare decision now?	Presumed for everyone; rebutted only against the statutory abilities, decision by decision	Not rebutted by the diagnosis, nor by an unwise choice
Unsound mind	Is this person, in law, of unsound mind?	A competent court, on the relevant legal test	Does not follow automatically from a determination of mental illness

Read across the last column and the discipline is clear: nothing on this list is a licence to infer the next. Mental illness does not import incapacity; determination does not import unsound mind; and capacity, presumed for all, is displaced only for the decision actually in issue. A clinician who keeps these four apart, and cites each to its own provision, has understood not just the definitions but the design.

GOOD TO REMEMBER

Assess capacity for the specific decision in front of you, and start from the presumption that the patient has it. Document the determination of illness against recognised diagnostic criteria, and keep it separate from any statement about the patient's legal capacity or responsibility, which is not yours to pronounce. A refusal you consider unwise, made by a patient who can understand, appreciate the consequences or communicate the choice, is a capacitous refusal - not evidence of incapacity.

Mental illness is a substantial disorder grossly impairing a core function - substance-associated conditions included, intellectual disability excluded - determined against accepted medical standards; and every person, including a person with mental illness, is deemed to have the capacity to make mental-healthcare and treatment decisions, tested by the ability to understand, appreciate or communicate, a presumption that a diagnosis alone does not rebut.

4 · Rights of persons with mental illness under MHCA

Why the marks cluster here. Of everything the Mental Healthcare Act sets out to do, its catalogue of rights is the part an examiner can turn into a one-line question and the part a clinician answers for on every ward round. The statute rewrote the relationship between the psychiatrist and the person in their care: where the earlier, custodial legislation treated the patient largely as an object of detention and management, this Act makes the same person the bearer of enumerated, enforceable rights that the appropriate Government, the mental health establishment and the treating professional are all bound to honour. To know these rights is to know the spine of the whole Act, because admission, treatment, the advance directive and the review machinery all exist to give them effect.

Fig 25.2 The Mental Healthcare Act 2017 is rights-based: the person with mental illness holds enforceable rights, and government, establishments and professionals carry corresponding duties. Admission and treatment mechanisms exist to give those rights effect.

The rights are gathered in Chapter V of the Act, and reading them at origin rather than from a summary is what separates a safe answer from a vague one. Two features organise the entire chapter. First, every right is written in the mandatory voice: the person shall have the right, never may, so each clause is a duty and not a discretion. Second, each right is a duty placed on a named actor, and identifying that duty-bearer is often the real content of the question.

4.1 A rights-based statute: the architecture of Chapter V

Chapter V does not create rights in the abstract. It follows a person from the door of the service to the ward and back into the community, attaching a duty at each step: a right to reach care at all, a right not to be warehoused once well, a right to be treated decently while admitted, a right to be treated as the equal of a person with a physical illness, a right to know what is happening, and a right to have it kept private. The examiner's favourite move is to give the guarantee and ask for

the section, or to give the section and ask whose duty it creates, so the map below is worth holding whole before the detail.

RULE **Every entitlement in this chapter is a mandatory duty, not a courtesy the service extends.** Each clause is drafted with "shall", which binds the appropriate Government, the establishment and the individual professional; a right the service could grant or withhold at will would not be a right. When you answer, name the guarantee, the section that carries it and the actor on whom the duty falls, because the mark usually sits in the duty-bearer, not the slogan.

RIGHT	SECTION	CORE GUARANTEE	WHOSE DUTY
Access to mental healthcare	Section **18**	Affordable, good-quality, sufficient, geographically reachable, non-discriminatory care from Government-run or funded services	Appropriate Government
Community living	Section **19**	To live in and not be segregated from society; not to be detained merely for want of family, home or community facilities	Government and establishment
Protection from cruel, inhuman and degrading treatment	Section **20**	To live with dignity, with enumerated protections inside the establishment	The establishment and its staff
Equality and non-discrimination	Section **21**	Parity with physical illness across all healthcare, including insurance	Providers and every insurer
Information	Section **22**	Understandable information on admission, review, illness and treatment	The treating team
Confidentiality	Section **23**	Confidentiality of mental and physical health information, with defined exceptions	All health professionals

18	21	23	3
ACCESS TO CARE	INSURANCE PARITY	CONFIDENTIALITY	CHILD WITH MOTHER

4.2 The right to access mental healthcare

The chapter opens with its most ambitious guarantee. Every person shall have a **right to access mental healthcare** and treatment from services run or funded by the appropriate Government. The Act does not leave "access" as a slogan; it defines its content. Care must be affordable, of good quality, available in sufficient quantity, geographically accessible so that a person need not travel

unreasonably far, and provided without discrimination on any ground. A service that exists only in a distant city, or only for those who can pay, does not satisfy the section even if what it offers is excellent.

The section does not stop at principle; it adds concrete, enforceable promises. A minimum range of mental health services is to be available in every district, which is the statutory hook for decentralised, district-level care rather than a handful of state asylums. Persons who are below the poverty line, destitute or homeless are entitled to treatment free of charge, so poverty may not be the reason a person goes untreated. And medicines on the Essential Drug List are to be provided free of cost from Community Health Centres upwards, which matters directly for the person on maintenance antipsychotic or mood-stabiliser treatment who would otherwise default for want of money.

The clinical significance is that this section reframes treatment from charity to entitlement: the person does not petition for care, the State owes it. Its honest limit, and a fair examination point, is that a positive socio-economic right of this kind is only as real as the budget and the workforce behind it, which is where Indian implementation is still catching up with the text.

4.3 The right to community living

Every person with mental illness shall have a **right to community living**: to live in, be part of and not be segregated from society. The section's sharpest clause is the one an examiner loves, because it targets a real and documented abuse. A person shall not continue to remain in a mental health establishment merely because they do not have a family, are not accepted by their family, are homeless, or because there are no community-based facilities to receive them. Clinical readiness for discharge is not to be defeated by a social problem; want of a home is not a psychiatric reason to detain.

To make the right achievable rather than aspirational, the Government is to support less restrictive, community-based establishments such as half-way homes and group homes, so that a person who no longer needs hospital care has somewhere to go. This is the statute's embrace of deinstitutionalisation and of care in the least restrictive setting, and it is the natural counterpart to the access right: one gets the person into care, the other stops that care from hardening into indefinite custody.

IN INDIA

The community-living right collides with a long-standing reality. Government mental hospitals still hold long-stay residents who are clinically fit for discharge but have nowhere to go, and community facilities such as half-way homes and supported accommodation remain scarce and unevenly distributed. District-level services under the national and district mental health programmes are the intended delivery route for both the access and the community-living guarantees, and the distance between the words of the sections and the services actually available on the ground is itself a favourite discussion question.

4.4 Protection from cruel, inhuman and degrading treatment

This section begins with a simple, powerful statement: every person with mental illness shall have a right to live with **dignity**, and shall be protected from cruel, inhuman or degrading treatment in any mental health establishment. It then refuses to leave "dignity" undefined and spells out what it means in the daily life of an admitted person: a safe and hygienic environment with adequate sanitation; access to leisure, recreation, education and the practice of religion; privacy; proper clothing and the right to wear one's own clothes; freedom from being forced to work, with appropriate remuneration where work is undertaken; freedom from compulsory tonsuring, that is forced head-shaving; and protection from all physical, verbal, emotional and sexual abuse.

Read against the history of custodial care in India, the chaining, the seclusion, the neglect and the stripping away of ordinary human texture that repeated inquiries have documented, each of those guarantees is an answer to a specific, remembered wrong. The protections candidates most often overlook are the most telling: the bar on forced labour without remuneration, and the bar on compulsory tonsuring. Both mark the line between a hospital and a place of confinement, and both were written in precisely because they had been ignored.

4.5 Equality, non-discrimination and the insurance-parity clause

Every person with mental illness shall be treated as the equal of a person with physical illness across the whole provision of healthcare. This **equality and non-discrimination** right forbids discrimination on grounds such as gender, sex, sexual orientation, religion, culture, caste, social or political beliefs, class and disability, and it demands emergency services, ambulance services and living conditions of a quality equal to those provided for physical illness. A protective clause adds that a young child shall ordinarily not be separated from a mother who is receiving care, preserving the mother-infant bond wherever it can be preserved; the section fixes that protection at a child below **three** years of age.

The clause that decides the mark. Set within the same equality section is the provision examined more than any other single line in this chapter: every insurer shall make provision for medical insurance for the treatment of mental illness on the same basis as is available for the treatment of physical illness. This is the statutory **mental health parity** mandate, and it is a mandatory "shall", not a recommendation. It is the clause that ended the routine exclusion of psychiatric illness from health insurance, and in practice it prompted the insurance regulator to direct insurers to bring their products into line.

TRAP **Candidates list the rights and forget that insurance parity lives inside the equality section.** The parity mandate is not a separate consumer-protection statute and it is not discretionary; it is a "shall" sitting within the non-discrimination right. That is exactly why an examiner can ask which provision made insurance cover for mental illness compulsory and watch half the room reach for the wrong chapter, or downgrade a binding duty into a mere recommendation.

4.6 The right to information

A person with mental illness, and their nominated representative, shall have a **right to information**. The pairing is deliberate: the person and the nominated representative hold the right together, because the section anticipates that a very unwell person may not be able to take everything in at the moment of admission. What must be disclosed is set out plainly. The person is entitled to be told the provision of law under which they have been admitted and the criteria for admission under that provision; their right to apply to the Mental Health Review Board for a review of that admission; and the nature of their illness together with the proposed treatment plan, including the treatment proposed and its known side effects. All of this must reach the person in a language and form they can actually understand.

The section then closes a familiar loophole. If full information cannot be given at the time of admission because the person cannot yet receive it, it must be provided promptly once they can, and it must be given to the nominated representative immediately in the meantime. The information right is therefore the practical substrate of informed consent and of the Act's separately defined test of the capacity to make mental-healthcare decisions: a person cannot exercise a treatment choice, or challenge a detention, on facts that have been withheld from them. The appointment and duties of the nominated representative, and the composition and powers of the Review Board, are provisions in their own right and are described elsewhere in this account of the Act.

> **GOOD TO REMEMBER**
>
> The information right is discharged, and defensible, only if it is documented. Record that the admission provision and its criteria, the right to seek a Review Board review, and the treatment plan with its known side effects were explained, and in what language and form. Where the person could not take it in, note that the nominated representative was informed and that the person was told again once able. A treatment plan the patient cannot understand has not been disclosed within the meaning of the section, however carefully it was written.

4.7 The right to confidentiality and its lawful exceptions

A person with mental illness shall have a right to **confidentiality** in respect of their mental health, their mental healthcare, their treatment and their physical healthcare, and all health professionals providing that care shall have a duty to keep the information confidential. The examination trap is to stop at the duty and call it absolute. It is not: the section itself enumerates the circumstances in which the duty yields, and knowing those circumstances is the substance of the answer. Disclosure is permitted, on necessary and limited terms:

- release to the nominated representative so that they can discharge their functions;
- disclosure to other mental health or health professionals for the person's care and treatment;
- disclosure to protect any other person from a real risk of harm or violence, confined to the information necessary for that purpose;
- disclosure to prevent a threat to the person's life;

- on the order of the Review Board, the Central Authority, a High Court or the Supreme Court, or another statutory authority competent to make such an order; and
- in the interests of public safety and security.

The exception permitting disclosure to protect a third party from harm supplies statutory permission for a necessary, proportionate disclosure; the section does not itself impose a positive duty to warn or protect, and any such duty arising under another law or professional standard must be analysed separately. The ethical reasoning around when and how confidentiality may be breached for the safety of another, together with the wider consent and certification duties of the psychiatrist, belongs to the Forensic ethics, consent and legal procedure notes and is not rehearsed here. What this section settles is the legal permission and its boundary: the duty is the rule, the enumerated grounds are the only exits, and disclosure under any of them is confined to what the situation genuinely requires.

PITFALL

Opposite errors flow from misreading the exceptions. The first is treating confidentiality as absolute and refusing to disclose even when a person is at credible risk of harm, when the section positively permits the necessary disclosure. The second is breaching confidentiality without an enumerated ground, or disclosing far more than the risk requires, on the loose assumption that a psychiatrist may share freely with family or police. State the exception you are relying on, and release only what that ground needs; a duty repeated without its conditions is how both mistakes are made.

4.8 Making the rights real: representative, Review Board and the ward

Rights on paper need a route to enforcement, and the chapter builds one into its own text. The information right points the person to the Mental Health Review Board to have an admission reviewed; the confidentiality section names the Board and the higher courts as the bodies that can order disclosure. The Board is the forum in which these entitlements are made justiciable, and running alongside it is the nominated representative, the person's appointed or statutorily identified voice, who co-holds the information right and receives disclosures the person cannot yet take in. Neither of those is taught here, because each is a substantial topic on its own; the point to carry is that the rights of this chapter are not merely declared, they are given a person to speak them and a body to enforce them.

Chapter V does not end with the six rights read here. It continues with further entitlements that the same rights-based logic generates, among them restrictions on releasing a person's information to the media, access to one's own medical records, rights to personal contact, communication and visitors, and access to legal aid. The exact section numbers of those later rights sit outside the provisions read at origin in this topic, so they are named rather than numbered; the reader should simply know that the chapter is broader than the core it is usually examined on, and that its later sections extend the same principle of dignity and self-determination.

MNEMONIC

A CoDE I Confide

The run of core rights in order: **A**ccess to care, **Co**mmunity living, **D**ignity and protection from cruel treatment, **E**quality with insurance parity, **I**nformation, and **C**onfidentiality. Recovering the phrase recovers both the guarantees and the order in which their sections run through the chapter.

Read every clause of this chapter in the mandatory voice, because the Act says the person shall have each right: a right the State could grant or refuse at its own discretion would not be a right at all.

5 · Advance directive under MHCA (making, revocation, override)

Why this earns marks. The **advance directive** is the Mental Healthcare Act's clearest break from substituted decision-making. It lets a competent adult record, ahead of time, how they wish and do not wish to be cared for and treated for a mental illness during a future period in which they can no longer decide for themselves. The marks sit here because the directive is a compact cluster of sections that pulls in almost every other theme of the Act at once: the capacity that triggers it, the nominated representative named inside it, the Mental Health Review Board that is the exclusive first-instance forum able to set it aside, and the liability of the clinician who follows or departs from it. A candidate who keeps the making, the operation, the revocation and the override apart, and who cites the correct section for each, has shown they can read a statute rather than paraphrase it.

The recurring difficulty is that the phrase sounds absolute, as though a directive, once signed, governs the person whatever happens next. It does not. The Act deliberately provides distinct routes by which a directive can be displaced or changed, and telling them apart is the commonest place candidates and clinicians go wrong: the person's own decision while they still have capacity, the person's formal revocation, and an override granted by the Board on application. Each has its own actor, its own section and its own modal verb, and the gap between a discretionary power and a mandatory duty is exactly what is being examined.

5	8	11	13
MAKING	REVOCATION	BOARD OVERRIDE	CLINICIAN LIABILITY

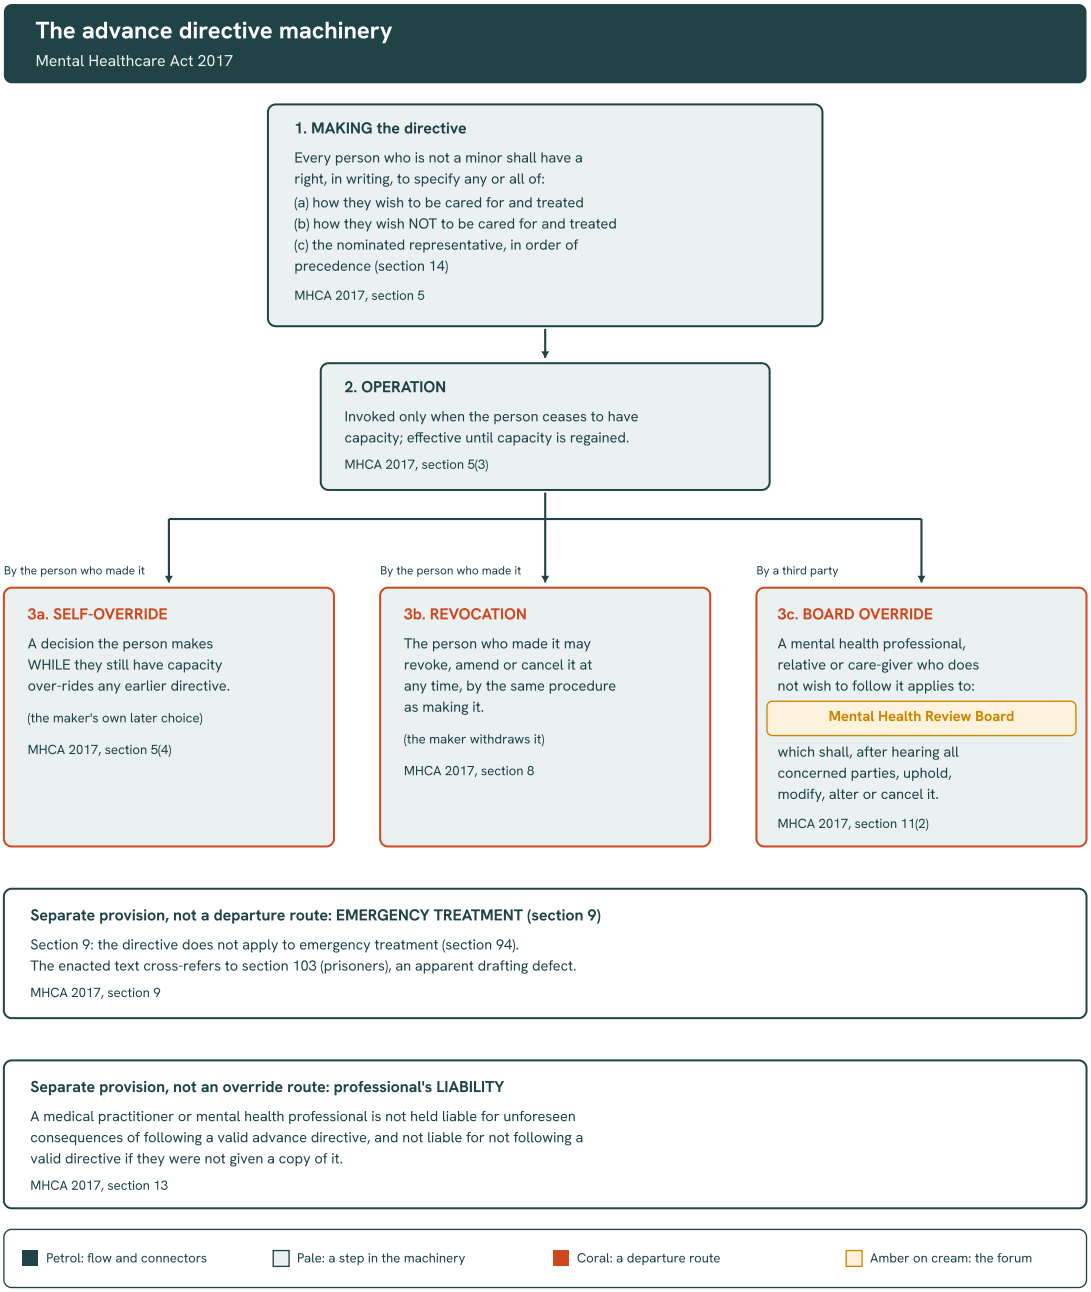

Fig 25.3. The advance directive under the Mental Healthcare Act 2017: every person who is not a minor shall have a right to make one in writing (section 5), it operates only once the person loses capacity (section 5(3)), and can be departed from by the maker's own later capacitous decision (section 5(4)), by revocation at any time (section 8), or by a Board override on the application of a professional, relative or care-giver, which the Board shall dispose of after hearing all concerned parties (section 11(2)). Separately, section 9 says the directive does not apply to emergency treatment; the enacted text cross-refers to section 103, though the Act's emergency-treatment provision is section 94 and section 103 concerns prisoners, an apparent drafting defect. Section 13 separately protects the professional from liability and is not an override route.

5.1 The right to make an advance directive

The right to make a directive is set at section 5. Every person who is not a minor shall have a right to make an advance directive in writing. The verb matters: this is a right conferred in mandatory terms, not a facility the establishment may extend at its discretion. What the directive may specify is stated in the person's own voice - the way they wish to be cared for and treated for

a mental illness; the way they wish not to be cared for and treated; and the individual or individuals, in order of precedence, whom they wish to appoint as their **nominated representative**. That last limb links the directive to the separate machinery of the nominated representative, whose appointment and duties this chapter treats in their own right; here it is enough that the directive is where the person may name, and rank, the people they trust to speak for them.

Beyond its contents, the making carries points that are commonly examined as one-liners. The right to make a directive exists irrespective of any past mental illness or past treatment: a history of illness neither bars a person from making a directive nor weakens one they have already made. The point is more than administrative. It refuses the assumption that a diagnosis, or a past spell of illness, strips a person of the standing to plan their own care; a directive made by someone with a psychiatric history is not thereby suspect, and the fact that a person was once unwell is not, by itself, a reason to look behind what they have set down. And a directive that is contrary to any law in force is **void ab initio** - void from the outset, not merely voidable later - so a directive cannot be used to demand something unlawful, and a clinician confronted with such a clause is not obliged to give it effect.

IN INDIA

Unlike an informal "living will," this is a statutory right of every adult who is not a minor, and it is enforceable: a clinician who sets aside a valid directive without taking the matter to the Mental Health Review Board is acting outside the Act. In day-to-day practice the directive is still newly established and under-used, so the working knowledge that actually protects a patient is simple - a valid, known directive is binding, and it is displaced only in the specific ways the Act allows.

5.2 When the directive operates: the capacity trigger

A directive is not a standing instruction that runs from the day it is signed. It is dormant while the person has capacity and comes alive only at a defined moment. It is invoked only when the person ceases to have the **capacity** to make mental-healthcare and treatment decisions, and it remains in effect until that capacity is regained. The statutory test of that capacity is not restated here - it is taught where this chapter defines mental illness and the capacity to make treatment decisions - but its structural role in this topic is decisive: capacity is the switch. While it is present, the directive is silent; when it is lost, the directive speaks; when it returns, the directive falls silent again.

Holding this clearly is what prevents the errors that follow. If the directive operates only during incapacity, then it cannot bind a person who still has capacity - which is the subject of the self-override rule - and it cannot be a permanent surrender of autonomy, because the person recovers the decision the moment capacity returns. The directive is therefore best understood as a bridge across a period of incapacity, built by the person while they have capacity and dismantled automatically when capacity is regained.

5.3 The self-override rule

The most examined point in the whole topic is that the maker can defeat their own directive simply by having capacity. Any decision made by a person while they have the capacity to make mental-healthcare and treatment decisions shall over-ride any previously written directive by that person. The verb is mandatory: the contemporaneous capacitous decision does not merely compete with the earlier directive, it prevails over it. This is not a loophole; it is the Act being consistent with itself. Autonomy is respected in the present tense, so the wishes a person actually holds while competent must beat the wishes they recorded earlier for a time when they expected not to be competent.

It is worth seeing why the Act declines to treat a directive as an unbreakable pre-commitment against the recovered self. A person may reasonably want to bind their own future - to guard against a relapse in which their judgement is impaired - and the Act honours that wish precisely by giving the directive force during periods of incapacity. What it will not do is let a past self overrule a present competent one. The instant capacity is present, the law treats the person as the best author of their own care, and the earlier document steps aside without ceremony or paperwork. The directive protects the person from their incapacitated future, not from their capacitated present.

TRAP **An advance directive does not bind a person who still has capacity.** Candidates assume a written directive governs from the moment it is signed, and clinicians occasionally invoke it to hold a patient to an earlier refusal. In law the directive operates only once capacity is lost, and even then a decision the person makes while capacitous over-rides it. Applying a directive against the present, capacitous wishes of the patient inverts the very provision it claims to rely on.

5.4 Revocation, amendment and cancellation

Separate from over-riding a directive by a present decision is the maker's formal power to unmake it. **Revocation**, amendment or cancellation of a directive sits at section **8**. A directive may be revoked, amended or cancelled by the person who made it, at any time. The precision that earns the mark lies in the actor and the procedure. The power belongs to the maker alone - not to a relative, not to the treating team, not to the establishment - and it is exercised at any time, which in practice means while the person has the capacity to take such a step. And the procedure for revoking, amending or cancelling shall be the same as the procedure for making a directive: the same formality that created the document is required to change or undo it, so a directive cannot be quietly set aside by an informal note.

It is worth fixing the difference from the previous rule. The self-override is automatic and situational - a capacitous decision simply prevails, with no paperwork - whereas revocation is a deliberate, formal act that alters or ends the document itself. Both are the person's own, and neither needs the Board; that is what separates them from the override route that does.

5.5 The override machinery and the Mental Health Review Board

This is the required core of the topic. Following a valid directive is a duty, not a preference: it is the duty of the medical officer in charge of the mental health establishment and of the treating

psychiatrist to follow a valid directive, and that duty gives way only to the review power described here. The override itself is set at section **11**. Where a mental health professional, or a relative, or a **care-giver** of the person desires not to follow a directive, that person shall make an application to the concerned **Mental Health Review Board** to review, alter, modify or cancel it. The modal verb is doing heavy work: the objector is not permitted to disregard the directive unilaterally; they shall apply. Unilateral departure from a valid directive is not an option the Act leaves open.

On receiving the application, the Board shall, after giving an opportunity of hearing to all concerned parties - expressly including the person whose directive is in question - either uphold, modify, alter or cancel the directive. In deciding, the Board takes into consideration -

- whether the directive was made of the person's free will and free of coercion;
- whether it was intended to apply to the circumstances that have actually arisen;
- whether the person had sufficient information when the directive was made;
- whether the person had the capacity to make the decision at the time the directive was made;
- whether the contents of the directive are contrary to law or to the Constitution.

Read together, the matters the Board weighs form a coherent test of whether the directive genuinely represents the person's authentic, informed and applicable choice. Free will and the absence of coercion go to whether the document is truly the person's own at all. Whether it was meant for the situation that has actually arisen guards against a general instruction being stretched to a case its maker never contemplated. Sufficiency of information asks whether the choice was a considered one rather than an uninformed reflex. Capacity at the time of making tests whether the maker could validly bind their future self in the first place. And the check for legality ensures the Act is not turned into a device to compel what no clinician could lawfully do. The override is therefore not a veto on directives a treating team finds inconvenient; it is a structured examination of whether a directive is authentic, informed, applicable and lawful before it is set aside, and the effort of persuading the Board falls on the party who wishes not to comply, not on the person who made the directive.

The composition and wider functions of the Board belong to this chapter's account of the Mental Health Review Boards; what matters here is its unique position - it is the exclusive first-instance forum that can set aside a valid directive against the maker's wishes, doing so only on application and only after a hearing. Its decision is itself appealable to the relevant High Court under section eighty-three, on application by any person or establishment aggrieved by it, within a prescribed window from the decision.

RULE **A valid advance directive must be followed - subject to the Board's power of review and to the statutory non-application to emergency treatment.** The duty to comply falls on the medical officer in charge and the treating psychiatrist, and outside emergency treatment it yields not to the clinician's own disagreement but only to a Board that has been asked, on application, to uphold, modify, alter or cancel the directive after hearing the parties.

Separate from the Board's review power is a statutory non-application rule. Section nine provides that an advance directive does not apply to emergency treatment. The enacted text describes that carve-out as emergency treatment under section one hundred and three, but the Act's own emergency-treatment provision is section ninety-four, and section one hundred and three in fact concerns prisoners - an internal cross-reference defect in the statute's own text, not a drafting choice for a reader to silently repair. During emergency treatment, therefore, the directive simply does not govern the situation; nothing is displaced by application or hearing, because the directive was never engaged for that treatment in the first place.

5.6 The clinician's liability, and the section that is not the override

The Act protects the clinician on both sides of the decision, and it does so at a section that is frequently misremembered. Liability in relation to a directive is set at section **13**. A medical practitioner or mental health professional shall not be held liable for any unforeseen consequences of following a valid directive; and shall not be held liable for not following a valid directive if he has not been given a copy of it. The symmetry is deliberate: the clinician who does the lawful thing, honouring a directive, is shielded from its unforeseen fallout, and the clinician who fails to honour one is excused only where the directive was never placed in their hands. Ignorance protects only genuine ignorance.

The provision is doing quiet policy work behind that symmetry. By shielding the clinician who follows a directive from its unforeseen consequences, it removes the defensive incentive to second-guess or quietly ignore a patient's recorded wishes. By withdrawing that shield the moment a copy has been supplied, it makes receipt of the directive the event that fixes the duty to act on it. The safe posture for the clinician is therefore an active one rather than a passive hope of never having seen the document: ask whether a directive exists, obtain a copy, and follow it unless and until the Board directs otherwise. A directive that sits unread in a family's possession protects no one, and the clinician who takes trouble to find it is the clinician the section rewards.

PITFALL

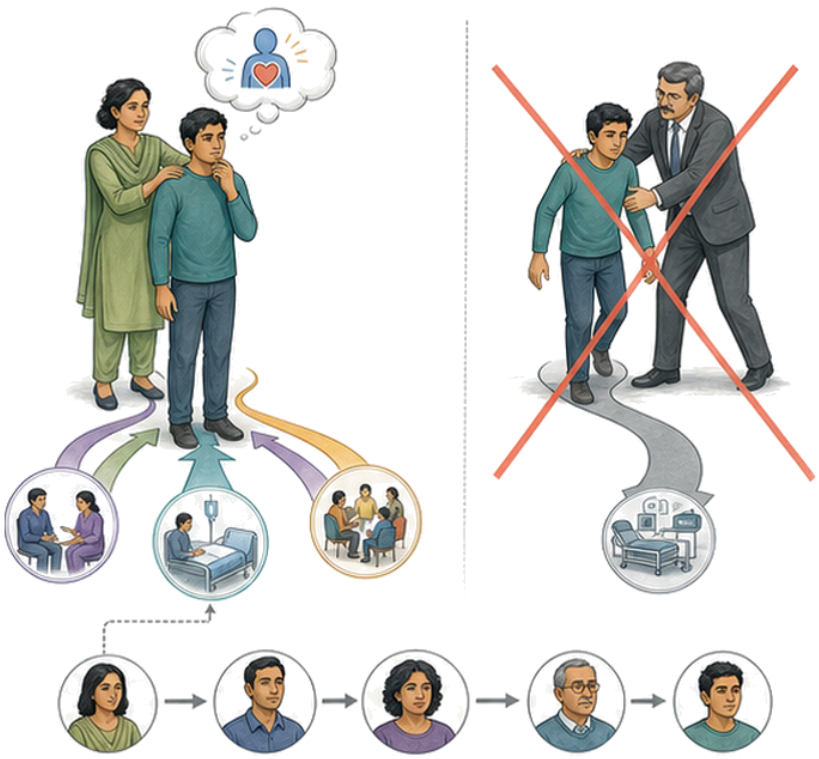
A surprisingly common error, repeated even in some question papers, is to name the liability provision as the source of the override power. They are different sections doing different work. The power to review, alter, modify or cancel a directive is the Board's, exercised only on application; the liability provision does something else entirely - it shields the clinician who follows a valid directive and the clinician who was never given a copy. Treating the liability section as the route to override, or telling a family that it lets them set a directive aside, misstates the law.

GOOD TO REMEMBER

At admission, ask whether the patient has made an advance directive and obtain a copy for the record. The liability provision excuses a failure to follow a directive only where no copy was given, so an unlocated directive is at once a clinical and a medico-legal gap: a directive can be honoured only once it is known, and the clinician's protection for not following one runs out the moment a copy reaches them.

5.7 The routes distinguished

The whole topic resolves into a single discrimination: who can change or displace a valid directive, and by what route. Setting the possibilities side by side shows why the section, the actor and the verb must be learned together rather than as a gist.



ROUTE	WHO ACTS	WHAT HAPPENS	BOARD NEEDED?
Contemporaneous capacitous decision	the person, while they still have capacity	their present decision over-rides the earlier directive	No
Revocation, amendment or cancellation	the person who made it, at any time	the directive is revoked, amended or cancelled, by the same procedure as making it	No
Review on application	a mental health professional, relative or care-giver who does not wish to follow it	the Board shall, after a hearing, uphold, modify, alter or cancel it	Yes - the only third-party route

Read down the last column and the architecture is clear. The person retains control by two means that need no one's permission - by deciding while capacitous, and by revoking formally. A dissenting third party has a single lawful path, and it runs through the Board, on application, after a hearing. There is no self-help override for a relative or a clinician who simply disagrees. This table covers only the three routes that change or displace a directive; it does not include section nine's separate rule that a directive has no application to emergency treatment at all.

> A valid advance directive governs care only while the person lacks capacity, and not at all during emergency treatment; their own capacitous decision over-rides it, the maker alone may revoke it, and the Mental Health Review Board, on application by a clinician, relative or care-giver, is the exclusive first-instance forum that may override it against the maker's wishes, subject to appeal to the High Court.

6 · Nominated representative (appointment, duties)

Why this earns marks. The **nominated representative** is the Mental Healthcare Act's answer to a hard practical question: when a person with mental illness cannot, for a period, make or communicate their own decisions about care and treatment, who stands beside them and, where necessary, acts on the record - and by what standard must that person reason? The topic is a compact cluster of provisions covering appointment, the default order where no appointment has been made, and the representative's duties, and it threads through almost every other mechanism of the Act: the advance directive names a nominated representative, supported admission is applied for by one, and the person's healthcare rights are exercised with one's support. A candidate who keeps appointment, default and duties apart, and who reads each modal verb exactly, has shown they can work with a statute rather than paraphrase its gist.

- Appointment
- Default order
- Support the person
- Give weight to wishes
- Not a substitute guardian

Fig 25.4 Under the Mental Healthcare Act, the nominated representative supports decision-making and gives weight to the person's own wishes. Appointment, the default order and statutory duties must be kept distinct; the role is not an unrestricted substitute guardianship.

The recurring difficulty is that the office is easily misread as a guardian or a next-of-kin who consents on the patient's behalf. The Act builds something narrower and more demanding. The representative is a supporter, not a substitute: their statutory task is to help the person decide and to give weight to the person's own wishes, not to decide in the person's place. Everything that earns a mark in this topic follows from that single distinction, so it is worth fixing before the mechanics: the appointment provision creates the office and supplies a fallback where none is chosen; the duties provision fixes the standard by which the holder must act.

14	5	17
APPOINTMENT	DEFAULT TIERS	DUTIES

6.1 The right to appoint a nominated representative

The right to appoint sits at section **14**. Every person who is not a minor shall have a right to appoint a nominated representative. The verb is doing real work: this is a right conferred in mandatory terms on the individual, not a facility that the establishment or the family may extend or withhold at its discretion. The appointment is deliberately low in formality so that the right is genuinely usable, but the Act is specific about what a valid one requires:

- it is made in writing, on plain paper, authenticated by the person's signature or thumb impression, and it needs neither a lawyer nor a registrar to be valid;
- the person appointed must be an adult and not themselves a minor;
- the appointee must be competent to discharge the role;
- the appointee must consent, in writing, to act.

Consent matters because the office carries duties, and a person cannot be conscripted into speaking for another without agreeing to do so. Each element is modest on its own, but together they mark the appointment out as a real legal act with a willing, capable holder, rather than a name casually written on a form.

Two points are commonly examined here as one-liners. First, the right belongs to the person and is exercised while they can exercise it: a competent adult sets down, in advance or at the time, whom they trust to support them. Second, the appointment can be undone and remade as the person's circumstances and relationships change, because the right that creates the office is a continuing one and not a single irreversible act. Holding this clearly prevents the error of treating a once-named representative as fixed for life.

IN INDIA

The signature-or-thumb-impression formality is a characteristically Indian piece of drafting: it makes the right real for a population with wide variation in literacy, so that a person who cannot sign is not thereby denied a voice in who supports them. In day-to-day practice the office is still newly established and under-used, and many families arrive at admission with no idea that the appointment is the patient's to make. The working knowledge that actually protects a patient is therefore simple - the choice of representative is the person's own, made informally but in writing, and it is not the hospital's to assign.

6.2 The default order of precedence where none is appointed

Most people never appoint anyone in advance, so the Act cannot let the office stand empty at the moment it is needed. Within the same appointment provision it supplies a default: where no representative has been appointed, the following persons shall be deemed to be the nominated representative, in a fixed **order of precedence**. The deeming verb is mandatory - the law does not merely permit one of these people to step in, it treats them as the representative in turn until an available and willing person is found.

ORDER	WHO IS DEEMED THE NOMINATED REPRESENTATIVE	HOW THEY COME TO THE ROLE
First	The individual the person named in their advance directive	The person's own prior choice, carried across from the directive
Then	A relative	Deemed only if available and willing to act
Then	A care-giver	Deemed only if no relative is available or willing
Then	A suitable person appointed by the concerned Board	Appointed where no relative or care-giver can act
Last	The Director, Department of Social Welfare, or a designated representative	The Board shall appoint this office where no other person is available

Read the column of conditions and the design becomes clear. The order runs from the most personal choice to the most institutional backstop, and it never leaves a person unrepresented: if family and community fail, the concerned Board picks a suitable person, and if even that fails, the Board shall appoint the **Director, Department of Social Welfare**, so that a representative always exists. There is a further safeguard for the gap before the Board can act: a person representing an organisation registered under the Societies Registration Act, 1860, or under any other law, and working for persons with mental illness, may be engaged as the representative pending the Board's appointment. That initial engagement is discretionary. But once the representing person makes a written application to act, the medical officer in charge of the establishment or the psychiatrist in charge of the person's treatment shall accept the application, so the person becomes the temporary representative as a matter of duty, not choice, until the proper appointment is made.

The single most useful thing to carry from the order is that it is a default, displaced entirely by an appointment. An appointed representative, even one who is not a relative, outranks the whole deeming list; a **care-giver** or relative is deemed to hold the office only in the absence of a valid appointment and only in their place in the queue. This is why appointment and default must be learned as two limbs of one provision rather than as a single rule about who speaks for the patient.

PITFALL

A common clinical error is to treat the nearest relative as automatically and always the representative, and to seek that relative's consent as though the office were a matter of kinship. It is not. Where the person has appointed someone, that appointee holds the office whatever the family's wishes; and even under the default, a relative ranks below the person's own advance-directive choice and is deemed to act only if available and willing. Reaching for the nearest relative by reflex can put the wrong person in the role and sideline the patient's own prior choice.

6.3 Appointment implies nothing about capacity

One provision within the same section removes a misunderstanding that would otherwise undo the whole reform. The Act is explicit that appointing, or failing to appoint, a nominated representative does not imply that the person lacks the capacity to make mental-healthcare and treatment decisions. The two questions are kept entirely separate. Naming a representative is a piece of forward planning that a fully capacitous person does precisely because they are thinking ahead; it is not a confession of present incapacity, and it does not lower the person's standing to decide for themselves here and now.

This matters because the older model it replaces ran the other way: to have someone speak for you was to be, in the law's eyes, someone who could not speak. The Mental Healthcare Act breaks that link on purpose. A person may have a representative in place and still make their own valid decisions across most of their care; the representative comes forward only for the decisions the person cannot presently make. The capacity that triggers that hand-over is the treatment-decision capacity defined where this chapter sets out the definition of mental illness and the capacity to make treatment decisions, and it is not restated here; what belongs to this topic is only the negative rule - representation and incapacity are not the same fact, and neither is evidence of the other.

6.4 The duties of the nominated representative

This is the required core of the topic. The standard by which the representative must act is set at section **17**, and its verbs are mandatory throughout. While fulfilling the role, the representative shall consider the person's current and past wishes, their life history, their values, their cultural background, and their **best interests**. The list repays attention because it refuses to collapse into a bare best-interests test. Wishes, history, values and cultural background are placed alongside best interests, not beneath them, so the representative cannot substitute a tidy external judgment of what is good for the person for the harder work of reconstructing what this particular person would want.

The second duty sharpens the first. The representative shall give **particular credence** to the views of the person, to the extent that the person understands the nature of the decisions under consideration. This is a sliding, decision-specific weighting rather than an all-or-nothing switch: the more the person grasps of a given decision, the more their own view must govern it, even during a period when they cannot make the decision unaided. The third duty states the purpose the first two serve - the representative shall provide support to the person in making treatment decisions. The office exists to enable the person's own decision-making wherever it can reach, and to speak in the person's voice, reconstructed from the first duty's materials, only where it cannot.

RULE **The representative's duty is to support the person's own decision-making, not to replace it.** The statute is framed in mandatory terms: the holder shall consider the person's present and past wishes, life history, values and cultural background; shall give particular credence to the person's own views in proportion to how well they understand the decision; and shall provide support in making treatment decisions. Best interests sits within that reconstruction of the person's will, not above it.

Beyond these core duties, the representative is the person the Act turns to at several other points in the patient's journey. The representative may apply for the person's admission and take part in decisions about discharge and discharge planning, may seek information about the diagnosis and the proposed treatment so that support is informed rather than nominal, and gives or withholds consent to research on the person's behalf within the limits the Act sets. The consent role also reaches the regulated treatments, including electroconvulsive therapy, whose consent machinery this chapter treats in its own right and which is not reopened here. The section anchors for these wider functions lie in provisions this topic does not own, so they are named as functions rather than pinned to numbers, but the shape is worth carrying: the representative is not a one-decision proxy but a continuing supporter across admission, treatment, information and discharge.

6.5 Supported decision-making, not substitute/best-interests decision-making

The conceptual heart of the office, and the point most often lost, is the model of decision-making the duties encode. The older tradition of guardianship worked by **substitute/best-interests decision-making**: a guardian decided in the person's place, asking what a reasonable person, or the guardian, would choose. The Mental Healthcare Act adopts **supported decision-making** instead. The representative's job is to furnish the support - information, presence, help in weighing options, and a faithful account of the person's own wishes and values - that lets the person decide as far as they are able, and to carry the person's reconstructed will only for the residue they cannot reach.

AXIS	SUPPORTED DECISION-MAKING (THE REPRESENTATIVE'S STANDARD)	SUBSTITUTE/BEST-INTERESTS DECISION-MAKING (THE OLDER MODEL)
Who decides	The person, supported; the representative fills only the gap the person cannot cross	The proxy, in the person's place
Weight of the person's own view	Given particular credence, in proportion to how far the person understands the decision	Often displaced once a proxy is appointed
Reference point	The person's wishes, history, values and cultural background, and their best interests together	A best-interests or reasonable-person judgment made for the person
Effect of having a representative	No implication that the person lacks capacity to decide	Appointment historically signalled incapacity

The contrast is not academic. It changes what the representative should actually do at the bedside: not announce a decision, but sit with the person, explain the options in terms the person can follow, and decide unaided only what genuinely cannot be reached with support. It also explains why the duties are drafted as they are - the emphasis on wishes, values and particular credence is the machinery that keeps support as the default, so that the representative consents on the person's behalf only where the person needs nearly total support to decide, and even then only as a temporary measure kept under frequent review of the person's capacity.

TRAP **Describing the nominated representative as a substitute decision-maker who consents on the patient's behalf.** Candidates equate the office with a guardian or next-of-kin proxy, and clinicians sometimes obtain the representative's consent as if the patient had dropped out of the picture. The statutory duties point the other way: the holder must give particular credence to the person's own views and provide support in the person's own decision-making. Treating the representative as a routine proxy inverts the standard the section actually imposes.

6.6 Reading the office correctly in practice

Pulling the provisions together, the office resolves into three questions a clinician can ask in order. Is there an appointed representative? If so, that person holds the office, whatever the family's preferences, provided the appointment was validly made and the appointee competent and consenting. If not, who is deemed to hold it under the default order, worked down from the advance-directive choice through relative and care-giver to the Board's appointee and, in the last resort, the Director, Department of Social Welfare? And once the holder is identified, are they discharging the duties the Act imposes - supporting the person's own decisions and giving particular credence to the person's views - rather than deciding in the person's stead? Each question maps onto a limb of the topic, and answering them in that sequence is how the statute is meant to be used.

The office also has to be kept in its lane. It is a healthcare-facing role: it supports the person's decisions within the mental-healthcare system and reaches neither the person's property nor their money, which are the concern of the separate guardianship and property-management machinery this chapter treats elsewhere. Conflating the two offices, so that a representative is asked to sign for an estate or a property manager to consent to treatment, is a standing source of error and a genuine safeguarding risk.

GOOD TO REMEMBER

At every admission and at each major treatment decision, establish who the nominated representative is before you seek anyone's involvement: ask whether the person has appointed one, and if not, walk the default order rather than defaulting to whichever relative is present. Record the answer. Then treat that person as a supporter of the patient's own decision-making, not as a consent-giver who displaces the patient - which is exactly what the duties require, and exactly what a hurried ward routine tends to forget.

Every non-minor has a mandatory right to appoint a nominated representative in writing; where none is appointed the Act deems one in a fixed order, from the advance-directive choice down to the Director, Department of Social Welfare; and the holder's duty is to support the person's own decisions and give particular credence to their views, not to decide in their place.

7 · Admission types (independent, supported admission and discharge procedures)

Why the marks cluster here. Admission is where the Mental Healthcare Act 2017 stops declaring principles and starts issuing procedure, and examiners return to it because it is the

point at which the Act's central idea becomes a set of hard rules a clinician can get wrong. That idea is that the route a person takes into inpatient care follows their capacity to make treatment decisions, not their diagnosis and not the convenience of the service. The Act therefore builds a graded ladder rather than a single admission order: an independent route the person asks for himself, a supported route that another person applies for on his behalf, and an emergency provision that holds a dangerous situation before either can be arranged. Each rung carries its own examiners, its own clock, its own reporting duty and its own modal verb, and the questions that separate a pass from a distinction live in the differences between them.

This section teaches those routes and the discharge procedures that close them. The capacity test itself, what it means to be able to understand, appreciate or communicate a treatment decision, is defined elsewhere in this chapter and is only invoked here. The point to hold is that capacity is the switch, and every provision below is a setting of that switch.

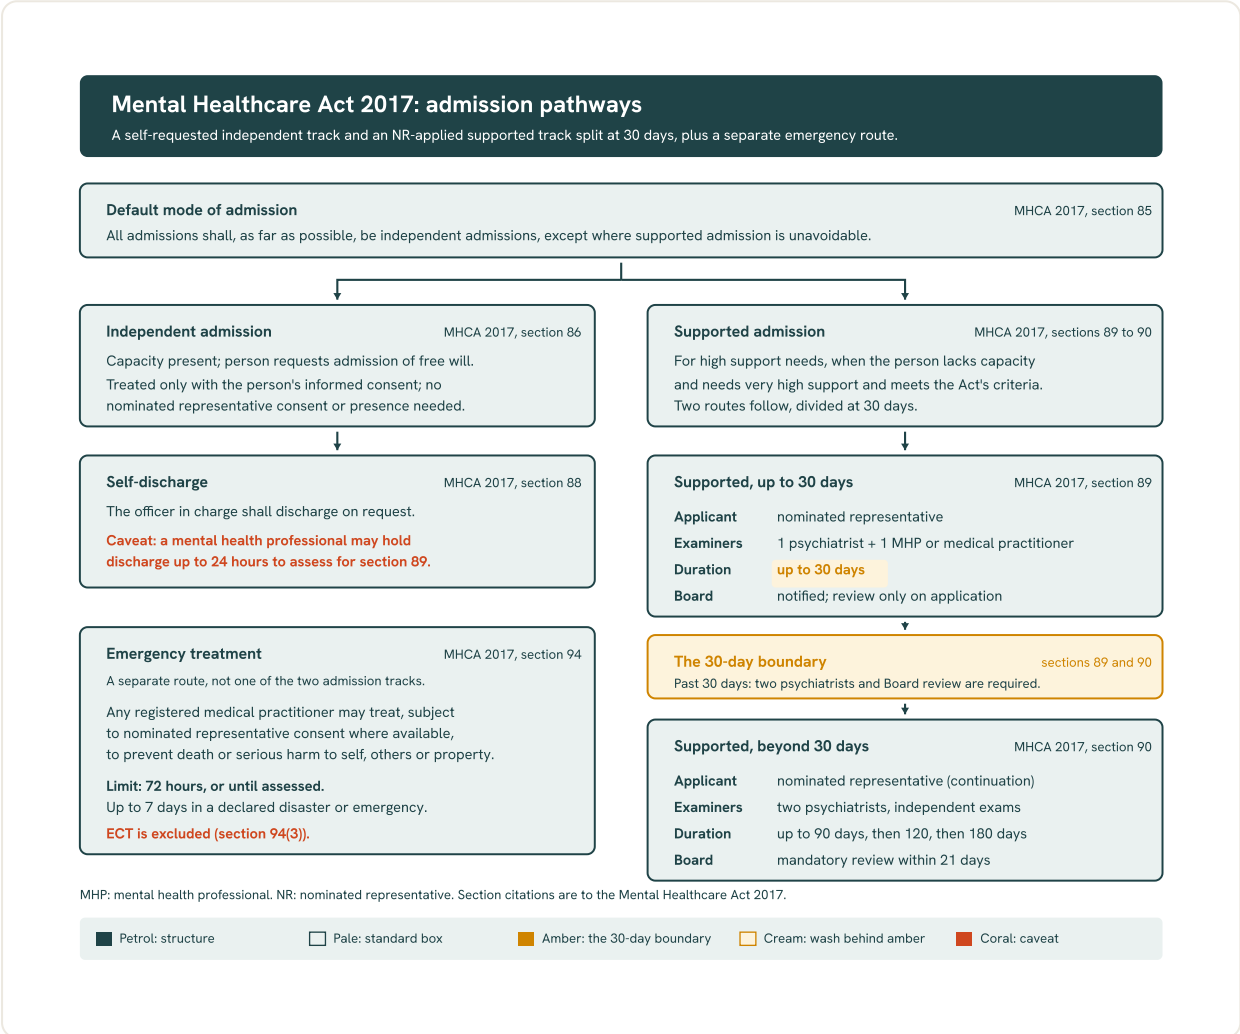


Fig 25.5. Admission under the Mental Healthcare Act 2017 runs on two tracks that differ in who initiates them: a self-requested independent admission (section 86, capacity present, on the person's own request and informed consent, with no nominated representative needed) and a supported admission for high support needs, applied for by the nominated representative, which the 30-day boundary divides into section 89 (one psychiatrist with one other professional; up to 30 days) and section 90 (two psychiatrists examine independently; mandatory Board review within 21 days). Emergency treatment (section 94) is a separate 72-hour route that excludes electro-convulsive therapy.

7.1 The default the Act commands (section 85)

The Act opens its admission scheme by defining the **independent patient** and, in the same breath, by making that status the default. An independent admission is the admission of a person who has the capacity to make his own mental-healthcare and treatment decisions, or who needs only minimal support to make them. The definitional provision does more than label a category. Its second limb lays down a rule of priority: all admissions to a mental health establishment *shall*, as far as possible, be independent admissions, and a supported admission is lawful only where conditions exist that make it unavoidable.

Read that modal verb precisely, because the examiner will. The Act does not say a clinician *may* prefer the independent route; it says every admission *shall* be independent so far as possible. Supported admission is the exception that has to be justified, not a parallel option of equal standing, and it is why the choice of admitting section is never a matter of clinical taste.

RULE **The mode of admission follows capacity, and independent admission is the default the Act mandates.** A supported admission is not an alternative a clinician may reach for out of convenience; it is the exception the statute permits only when the person's decision-making capacity, or a defined risk, makes the independent route unworkable. Every question about which section applies begins by asking what the person can decide, not what he is diagnosed with.

IN INDIA

The 2017 Act rebuilt admission around this default deliberately. For the practising psychiatrist the burden has shifted: the record must show why an independent admission was not possible before a supported admission is used, and a supported admission that could have been an independent one is a departure from what the Act commands, not a neutral choice.

7.2 Independent admission and treatment (section 86)

The operative provision for the independent route is the one under which a person who is not a minor, who considers himself to have a mental illness and who wishes to be treated, *may request* the medical officer or mental health professional in charge to admit him. The request is the patient's own, and the initiative sits with him. On receiving it the officer *shall* admit the person where satisfied that the illness is severe enough to need admission, that the person is likely to benefit from it, that he understands the nature and purpose of the admission and is asking of his own free will, and that he has the capacity to make the decision or needs only minimal support. The duty is expressed as a "shall", but it is a conditional duty: the officer admits if and only if those conditions are met, and refuses if they are not.

Two consequences of independent status are examined repeatedly. First, an independent patient *shall not* be given any treatment without his own **informed consent**. Admission does not import a power to treat, and a capacitous inpatient who refuses a specific intervention keeps that refusal. Second, the establishment *shall not* require the consent or the presence of a nominated representative, a relative or a care-giver in order to admit an independent patient. The person

stands on his own capacity, and inserting a family gatekeeper into an independent admission is not something the Act permits.

7.3 Self-discharge and the twenty-four-hour hold (section 88)

Because the independent patient is admitted on his own capacity, he keeps the key to the door. He *may* discharge himself without the agreement of the officer in charge, a right of **self-discharge** that follows directly from independent status, and on his request the officer *shall* discharge him immediately. This is the ordinary rule: a person admitted on his own decision may reverse that decision.

The provision then supplies the exception that examiners love, because it is a narrow, conditional power that candidates routinely overstate. Notwithstanding the right to self-discharge, a mental health professional *may* prevent the discharge of an independent patient for up to **twenty-four hours**, and for one purpose only: to allow the assessment needed to decide whether a supported admission is warranted. The power arises only where the professional is of the opinion that the person:

- is unable to understand the nature and purpose of his decisions and requires substantial or very high support from his nominated representative;
- has recently threatened or attempted, or is threatening or attempting, to cause bodily harm to himself;
- has recently behaved or is behaving violently towards another person, or has caused or is causing another person to fear bodily harm from him; or
- has recently shown or is showing an inability to care for himself to a degree that places him at risk of harm to himself.

At the end of that window the person *shall* either be admitted as a supported patient under the next provision or be discharged, within that window or on completion of the assessment, whichever is earlier. The hold is a bridge to a decision, not a decision in itself.

> **GOOD TO REMEMBER**
>
> The twenty-four-hour hold is an assessment window, not an authority to treat. It buys time to decide whether a supported admission is justified; it does not, by itself, let you medicate a refusing patient. If treatment genuinely cannot wait for that decision, the question is whether the separate emergency provision applies, not whether the hold has quietly turned into a treatment order.

7.4 Supported admission up to thirty days (section 89)

When the independent route is genuinely unworkable, the Act turns to **supported admission**, the mechanism for a person with **high support needs** who cannot presently make or communicate the admission decision himself. The first supported-admission provision governs shorter admissions, and it is initiated not by the patient but by an application from his nominated representative. The officer *shall* admit the person on that application only once a defined examination has been done: the person must have been independently examined, on the

day of admission or within the preceding **seven days**, by **one** psychiatrist together with a second examiner who is a mental health professional or a medical practitioner. Their task is not merely to confirm illness but to certify that a supported admission is the **least restrictive** option that meets the person's needs. The distinct admission procedure that applies to minors is a separate provision and is not set out here.

The admission this provision authorises *shall* be limited to **thirty days**. That ceiling is the defining feature of the shorter route and the hinge on which the whole supported-admission scheme turns. A reporting duty attaches to it: the officer *shall* report the admission to the concerned Board within **three days** where the patient is a woman or a minor, and within **seven days** for any other person. Note what that reporting is and is not. It informs the Board; it is not a requirement that the Board clear the admission before it takes effect. Under this shorter route the Board's review is not an automatic pre-authorisation, it is triggered when the patient, his nominated representative or a recognised organisation applies for it. That is the crucial contrast with the longer route below.

Finally, the provision carries its own escalation valve. If the officer forms the opinion that the person is likely to need treatment beyond that ceiling, he is duty-bound to *refer* the matter to be examined by **two** psychiatrists for admission beyond that period. The shorter route cannot simply roll over; crossing the ceiling demands a fresh and higher threshold of scrutiny, which is the subject of the next provision.

7.5 Supported admission beyond thirty days (section 90)

The second supported-admission provision is a genuinely different instrument, not a mere continuation, and collapsing the two is one of the commonest ways to lose the mark. It applies when a person already admitted under the shorter route needs continuous admission beyond that ceiling, or is being readmitted soon after a discharge. Several things change, and each of them tightens the test.

First, the examination is heavier. The person must have been independently examined in the preceding **seven days** by **two** psychiatrists, each of whom must independently reach the required conclusion. Second, the risk threshold is worded more stringently: where the shorter route spoke of a person who had *recently* threatened or attempted harm, this provision requires that the person has done so *consistently over time*. A single recent episode that would support the shorter admission does not, on its own, support the longer one.

Why the Board matters here. The third change is the one the examination cares about most: the Board's role turns from reactive to mandatory. The officer *shall* report every admission and readmission under this provision to the concerned Board within **seven days**. The Board then *shall*, within **twenty-one days** of the last admission or readmission, either permit the admission or order the person's discharge. This is not an optional review that someone has to ask for; it is a compulsory adjudication the Board must complete, and it is the real safeguard that separates long-term supported admission from short.

The durations are correspondingly longer and tiered. An admission under this provision *shall* be limited to **ninety days** in the first instance. Beyond that it *may* be extended by a further **one hundred and twenty days** at the first extension, and thereafter by **one hundred and eighty days** on each subsequent occasion. The lengthening intervals are matched to the mandatory Board oversight, so that a longer detention always sits under a heavier external check rather than a lighter one.

TRAP **Board review is automatic only for the longer supported admission, not for the shorter one.** Candidates write that "the Board must approve supported admission", flattening the two provisions into one. Under the shorter route the admission takes effect on the examiners' certificate and the Board is merely notified, reviewing only if someone applies; under the longer route the Board must, within its fixed period, positively permit the admission or order discharge. Always say which route you mean and match the Board's role to it.

7.6 The routes compared

Set against one another, the routes separate cleanly on who initiates them, who examines, how long they last and what the Board does. The accompanying table lays out the axes the examiner tests. Commit the pattern rather than the isolated numbers, because a viva question almost always asks you to move a patient from one column to the next.

AXIS	INDEPENDENT (SECTION 86)	SUPPORTED, UP TO THIRTY DAYS (SECTION 89)	SUPPORTED, BEYOND THIRTY DAYS (SECTION 90)
Who initiates	The patient's own request	Application by the nominated representative	Application by the nominated representative, for continuance beyond **thirty days** or qualifying readmission within **seven days** of discharge
Capacity assumed	Has capacity or needs minimal support	High support needs	High support needs, persisting
Examiners	Satisfaction of the officer in charge	One psychiatrist plus a second examiner	Two psychiatrists, independently
Harm threshold	Not applicable	Recently or currently: self-harm threat or attempt, violence or causing another to fear bodily harm, or inability to self-care at a degree of risk	The same three limbs, but shown consistently over time rather than recently or currently
Duration	Not time-limited by this provision	Capped at **thirty days**	**ninety days** first, then extensions
Board's role	None for admission	Notified, reviews on application	Must permit or order discharge within **twenty-one days**
Exit	Self-discharge on request	On expiry or clinical decision	Board may order discharge

7.7 Emergency treatment before admission (section 94)

Between the moment a crisis presents and the moment a formal admission can be arranged sits **emergency treatment**, and the Act keeps it deliberately separate from the admission provisions. Any registered medical practitioner, not only a psychiatrist, and whether at a health establishment or in the community, *may* provide any medical treatment, including treatment for mental illness, subject to the informed consent of the nominated representative where one is available. The power exists only where treatment is immediately necessary to prevent death or irreversible harm to the person's health, or the person inflicting serious harm on himself or others, or the person causing serious damage to property as a consequence of his mental illness. Emergency treatment in this sense expressly includes transporting the person to the nearest establishment so that a proper assessment can be made.

Two limits define the provision and are examined precisely. First, it is time-bound: emergency treatment is limited to **seventy-two hours**, or until the person has been assessed at a mental health establishment, whichever is earlier; only where the appropriate Government has declared a disaster or emergency may that period extend up to **seven days**. Second, and this is the line candidates miss, nothing in this provision permits the use of electro-convulsive therapy as a form

of treatment. Emergency powers are wide as to who may act and what ordinary treatment may be given, but they stop firmly short of ECT. The clinical technique and consent for ECT itself belong to the ECT and neurostimulation notes and are not taught here; what the admission law fixes is that the emergency route is not a back door to it.

PITFALL

A floridly catatonic or acutely suicidal patient can look like exactly the case for urgent ECT, and a clinician who reaches for it under emergency powers has misread the statute. The emergency provision authorises ordinary treatment to hold a dangerous situation; it excludes ECT outright. Urgent ECT must be routed through its own consent and authorisation machinery, never through the emergency window.

7.8 Discharge, escalation and the shape to memorise

Discharge mirrors admission. The independent patient, admitted on his own decision, is discharged on his own request, subject only to the narrow twenty-four-hour hold examined above. The supported patient's exit is governed instead by time and by oversight: the shorter admission ends when its ceiling is reached unless it has been lawfully escalated, and the longer admission sits under a Board that may order discharge at its mandatory review. Escalation and discharge are therefore opposite directions of the same supervised process, and the examiner's scenarios usually turn on moving a patient correctly from one rung to the next rather than on any single figure.

86	89	90	94
INDEPENDENT ADMISSION	SUPPORTED, SHORTER ROUTE	SUPPORTED, LONGER ROUTE	EMERGENCY TREATMENT

MNEMONIC

Ask, Apply, Escalate, and Bridge

The independent patient **asks** for himself; the shorter supported admission is one the nominated representative **applies** for; the longer supported admission is an **escalation** demanding a second examining psychiatrist and a mandatory Board decision; and emergency treatment is the **bridge** that holds a crisis until one of those routes is settled. The verbs map to the provisions in the order a real case moves through them.

Independent admission is the default the Act commands; supported admission is the justified exception, and it splits into a shorter provision and a longer, Board-supervised one, never collapsing into a single rule.

8 · Mental Health Review Boards (composition, functions)

A charter of rights is only as strong as the forum that enforces it. The Mental Healthcare Act is written, to an unusual degree for an Indian health statute, as a set of promises to the person with mental illness: a right to make an advance directive, a right to a nominated representative,

safeguards on how a person may be admitted and discharged, and a right to live in and be part of the community. A promise on paper is worth only as much as the body a patient can actually move when it is broken, and that body is the **Mental Health Review Board**. It is a standing, quasi-judicial forum, constituted for a district or a group of districts, that reviews involuntary care, holds and revisits advance instructions, appoints nominated representatives to support a person's own decisions and hears grievances against establishments. Examiners return to it because it is the cleanest single test of whether a candidate understands that the Act's rights are enforceable machinery and not a wish-list, and because candidates routinely confuse it with the regulatory Authority that shares the Act.

Read the Board as the hinge between the two halves of the Act. On one side sit the substantive rights and the admission architecture; on the other sits the question every rights instrument must answer, which is who decides when those rights are contested, how quickly, and with what consequence. The Board is that answer, and the Act deliberately places it close to the patient rather than in a distant court. Fix its constitution, its composition and its functions and a whole cluster of short-note and one-mark questions falls into place at once. This section teaches those three things from the primary provisions and marks the discriminations an examiner rewards.

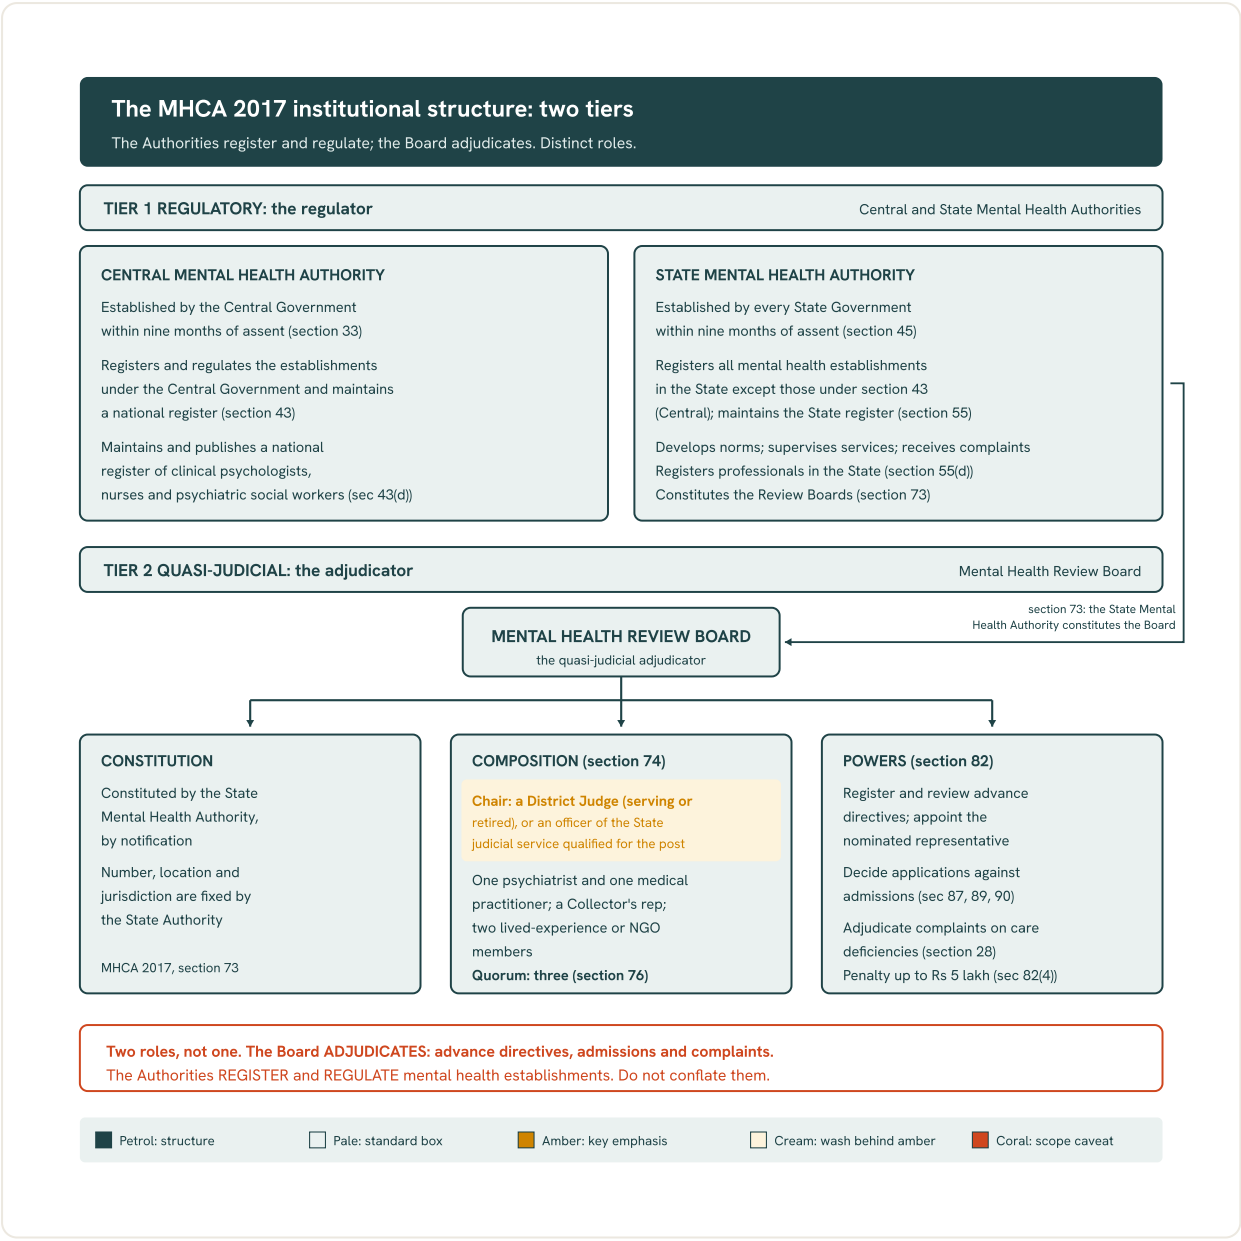

Fig 25.6. The MHCA 2017 divides its institutions into a quasi-judicial adjudicator (the Mental Health Review Board, sections 73, 74 and 82) and regulatory Authorities (Central section 33 and State section 45) that register and regulate mental health establishments; the State Authority constitutes the Board under section 73.

8.1 The rights-enforcement organ of the Act

Every rights statute faces the same design problem. A right that can be vindicated only in the higher courts is, for the person with a mental illness, a right that mostly cannot be vindicated at all, because cost, delay and distance defeat it before it begins. The Act takes the opposite decision and builds a permanent body of its own, for a district or a group of districts, to which a patient or a nominated representative can bring a grievance directly. That is why the Board is best understood not as an administrative add-on but as the enforcement organ without which the rest of the Act would be advisory.

The word that carries the most weight here is quasi-judicial. The Board does not treat patients and it does not manage services; it adjudicates. It receives applications, hears the parties, applies the provisions of the Act to the facts, and issues a reasoned order the parties are bound to obey. That places it in the family of statutory tribunals rather than clinical committees, and almost

every feature that follows, from the judicial officer in the chair to the power to impose a monetary penalty, is a consequence of that character. A candidate who fixes this one idea rarely gets the rest wrong.

RULE **The Board is a tribunal, not a clinical committee.** It is chaired by a judicial officer and it exists chiefly to decide questions of law, rights and compliance under the Act. It does not ordinarily prescribe treatment, but the Act gives it narrow, specific treatment-authorisation powers as well, including permission for ECT in a minor and approval of psychosurgery, which belong to this chapter's account of prohibited and restricted procedures and are not taught here. Its whole design - the judge in the chair, the application-and-hearing procedure, the power to bind and to penalise - follows from its adjudicating character, so sort any question by asking whether it concerns the standing of one patient's rights or the running of a service, and the answer, and the right body, follow.

8.2 Constitution of the Board (section 73)

A Board does not arise on its own, and the provision that creates it repays exact reading because it splits the responsibility across two levels of government. The duty to bring Boards into existence is mandatory and it rests on the State Mental Health Authority: it *shall*, by notification, constitute the Boards for the purposes of the Act. Read the modal verb precisely, because it is a duty and not a discretion; a State that has not notified its Boards is in default of the Act, not merely declining an available option. The requisite number of Boards, their location and their territorial jurisdiction are then specified by the State Authority in consultation with the State Government concerned, which is the mechanism that lets a populous State raise several Boards while a smaller one manages with fewer.

The third limb is the one candidates overlook. The constitution of a Board for a district, or for a group of districts, *shall* be as prescribed by the Central Government. The design is therefore split deliberately between the two levels: the Centre fixes the template and the shape of the body, uniform across the country, while the State decides how many Boards to raise and where to site them. That division buys national consistency in what a Board is and local control over how far a citizen must travel to reach one. Holding those two facts together, a central template with local reach, is what the provision is really testing.

IN INDIA

The choice to pitch the Board at the district is not incidental. A person detained against their will, or a care-giver acting for them, must be able to bring an application without crossing a State line. A body sitting only in the State capital would exist on paper and be unreachable in practice, whereas a tribunal sited within reach, in the district or group of districts it serves, turns the right to challenge a decision into a usable remedy rather than a theoretical one. The Board's authority flows down from the State Authority, but its blueprint is set centrally, and that combination of local access on a national template is a distinctively Indian federal answer to the problem of making rights reachable.

8.3 Composition: a mixed bench by design (section 74)

This is the most heavily examined provision in the group, and it is best learnt as a structure rather than a list. Each Board *shall* consist of four kinds of member, chosen so that the bench carries legal authority, administrative reach, clinical knowledge and the voice of the very people the Act exists to protect. The **chairperson** is a judicial officer, and the accompanying table sets the four seats against what each is there to bring.

SEAT	WHO HOLDS IT	WHAT IT BRINGS TO THE BENCH
Chair	A District Judge, an officer of the State judicial service qualified to be appointed a District Judge, or a retired District Judge	Judicial authority and the discipline of due process
Administrative member	A representative of the District Collector, District Magistrate or Deputy Commissioner	Administrative reach and the link to local government
Medical members	**two** members, one a **psychiatrist** and the other a **medical practitioner**	Specialist and general clinical judgement on the decisions under review
Community members	**two** members who are persons with mental illness, care-givers, or representatives of their organisations or of mental-health non-governmental organisations	Lived experience and civil-society oversight

Read the seats as functions rather than as names. The judicial chair is what makes the body quasi-judicial rather than clinical: it hears the parties, weighs the evidence and passes orders that bind, and it is led by someone trained to do exactly that. The administrative representative ties those orders to the machinery that must carry them out. The medical seats put the clinical facts of an admission or a treatment decision in front of the bench, and the deliberate pairing of a psychiatrist with a general medical practitioner, rather than two psychiatrists, guards against a purely specialist reading of a case. The community seats are the provision's most distinctive feature: by seating persons with mental illness, their care-givers and civil-society representatives on the reviewing body itself, the Act builds its participatory, rights-based ethos into the structure of the forum rather than leaving it to good intentions.

The bench does not need every seat filled to act. Its **quorum** is **three** members, so a validly constituted sitting can proceed with three present. That threshold keeps the Board workable, because a body that could meet only at full strength would stall, while still demanding a genuine plurality rather than a single decision-maker holding a person's liberty in one pair of hands.

MNEMONIC

Judge, Collector, Clinicians, Community

The four member-categories in the order the Act lists them: a **J**udge chairs the Board, the **C**ollector's office is represented, two **C**linicians sit (a psychiatrist and a medical practitioner), and two **C**ommunity members carry lived experience, the care-giver's perspective or a mental-health organisation's voice. Four Cs after the Judge, and the bench is complete.

TRAP **Do not seat a psychiatrist in the chair.** Candidates reflexively make the senior doctor the head of any mental-health body. The chair here is judicial; the psychiatrist is one of the medical members and never the chairperson. The Act deliberately separates the clinical voice from the adjudicating authority, and a script that inverts that has misread the whole design of the bench.

8.4 Powers and functions (section 82)

This is where the Act's rights become remedies. The powers and functions of the Board *shall* include all or any of the following, meaning these are its standing jurisdictions, exercised as cases arise rather than all at once. Taken together they are the mechanisms by which each protection the Act grants elsewhere becomes something the Board can test and enforce.

- to register, review, alter, modify or cancel an **advance directive**, the instrument in which a person records future treatment wishes; how it is made and when it may be overridden are dealt with where this chapter treats advance directives and are not reopened here;
- to appoint a **nominated representative** for a person who has not chosen one, the qualifications and duties of that role belonging to this chapter's account of the nominated representative;
- to receive and decide an application, brought by the person, the nominated representative or another interested person, against a decision on admission or treatment made by the medical officer or mental health professional in charge of an establishment;
- to decide applications about the non-disclosure of information to the person, where part of the record has been withheld and the withholding is contested;
- to adjudicate complaints about deficiencies in the care and services an establishment provides; and
- to visit and inspect prisons and jails.

The pattern across these functions matters more than the list. Somewhere in the Act a person is given a protection, to plan treatment in advance, to have a chosen person speak for them, to be admitted only on lawful grounds, to see their own record, to be cared for to a standard. Each of those protections is then handed a forum with the power to test it against the facts and to order a remedy. That is what converts the Act's language of rights into something a clinician and an establishment can be held to, and it is why the Board, and not the regulatory Authority, is the body a wronged patient turns to. The inspection of prisons and jails is the one function that reaches beyond the establishment; it anchors the Board's protective eye on persons with mental

illness held in custody, while the substantive psychiatry of prisoners and the report a psychiatrist prepares for a court belong to the Forensic ethics, consent and legal procedure notes and are not taught here.

PITFALL

The Board is neither the regulator nor a general grievance desk. Registering establishments and setting service standards sit with the State Mental Health Authority; criminal responsibility and fitness to stand trial sit with the courts. The Board's jurisdiction is the Act's own rights machinery - directives, representatives, admission and discharge, disclosure and standards of care - and a clinician who takes a registration question or a criminal-forensic question to the Board has picked the wrong body and lost time that a patient may not have. A rights complaint about care deficiencies is not automatically misdirected at the Authority either: it follows its own ladder, first to the establishment's medical officer or mental health professional, then to the Board, and only to the State Authority if the complainant remains dissatisfied with the Board's response.

8.5 Orders and enforcement: the Board's teeth

Because the Board adjudicates, it works by application and hearing, and an adjudicator without a sanction is only a suggestion box. The Act does not leave it there. Where a mental health establishment does not comply with the orders or directions of the Authority or the Board, or wilfully neglects them, the Authority or the Board, as the case may be, *may* impose a penalty which *may* extend up to **five lakh rupees** on the establishment. Cancellation of registration is a narrower power: only the Authority may cancel it, acting on its own or on the Board's recommendation, and only after giving the establishment an opportunity to be heard. Every element of that sentence is examinable and each can be dismantled in a stem.

Learn the structure element by element. The trigger is non-compliance with, or wilful neglect of, an order, not any breach at all. The response is discretionary, expressed as a permissive *may* and not a mandatory *shall*, so a script that makes the penalty automatic has overstated the law; this is exactly the modal error that turns a discretionary power into an invented duty. The monetary sanction is capped and not fixed, so the words up to are doing real work and the body is not obliged to levy the maximum. And cancellation of registration is gated behind a hearing, which keeps the enforcement power itself within the discipline of due process. Collapse any one of those - read the discretion as a duty, drop the ceiling, or forget the hearing - and you have described a harsher and different law than the one the Act actually writes.

8.6 The Board in day-to-day practice

Where the treating psychiatrist meets the Board. For the clinician the Board is not an abstraction. It is the body that can be asked to review a decision they have made, and it is also a body a psychiatrist may sit on, so the specialty stands on both sides of the process. When you admit a person on an involuntary, supported basis, that decision is reviewable by the Board on an application from the person, their nominated representative or another interested person, and the quality of your documentation is precisely what will be scrutinised if the decision is challenged. The Board decides on the record that exists, and a decision that was clinically sound

but poorly recorded is hard to defend once it reaches the bench. The same forum is where a contested advance instruction, or a dispute over who should act as a person's representative, is finally resolved, so the Board runs through a great deal of routine practice even when no one is thinking about it.

GOOD TO REMEMBER

If an involuntary admission is likely to be contested, prepare for the Board at the moment you admit, not when the notice arrives. Record the indication, the capacity finding and the less-restrictive alternatives you weighed, and confirm that a nominated representative is identified. Approaching the admission as something you may later have to justify before a judge-led bench, rather than as a purely clinical act, is the single habit that protects both the patient's rights and your own position.

73	74	82
CONSTITUTION OF THE BOARD	COMPOSITION OF THE BOARD	POWERS AND FUNCTIONS

The Mental Health Review Board is the Act's quasi-judicial guardian of the individual patient: constituted by the State Authority on a centrally prescribed template, chaired by a District Judge, a qualified officer of the State judicial service, or a retired District Judge, presiding over a mixed bench of administrative, clinical and lived-experience members, and empowered to hold advance directives, appoint nominated representatives, review involuntary care and enforce its orders by penalty.

9 · Central and State Mental Health Authorities

A statute of rights needs an office to enforce it. The Mental Healthcare Act sets out an ambitious charter - a capacity-based test for treatment decisions, advance directives, admission safeguards and a right to community living - but a charter on paper is only as strong as the administrative body that registers the services meant to deliver it, writes their standards and inspects them. The Act supplies that body in a deliberately two-tier form: a **Central Mental Health Authority** for the Union and a **State Mental Health Authority** in every State. Between them they are the regulatory and administrative spine of the Act, the machinery through which registration, quality norms, supervision, the workforce registers and training are actually delivered.

Marks cluster here for a reason the topic makes plain once you see its shape. There is a mandatory establishment duty with a fixed time-limit; a composition set by statute that seats particular officers and senior professionals, and deliberately seats service users too; a closed list of statutory functions; and, most examinable of all, a clean federal division of registration between the two tiers. None of it is discretionary decoration. The Authority is where the Act's principles are turned into an inspected, registered, standard-bearing system, and a candidate who can separate what the Central body does from what each State body does, and both from the case-by-case work that belongs to another body, has the topic in hand.

9.1 Where the Authorities sit: the regulator, not the adjudicator

The Act creates two quite different kinds of body and it is essential not to blur them. The Central and State Authorities are primarily administrative and regulatory: they register establishments, write the norms those establishments must meet, supervise them, hold the registers of the workforce, and train and advise. The case-by-case, quasi-judicial function - examining whether a particular admission is lawful, reviewing an advance directive, hearing a person's application against a decision made about him - belongs to the Mental Health Review Board, a separate body constituted under the Act and treated in its own right elsewhere in this chapter. That division is not absolute both ways, though: a rights complaint about deficiencies in care can escalate from the Board to the State Authority as the final statutory tier where the complainant remains dissatisfied, and both Authorities also carry their own power to inspect, inquire into and act on rights violations. The Authority builds and polices the system and stands as the last statutory word on a dissatisfied complaint; the Board adjudicates the individual case within it.

The second organising idea is federal. Public health is principally a State subject, but mental-health legislation also draws on the Concurrent List, which is why both the Union and the States can legislate here, and the Act reflects that by mirroring its structure at two levels rather than centralising it. The Central Authority governs the services under the Union's control; each State Authority governs the services within its State. The two are built on the same template - an establishment duty, a fixed composition, a list of functions - so the efficient way to learn them is as one design instantiated twice, with the differences (who chairs, who sits, and above all who registers what) as the examinable delta.

RULE **The Authorities regulate the system; the Review Board adjudicates the individual case.** Registration, norms, supervision, the workforce registers, training and advice are the Authorities' work; deciding whether a particular admission or advance directive is lawful is the Board's. Sort any question first by asking whether it concerns the standing of a service or the standing of one patient's decision, and the right body follows.

TRAP **Naming the Authority where the answer is the Review Board, or the reverse.** Registering a nursing home, framing service norms or maintaining a register of clinical psychologists is Authority territory; reviewing an involuntary admission, examining an advance directive or hearing a patient's application is the Board's. Both are created by the same Act, and under time pressure candidates swap them. State which function is in play and the body chooses itself.

9.2 The Central Mental Health Authority: the establishment duty (section 33)

The Act does not merely permit a Central Authority; it commands one. The Central Government shall, within **nine months** of the Act receiving the assent of the President, by notification establish the Central Authority for the purposes of the Act. Read the modal verb with care, because it is the kind of distinction the whole chapter turns on: the provision says the Government *shall* establish, not that it *may*. This is a positive statutory obligation carrying a fixed outer time-limit, not a discretionary power the executive is free to leave unused.

Two phrases in the provision do quiet work. "By notification" tells you how the body comes into legal existence - it is constituted on publication in the official gazette, not by mere executive

intention - and "for the purposes of this Act" fixes its remit to the Act's own scheme rather than to mental health administration at large. The point to carry is that the existence of the regulator is itself a legal duty with a clock on it. An Act that created rights but left their enforcement machinery optional would be hollow; by making the Authority mandatory and time-bound, the statute guarantees that the body responsible for registering and standardising services must exist, and must exist promptly.

9.3 Composition of the Central Authority (section 34)

Who sits on the Authority is fixed by statute, not left to the Government to compose at will. It is chaired **ex officio** by the Secretary or Additional Secretary in the Department of Health and Family Welfare - that is, the chair is held by whoever occupies that administrative post, by virtue of the office rather than by personal nomination. Alongside the chair sit a set of named ex officio members drawn from the relevant arms of government, and then the nominated members who give the body its professional and lay expertise.

The nominated professional members are the part examiners test. They include a **mental health professional**, a psychiatric social worker, a clinical psychologist and a mental health nurse, each required to have at least **fifteen years** of experience in the field. The seniority bar is deliberate: the people writing service norms and supervising establishments are meant to be seasoned practitioners rather than junior appointees. Just as deliberately, the composition reserves places for representatives of persons who have or have had mental illness, of care-givers and of non-governmental organisations. Seating service users and care-givers on the regulator itself is a design choice, not an afterthought - it is the participatory, rights-based logic of the Act made structural, so that the body standardising services is not composed only of officials and clinicians.

33	43	45	55
CENTRAL AUTHORITY ESTABLISHED	CENTRAL AUTHORITY FUNCTIONS	STATE AUTHORITY ESTABLISHED	STATE AUTHORITY FUNCTIONS

9.4 Functions of the Central Authority (section 43)

The Act sets out what the Central Authority shall do as a defined list of duties, and the verb throughout is mandatory. The functions are best held as a small set of roles the body performs across the services under the Union's control:

- register every **mental health establishment** under the control of the Central Government, and maintain a register of all such establishments in the country;
- develop **quality and service provision norms** for the different types of establishment it oversees;
- supervise those establishments and receive complaints about deficiencies in the services they provide;
- maintain a **national register** of clinical psychologists, mental health nurses and psychiatric social workers;
- train all relevant persons - including law-enforcement officials, mental health professionals and other health professionals - in the provisions and implementation of the Act; and

- advise the Central Government on all matters relating to mental healthcare and services.

Two of these deserve emphasis. The registration function makes the Authority the gatekeeper of legitimate practice: an establishment that is not registered is not lawfully operating, and the register the Authority keeps is the country's ledger of recognised services. The workforce register does the same for people - it is the national list of the allied mental-health professions, distinct from the registration of establishments and serving a different purpose. Both are national in scope, because the Central Authority's job is aggregation and standard-setting across the Union rather than the running of any single facility.

MNEMONIC

TRANS - the regulator's five verbs

The Authority's statutory job is to **T**rain the relevant officials and professionals, **R**egister establishments and keep the workforce register, **A**dvise the Government, set **N**orms of quality and service, and **S**upervise establishments while receiving complaints. Five verbs, one regulator: the letters recover the whole functional remit without adding anything the provision does not itself contain.

GOOD TO REMEMBER

The workforce register is not an abstraction when you build a team. Clinical psychologists, mental health nurses and psychiatric social workers are registered to work as mental health professionals under the Act, and their standing in that role flows from the register. If you are staffing an establishment or referring within a multidisciplinary team, a professional's registration is what places them lawfully in the role the Act recognises.

9.5 The State Mental Health Authority: establishment and composition (sections 45 and 46)

The State tier is built on the same template, and its establishment provision mirrors the Central duty exactly in force. Every State Government shall, within **nine months** of the Act receiving assent, by notification establish a State Authority for the purposes of the Act. Again the verb is *shall*, again there is a fixed window, and again the body is constituted by notification. The obligation lies on every State without exception, so the two-tier system is meant to be complete across the country rather than a Union body with optional State counterparts.

The composition follows the Central pattern with instructive differences. The State Authority is chaired ex officio by the Secretary or Principal Secretary in the State's Department of Health. Its nominated membership again carries senior professionals - a mental health professional, a psychiatric social worker and a clinical psychologist, each with at least **fifteen years** of experience - but it also brings in explicitly clinical and academic weight that examiners like to test. It includes the head of one of the mental hospitals in the State, or the head of the department of psychiatry at a Government medical college, nominated by the State Government, together with one eminent psychiatrist from the State who is not in Government service. Seating both a senior public-sector clinician-administrator and an independent private psychiatrist

anchors the State regulator in the actual service landscape of that State rather than in officialdom alone.

9.6 Functions of the State Authority and the registration split (section 55)

The State Authority's functions parallel the Central body's, and the parallel is exactly where the single most examinable distinction in this topic appears. The State Authority shall register all mental health establishments in the State, and here the operative word is *except*: it registers all establishments in the State except those that fall under the Central Authority's registration mandate, and it shall maintain and publish a register of them, including online. It shall likewise develop quality and service norms, supervise establishments and receive complaints, register clinical psychologists, mental health nurses and psychiatric social workers within the State to work as mental health professionals, and train the relevant officials and professionals.

The registration split is the high-yield line. Put the two registration functions side by side and the federal logic is exact. The Central Authority registers the establishments under the control of the Central Government; each State Authority registers everything else within its borders. There is no overlap and no gap - a given establishment is registered by one Authority or the other, decided by whether it is centrally controlled. The State register carries the added statutory feature of being published, including online, which turns it into a public instrument a patient or family can in principle consult rather than an internal list.

AXIS	CENTRAL AUTHORITY	STATE AUTHORITY
Who must establish it	The Central Government	Every State Government
Establishment duty	Mandatory, within a fixed window from assent	Mandatory, within the same window
Chairperson (ex officio)	Secretary or Additional Secretary, Department of Health and Family Welfare	Secretary or Principal Secretary, State Department of Health
Distinctive members	Senior professional members; representatives of persons with mental illness, of care-givers and of non-governmental organisations	Head of a State mental hospital or of psychiatry at a Government medical college; one eminent non-Government psychiatrist; senior professional members
Which establishments it registers	Those under the control of the Central Government	All other establishments in the State
Register of establishments	A national register of all establishments in the country	A State register, maintained and published (including online)
Register of professionals	Maintains the national register of clinical psychologists, mental health nurses and psychiatric social workers	Registers those professionals within the State

IN INDIA

The practical effect is that no mental health establishment operates lawfully without being registered by the appropriate Authority, and the State register is a published document, available online, rather than a closed file. For a patient or family this is a real safeguard: the recognised services in a State can be identified, and a complaint about deficiencies in a service has a defined statutory destination rather than nowhere to go. For the professions, the workforce registers give the allied mental-health disciplines a formal national footing.

PITFALL

A clinician opening a private psychiatric facility who assumes the Central Authority is the body to register with has misread the split. Unless the establishment is under the control of the Central Government, it is the State Authority that registers it. Taking the application to the wrong tier wastes time and, worse, can leave a service running unregistered in the belief that it has complied. Match the establishment to the Authority by asking one question first: is this a centrally controlled establishment or not?

Both Authorities are mandatory statutory bodies that must be established within a fixed window of assent; the Central Authority registers establishments under Central-Government control while every State Authority registers all other establishments in its State, and both are regulators, distinct from the quasi-judicial Review Board.

10 · Decriminalization of suicide under MHCA Section 115

This is where the law stops treating a survived suicide attempt as a crime and starts treating it as a medical emergency. A person who lives through an attempt on their own life reaches casualty in one of the most fragile states medicine ever encounters, and the older question of whether that same person is also a criminal defendant sat awkwardly on top of the clinical crisis for most of the last century. Section **115** of the Mental Healthcare Act settles that question by statute. It does not merely voice a sentiment about compassion; it lays down a rule of evidence and a public obligation, and the examiner wants that rule stated precisely, with its correct scope and its correct verbs.

Fig 25.7 Section 115 of the Mental Healthcare Act presumes severe stress after a suicide attempt, protects the person from trial and punishment subject to the statutory rule, and places a duty on government to provide care, treatment and rehabilitation. It does not create a right to die.

The marks here are easy to shed because the provision is routinely over-stated. Candidates say the Act legalised suicide, or that the Act itself repealed the offence, and both are wrong. What the section actually does is narrower and more careful: it presumes a mental state, it bars trial and punishment, and it lays a duty of care, all without itself deleting a word of the older criminal law. That older offence, the attempt to commit suicide once punishable under Section **309** of the Indian Penal Code, is the historical provision the section is drafted around; the section decriminalises by presumption and bar rather than by repeal, and the later fate of that older Code is a separate matter taken up at the end of this topic. Holding that distinction is the whole of the question.

115	**309**	**226**
MENTAL HEALTHCARE ACT SECTION, THE OPERATIVE LAW	FORMER PENAL CODE OFFENCE, REPEALED 2024	BHARATIYA NYAYA SANHITA SECTION, THE ONLY CURRENT OFFENCE

10.1 Decriminalisation is not repeal

The single most important idea in this topic is a distinction between two things that sound alike and are not. **Decriminalisation** removes the criminal consequence that would otherwise attach to an act while leaving the underlying prohibition where it stands; **repeal** strikes the prohibition out of the law altogether. The section achieves the first and not the second. It works through a **notwithstanding clause**: the presumption and the bar on trial and punishment operate notwithstanding the older Penal Code offence, which is the legislative device for making a new rule prevail over an existing one without repealing that existing one. At the time the section was enacted the older offence therefore stayed on the book, its operation merely displaced, while a person who had attempted suicide was lifted out of its reach by the presumption the section erects around them.

The reason this matters beyond pedantry is that scope follows from it. Because the section works by decriminalising one specific act and not by rewriting the criminal law wholesale, it reaches exactly as far as its own words carry it, and no further. It lifts the person who has attempted suicide out of trial and punishment; it says nothing about anyone else and nothing about any neighbouring offence. A candidate who reads the reform as a sweeping repeal has, without noticing, claimed that everything the old law touched has fallen away, which both over-states the section and is the source of the classic scope errors examined later in this topic.

RULE **The section decriminalises the attempt; the section itself does not repeal the offence.** A rebuttable presumption and a statutory bar lift the person who has attempted suicide out of trial and punishment, operating notwithstanding the older Penal Code provision rather than striking it out. Reading the section itself as a repeal over-states what it does and misplaces its limits.

10.2 The presumption of severe stress

The first working part of the section is a presumption, and its wording is exact. Any person who attempts to commit suicide shall be presumed, unless proved otherwise, to have **severe stress**, and shall not be tried and punished under the Indian Penal Code. Two features of that sentence carry the marks. First, the verb is mandatory: the person shall be presumed to be under severe stress, and shall not be tried and punished. This is not a discretion the court may exercise; it is a default the law imposes. Second, the presumption is a **rebuttable presumption**, signalled by the words unless proved otherwise. The law starts from the position that the attempt sprang from severe stress, but it leaves open the possibility that this can be displaced by proof to the contrary.

Understanding what a rebuttable presumption does to the burden of proof is what separates a precise answer from a vague one. Ordinarily the person invoking a defence must establish it. Here the statute flips the starting point: severe stress is assumed, so the effort of showing that it was absent falls on whoever wishes to argue that the person should nonetheless be tried. In practical terms this makes trial and punishment the exception rather than the rule, because the ordinary case is presumed into the protected category and stays there unless someone affirmatively proves otherwise. The legislature chose a presumption rather than a blanket, unconditional immunity for a reason: a presumption defaults every survivor into care while preserving a narrow

evidentiary route for the genuinely unusual case, without ever requiring the distressed person to prove their own distress.

One further nuance repays attention. What the section presumes is severe stress, not a diagnosed mental illness. The protection does not wait on a psychiatric label and is not confined to those who can be shown to be mentally ill; a person overwhelmed by circumstance who attempts suicide is presumed into the same protected position as one whose attempt arose from a formal disorder. This keeps the reform broad at the point where it matters, the moment of contact after an attempt, and it is why the section is drafted around stress rather than around illness. The clinician's later judgement about whether a mental illness is present shapes the care that follows, but it does not gate the presumption that shields the person from trial and punishment.

10.3 The duty to provide care, treatment and rehabilitation

The presumption is only half of the section, and a candidate who stops there has answered half the question. The second working part is an affirmative obligation. The **appropriate Government** shall have a duty to provide care, treatment and rehabilitation to a person who has severe stress and has attempted to commit suicide, so as to reduce the risk of recurrence of the attempt. Again the verb is mandatory: this is a duty the Government shall discharge, not a service it may choose to offer. Where the first part shields the person from the criminal process, the second part turns the State toward them, converting the removal of punishment into a positive commitment of care.

The triad the duty names is worth taking apart, because each word points somewhere different in time:

- **Care** is the immediate response, the safe holding and attention the person needs in the acute aftermath of the attempt.
- **Treatment** is the address of whatever underlies the severe stress, whether a mental illness, a crisis of circumstance, or both.
- **Rehabilitation** is the forward-looking limb, the work of restoring the person to a life in which the risk that brought them to the attempt is reduced.

The stated purpose of the duty, to reduce the risk of recurrence, is what ties the triad together and gives the reform its public-health character. The section is not content simply to decline to punish; it reframes a suicide attempt as an event that generates an obligation on the State to intervene therapeutically, precisely because a person who has attempted once carries a raised risk of attempting again. The presumption and the duty are therefore not two unrelated clauses that happen to share a section; they are the negative and positive faces of a single decision to move the survivor of an attempt from the criminal justice system into the care system.

MNEMONIC

Presume, do not try, then provide

The section in three moves. **Presume** severe stress in the person who has attempted suicide; **do not try** - they shall not be tried and punished under the Indian Penal Code; **then provide** - the appropriate Government shall have a duty to give care, treatment and rehabilitation to cut the risk of a repeat attempt.

AXIS	FIRST LIMB - THE PRESUMPTION	SECOND LIMB - THE DUTY
WHAT TRIGGERS IT	An attempt to commit suicide by the person	A person with severe stress who has attempted suicide
STATUTORY VERB	Shall be presumed; shall not be tried and punished	Shall have a duty to provide
NATURE OF THE RULE	A rebuttable presumption of severe stress, displaceable only by proof otherwise	A mandatory obligation, not a discretionary service
WHO IS ACTED ON	The person, who is lifted out of the criminal process	The appropriate Government, on whom the obligation falls
PURPOSE	To remove criminal liability and reframe the attempt as a mental-health event	To provide care, treatment and rehabilitation and reduce the risk of recurrence

10.4 What the section does not reach

Because the reform is so easy to over-read, the examinable core is as much about the section's limits as its content. It decriminalises the attempt by the person, and that is the boundary of what it does. It does not license **assisted dying**: the section speaks to someone who has survived an attempt on their own life, not to any right to be helped to end that life, which is a wholly separate legal and ethical question the section neither raises nor answers. Nor does it disturb the offence of **abetment of suicide**, which remains a distinct crime directed at the person who instigates or aids another's death; the protection runs to the one who attempted, not to a third party who drove them to it.

Stated as the three things the section does not do:

- It does not, by itself, repeal the older attempt-to-suicide offence; it works by presumption and bar, operating notwithstanding that offence rather than striking it out.
- It does not license assisted dying or create any right to be helped to die.
- It does not decriminalise the abetment of suicide, which remains a separate and live offence.

TRAP **The section did not itself repeal the older attempt-to-suicide offence, and it did not legalise suicide across the board.** The commonest examination error is to write that the Act struck out the attempt-to-suicide offence, or that suicide is now lawful. Neither is true of what the section does: a rebuttable presumption bars trial and punishment of the person who attempted, the section operates notwithstanding the older offence rather than deleting it, and abetment of suicide remains a crime. Collapsing a conditional presumption into a blanket repeal loses the mark every time.

PITFALL

Quoting the presumption as though it were absolute. Clinicians and candidates alike drop the words unless proved otherwise and describe the section as an unconditional immunity, so that no attempt could ever be tried and punished. The presumption is rebuttable, its protection is confined to the person who attempted, and it leaves assisted dying and abetment untouched. Stating a presumption without its condition is the same class of error as stating a statutory immunity without its conditions, and both are penalised.

The section raises a rebuttable presumption of severe stress that bars the trial and punishment of the person who attempted suicide, and it lays a mandatory duty on the appropriate Government to provide care, treatment and rehabilitation to reduce recurrence; it decriminalises the attempt by presumption and bar, working notwithstanding the older Penal Code offence rather than by repealing it.

10.5 Receiving the survivor: the clinical frame

The value of the section for a working psychiatrist is that it converts a legal principle into a default posture at the bedside. When a patient arrives after an attempt, the law has already decided, in advance and in mandatory terms, that this is a person under severe stress to be cared for, not a suspect to be processed. The clinician's task is therefore squarely medical: assess the mental state, stabilise the acute risk, identify and treat what underlies the stress, and plan for the follow-through that the rehabilitation limb contemplates. Documentation of that assessment and plan is what demonstrates that the survivor was received into the care pathway the section builds, rather than diverted into a criminal one.

Two practical points follow. First, the reflex of treating every self-harm presentation as a police matter is displaced by the section: the default is clinical care, and the record should show the mental-state assessment and the safety plan that the care pathway calls for. Second, the presumption does not dilute the clinician's own duties of assessment and risk management; if anything it sharpens them, because the person is now unambiguously a patient owed care rather than a suspect to be handed on. The section changes the frame of the encounter, not the standard of the clinical work carried out within it.

IN INDIA

Before this Act, an attempt to commit suicide was itself prosecutable under the Indian Penal Code, so a survivor could in principle be treated as an offender rather than a patient - a position long criticised as compounding distress with the threat of a criminal record. The Mental Healthcare Act reversed that default nationally, moving the survivor of an attempt from the criminal frame into a statutory presumption of severe stress backed by a Government duty of care. The everyday working knowledge that protects a patient is the simple version: the person who has attempted is presumed to be under severe stress, is not to be tried and punished, and is owed care by the State.

GOOD TO REMEMBER

On the ward, the section means the police station is not the first stop for a survivor of an attempt. Frame the encounter as an emergency, treat and document accordingly, and remember that the presumption protects the patient and the abetment law protects against those who might have driven them there - the two are not in tension. Where a case genuinely looks unusual, the burden of displacing the presumption is not yours to discharge and not the patient's to answer.

10.6 Currency, controversy and the limits of the reform

The reform is real but partial, and the exam rewards seeing both. The controversy the section itself raises is the gap between decriminalisation and repeal. When it was enacted the section decriminalised the attempt without repealing Section **309** of the Indian Penal Code; the presumption operated notwithstanding that offence, so the older crime stayed on the book but inoperative for the survivor, and commentators noted that a fuller reform would have removed it outright rather than papering over it with a presumption. The words unless proved otherwise were read by some as a residual doorway, since a presumption that can in theory be rebutted is not the same as an offence that cannot be charged at all.

The second live question is enforceability of the duty. A mandatory obligation on the appropriate Government to provide care, treatment and rehabilitation is only as strong as the services that actually exist to discharge it, and a duty framed in a statute does not by itself build the crisis care and follow-up capacity a survivor needs; the reform's ambition on the care side outruns the machinery available to deliver it. The currency point that now settles cleanly is the fate of the older offence. The Indian Penal Code was repealed and replaced in its entirety by the Bharatiya Nyaya Sanhita, 2023, in force from **1 July 2024**, so the provision the section is drafted around is no longer live law for conduct occurring on or after that date; the section's own text still refers to it, but a textual cross-reference does not keep a repealed offence in force. That repeal is not absolute for what came before it: the Bharatiya Nyaya Sanhita carries its own repeal-and-savings clause, preserving the Penal Code's previous operation, any liability or punishment already incurred under it, and any investigation or proceeding begun under it, to be continued as if the Code had not been repealed, so an attempt committed before that commencement date remains governed by the saved older position read together with this section's presumption and bar, and the law is not silent for that period. The new code did not carry over a general offence of attempting suicide. For conduct on or after that same commencement date, the only criminal

provision that now reaches an attempt is the narrow Section **226** of the Bharatiya Nyaya Sanhita, confined to the person who attempts suicide with the intent to compel or restrain a public servant from discharging his official duty, punishable with simple imprisonment which may extend to one year, or fine, or both, or community service. For the ordinary survivor of an attempt nothing in that provision applies, and the section's presumption and Government duty of care stand as the operative law. What the section itself decides is unambiguous, and that is what the answer should assert without hedging: a presumption of severe stress, a bar on the trial and punishment of the person who attempted, and a mandatory Government duty of care.

11 · Prohibited and restricted procedures (ECT, psychosurgery, restraint, seclusion)

Why the marks are here. The Mental Healthcare Act does not only decide who may be admitted and treated; it draws a hard perimeter around HOW a person with mental illness may be treated, naming a small set of interventions that are either forbidden outright or permitted only through a defined statutory gate. Examiners return to this perimeter because it is where a single modal verb settles the law. A procedure that "shall not" be done is not the same thing as one that "may only" be done on conditions, and a candidate who blurs the two has misread the Act rather than merely forgotten a detail. The territory is narrow, and the marks reward precision rather than breadth.

The scheme lives in a short, consecutive run of provisions. One lists the procedures the Act prohibits, one restricts a single neurosurgical treatment, and one governs the everyday coercive measures of restraint and seclusion. The examinable point is almost always the BOUNDARY between the categories rather than the content of any one rule, so it pays to learn the categories first and hang the detail on them. Read this topic as a small system of law, not as a list of facts to be recited.

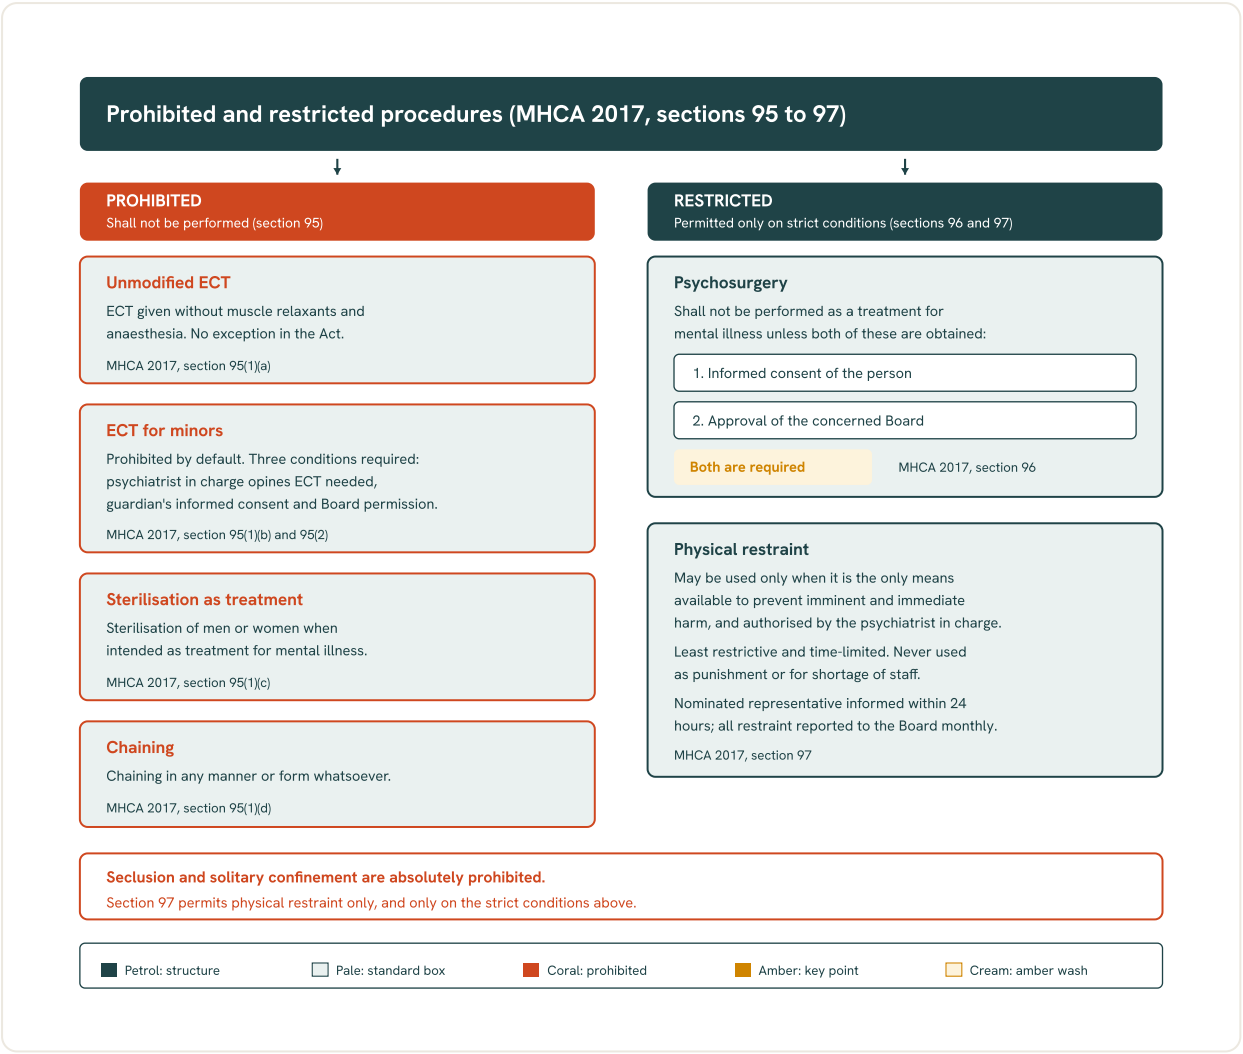

Fig 25.8. The Mental Healthcare Act 2017 separates absolutely prohibited procedures (section 95) from procedures permitted only on strict conditions (sections 96 and 97). Unmodified ECT has no exception, while ECT for minors, psychosurgery and physical restraint each pass only through a defined statutory gate, and seclusion stays barred outright.

11.1 Prohibited versus restricted: the architecture

The Act sorts controlled interventions into two families that must never be run together. A **prohibited procedure** is barred: the statute says it shall not be performed, and the only softening it permits is a single exception written into the statute itself. A **restricted procedure** is lawful, but conditionally: it shall not be performed UNLESS defined requirements of consent and authorisation have first been met. The difference is one of kind, not of degree. A prohibition is a closed door with, at most, one named key; a restriction is an open door with a lock on it, and the whole of the analysis is deciding which door you are standing at.

This architecture is not arbitrary drafting. It follows from the governing idea of the Act, that a person with mental illness keeps the ordinary rights of dignity and bodily integrity, and that any intrusion on those rights must be justified, minimised and supervised by someone outside the treating team. The interventions the Act singles out are procedures with recognised risks of coercion and misuse: given without anaesthesia, imposed on children, used to sterilise, or reached for when a ward is short of staff. Naming them in primary legislation, rather than leaving them to

professional custom, converts a matter of clinical etiquette into a matter of enforceable law that a statutory Board can review after the fact.

RULE **The category fixes the modal, and the modal fixes the law.** A prohibited procedure carries a "shall not": it is barred, and any relief comes only from an exception the statute writes for itself. A restricted procedure carries a "shall not ... unless": it is permitted, but only once the conditions of consent and Board authorisation are satisfied. Deciding which category a procedure belongs to is therefore the whole task, because the operative rule falls straight out of the category.

The accompanying table maps each controlled intervention to its category, its operative modal and the lawful route, if any, that reopens it. Read down the modal column first, because it is the fastest way to see why the same word, ECT, can name both an absolute prohibition and a conditionally permitted treatment.

PROCEDURE	CATEGORY	OPERATIVE RULE AND MODAL	LAWFUL ROUTE, IF ANY
UNMODIFIED ECT, WITHOUT MUSCLE RELAXANTS AND ANAESTHESIA	Prohibited	Shall not be performed	None
ECT FOR A MINOR	Prohibited by default	Shall not be performed	Guardian's informed consent and the Board's prior permission
STERILISATION INTENDED AS TREATMENT FOR MENTAL ILLNESS	Prohibited	Shall not be performed	None, as a treatment for mental illness
CHAINING, IN ANY MANNER OR FORM	Prohibited	Shall not be performed	None
PSYCHOSURGERY	Restricted	Shall not be performed unless conditions met	Person's informed consent and the Board's approval
SECLUSION OR SOLITARY CONFINEMENT	Prohibited	Shall not be imposed	None
PHYSICAL RESTRAINT	Restricted, conditional	May only be used when necessary and authorised	Only means to prevent imminent, immediate harm, authorised by the psychiatrist in charge

11.2 The prohibited procedures

The prohibitions are gathered in section **95**, which opens with a non-obstante clause and then states that the listed treatments shall not be performed on any person with mental illness. The non-obstante wording is doing real work: it makes this rule prevail over everything else in the same Act, so no other machinery, not an emergency, not a substitute decision-maker, not an advance instruction, can be used to authorise what the section forbids. Four interventions sit on the list:

- **unmodified electroconvulsive therapy**, meaning ECT given without the use of muscle relaxants and anaesthesia;
- electroconvulsive therapy performed on a minor;
- **sterilisation** of a man or a woman, where it is intended as a treatment for mental illness;
- **chaining** in any manner or form whatsoever.

Two features of the drafting repay attention. The bar on the unmodified technique is the statutory root of the working rule that ECT may be given in modified form only; the Act does not merely discourage unmodified ECT, it forbids it, and, unlike the position for a minor, it attaches no exception of any kind. Sterilisation, by contrast, is caught specifically when it is intended as a treatment for the mental illness itself, which is the historical eugenic use the clause is written against; it says nothing about surgery undertaken for unrelated reasons, on ordinary consent, in a person who happens to have a mental illness. Reading that qualifier out of the clause is a common way to overstate it.

The technique of ECT itself, its electrode placement, stimulus dosing, seizure threshold and mechanism, belongs to **the ECT and neurostimulation notes**; here the Act speaks only to whether, and on whom, the procedure may lawfully be performed at all. The full consent procedure and eligibility rules for ECT, including the modified-only requirement as an operating standard, are developed where this chapter sets out the Act's ECT provisions. This section fixes only the placement of ECT within the prohibited-and-restricted scheme, and no more.

IN INDIA

The explicit bar on chaining a person in any manner or form is not a theoretical clause. It responds to documented reports of persons with mental illness being chained in Indian homes, custodial settings and faith-healing establishments; how widespread or prolonged the practice was is not itself something section **95** establishes. By naming the practice in primary legislation and placing it among the treatments that shall not be performed, the Act converts what had been tolerated as a family or community coping measure into an unlawful act, and hands inspecting authorities a bright line rather than a matter of degree to argue over.

MNEMONIC

The prohibition list: Unmodified ECT, Minor's ECT, Sterilisation, Chaining

These are the treatments the prohibited-procedures section forbids by default, in the order the Act lists them. The first admits no exception, and neither does the last; a minor's ECT alone reopens, through the proviso that follows, and sterilisation is caught only where it is meant as a treatment for the mental illness itself. If you can rebuild the list, you can rebuild the section.

11.3 The single conditional exception

One item on the prohibition list, and one only, is reopened by the Act. Electroconvulsive therapy for a minor is barred by default, but a proviso to the same section provides that, where the psychiatrist in charge of the minor's treatment is of the opinion that it is required, the treatment

shall be done with the informed consent of the guardian and the prior permission of the concerned Board. The consequence for the taxonomy is the point to carry away here: this is not a flat prohibition like the others but a prohibition with a single, fully conditioned gate, which is exactly why it must be read alongside its proviso and never quoted as an outright ban.

The mechanics of that gate, how the guardian's consent is taken, what the Board must weigh, and the requirement that its permission come before rather than after the treatment, are the province of this chapter's ECT-provisions material, which owns the consent-and-eligibility rules in full; they are named here only to place the exception inside the prohibited category. What this section contributes is the discrimination itself: an absolute bar admits no consent, a conditionally reopened bar admits a defined one, and the two ECT rules sit on opposite sides of that line even though they share a name. A candidate who carries "ECT is prohibited under the Act" as a single fact has flattened two different rules into one.

11.4 The restricted procedure: psychosurgery

Psychosurgery is handled separately, in section **96**, and it is the cleanest example the Act gives of a restricted procedure. **Psychosurgery** shall not be performed as a treatment for mental illness UNLESS two requirements have both been obtained: the informed consent of the person on whom the surgery is to be performed, AND the approval of the concerned Board. The conditions are conjunctive. The patient's consent does not stand in for the Board's approval, and the Board's approval does not stand in for the patient's consent; each is necessary and neither is sufficient alone. That is precisely what makes this a restriction and not a prohibition: the door is open, but it carries two locks and both must be turned.

The scope of the provision is a favourite trap, and it is worth stating flatly. The psychosurgery restriction governs psychosurgery, and psychosurgery only. It does not reach ECT, and there is no separate "ECT machinery" hiding inside it: every ECT rule lives in the prohibited-procedures section and its minor-treatment proviso, not here. A candidate who files ECT under the psychosurgery restriction, or who imports the psychosurgery consent conditions into the ECT analysis, has crossed a boundary the Act keeps deliberately sharp. The two provisions are neighbours in the statute and strangers in their content.

The contrast with the prohibited category is the deeper teaching point. Psychosurgery is not forbidden; a person who retains the capacity to consent may lawfully undergo it, provided the Board agrees. The informed consent the section demands is meaningful only in a person with the capacity to give it, a standard the Act defines where this chapter treats capacity to make treatment decisions, and which is presupposed rather than restated here. That is the whole logic of a restricted category: the Act judges the procedure too grave to leave to consent alone, but not so grave as to bar it outright, and so it inserts an independent gatekeeper between the clinician's proposal and the operating table.

11.5 Restraint and seclusion

The last provision, section **97**, governs the two coercive measures a ward reaches for in an emergency, and it treats them very differently. **Seclusion** and solitary confinement are prohibited

outright: a person with mental illness shall not be subjected to them, with no gate at all. **Physical restraint** is not banned but tightly restricted; it may only be used when it is the only means available to prevent imminent and immediate harm to the person or to others, AND when it is authorised by the psychiatrist in charge of that person's treatment. The modal split is the heart of the section, and it is asymmetric on purpose: seclusion attracts a flat "shall not", while restraint attracts a "may only ... when". Both conditions on restraint, the necessity test and the authorisation, are cumulative; neither alone will do.

Restraint, once permitted, is then hedged by a set of continuing duties that make it an accountable act rather than a clinical convenience:

- it shall not continue for any period longer than is absolutely necessary to prevent the immediate risk of significant harm, and it shall never be used as a punishment or a deterrent, nor reached for merely because the establishment is short of staff;
- the nominated representative shall be informed of every instance within **twenty-four hours**, and every instance shall be included in the establishment's report to the concerned Board on a monthly basis.

Read together, these duties describe restraint as something that must be necessary, proportionate, authorised in a named clinician's own judgement, time-limited to the actual risk, purpose-limited, disclosed promptly to the person's own safeguarder, and audited from outside. The nominated representative named in these duties is the person appointed under the Act to protect the patient's interests; that office is set out where this chapter treats the nominated representative, and is only invoked here rather than defined. The point that examiners press is that the duties survive the emergency: a restraint that was clinically defensible at the moment it began is still a breach of the section if it outlasts the risk, or goes unrecorded, or is never notified.

The clinical craft of managing the violent or highly aroused patient, the graded response of de-escalation, offered medication, rapid tranquillisation and the longer-term plan, is taken up where this chapter addresses the management of the high-risk patient. That clinical decision, however, is bounded at every step by this section. A restraint that is clinically reasonable but exceeds the statutory limits is still unlawful, and seclusion is not available as a de-escalation option at all, however tempting a quiet locked room may look on a stretched ward.

TRAP **Treating restraint and seclusion as one regime, or reversing which of them is barred.** The section does not restrict the two equally. Seclusion and solitary confinement are prohibited outright, while physical restraint is conditionally permitted. A candidate who writes that "restraint and seclusion may be used in an emergency" has merged a flat prohibition with a conditional permission and stated the law of neither correctly. Answer them apart: seclusion is out, restraint is in on conditions.

GOOD TO REMEMBER

For every episode of physical restraint, run the same discipline downstream. Authorise it in your own name as the psychiatrist in charge, stop it the moment the immediate risk has passed, tell the nominated representative within the statutory window, and enter it in the monthly return to the Board. Build these into a standing ward protocol rather than trusting memory in a crisis, because the commonest failures are not of judgement at the bedside but of the notification and reporting duties afterwards. A restraint that was defensible but undocumented is, on the section's own terms, still a breach.

PITFALL

The commonest ward-level error is to treat seclusion as a milder, more respectable step than restraint, a quiet side-room rather than hands on a patient, and to use it as routine behavioural management. The Act does the opposite: it permits physical restraint under tight conditions but prohibits seclusion and solitary confinement outright, with no gate at all. Reaching for a locked room to avoid "restraining" a patient is therefore not the safer choice but the unlawful one, and it is exactly the kind of practice a Board review is designed to surface.

11.6 Reading the perimeter: modal verbs, currency and scope

Where candidates lose the mark. Almost every error on this topic is one of three kinds, and all three come from reading the statute loosely rather than exactly. The first is a modal error: softening a "shall not" into a "may not", or hardening a "may only" into a flat permission. A discretionary power and a mandatory duty are different laws, and the Act chooses its verbs deliberately; the difference between seclusion's "shall not" and restraint's "may only" is the difference between a bar and a licence. The second is a category error: collapsing the prohibited and restricted families into one, so that psychosurgery is misremembered as banned or unmodified ECT as merely restricted. The third is a scope error: reading the psychosurgery restriction as though it covered ECT, or treating seclusion as a permitted lesser form of restraint.

A word on currency, because that is where the real-world pitfalls cluster. These are provisions of the current Act. Any comparison with how the earlier mental health legislation treated unmodified ECT and prolonged institutional restraint is not verified against primary-source grounding here, and should not be quoted as an established statutory contrast. When a viva turns to prohibited and restricted procedures, the safe posture is to name the current provision, state its modal verb exactly, and give any exception WITH its conditions rather than as a headline. A gate stated without its conditions earns no marks in the examination, and on a real ward it is a breach waiting to happen.

Prohibited	Restricted	Seclusion	Restraint
BARRED, WITH ONE NAMED EXCEPTION	LAWFUL ON CONSENT AND BOARD APPROVAL	FORBIDDEN OUTRIGHT	ONLY MEANS, THEN AUTHORISED

Prohibited means never, save the single statutory gate for a minor's ECT; restricted means only with the person's informed consent and the Board's authorisation; and seclusion, uniquely, is prohibited outright while physical restraint is merely restricted.

12 · ECT provisions under MHCA (consent, minors, modified ECT)

A short provision that examiners return to again and again. The Mental Healthcare Act does not leave electroconvulsive therapy to clinical judgement alone. It draws two firm lines around the treatment and places both inside its list of prohibited procedures at section **95**: electroconvulsive therapy given without anaesthesia and muscle relaxation shall not be performed at all, and electroconvulsive therapy in a minor shall not be performed either, save under a single, tightly conditioned exception. Almost everything a candidate is asked to say about ECT and the law follows from reading those two rules exactly, in the verbs the statute itself uses.

What this section governs is **consent and eligibility**: who may lawfully receive ECT, in what form, and on whose authority. It does not govern the technique of the treatment, and it does not lay out the full taxonomy of prohibited against restricted procedures, which this chapter treats in its own place. Hold both boundaries from the outset, because the two commonest ways to lose a mark here are to answer a consent question with a fact about how ECT is delivered, and to soften an outright prohibition into a mere restriction. The value of the topic is that it is small, self-contained and unforgiving of loose wording, which is exactly why it rewards precision.

12.1 The provision: two prohibitions and a proviso

The section is headed **prohibited procedures**, and it opens with a non-obstante clause: the treatments it names shall not be performed on any person with mental illness notwithstanding anything else contained in the Act. That opening does real work and is worth pausing on. A non-obstante clause makes the rule that follows prevail over every other provision of the same statute, so no other machinery in the Act - not emergency treatment, not consent given through a substitute decision-maker, not an advance instruction - can be used to authorise something this section forbids. When it says a treatment shall not be performed, it means the treatment cannot be reached by any other route the Act provides.

Two of the procedures it prohibits concern ECT: ECT given without muscle relaxants and anaesthesia, and ECT for minors. The provision lists other prohibited procedures beside these, among them sterilisation intended as a treatment for mental illness and restraint by chaining, but those belong to the wider classification of prohibited and restricted procedures set out elsewhere in this chapter and are named here only to show the company the ECT rules keep. What matters for this topic is the two-layer shape of the section: a first part that prohibits, and a second part that, opening with its own notwithstanding clause, carves a narrow exception for the minor. A candidate must read the two parts together, because the prohibition on ECT in minors is not the whole of the law; the exception in the second part is the other half, and quoting only the first half over-states the ban.

RULE **The Act permits only modified ECT, and prohibits ECT in a minor except under one fully conditioned exception.** Unmodified ECT shall not be performed at all; ECT in a minor shall not be performed either, unless the treating psychiatrist is of the opinion that it is required and it is done with the guardian's informed consent and the Board's prior permission. Everything else on this topic is an elaboration of those two sentences.

Modified	Minors	Guardian	Board
THE ONLY LAWFUL FORM OF ECT	ECT PROHIBITED BY DEFAULT	INFORMED CONSENT REQUIRED	PRIOR PERMISSION REQUIRED

12.2 Modified ECT only

The first ECT rule is the prohibition on **unmodified electroconvulsive therapy**, that is, ECT given without the use of muscle relaxants and anaesthesia. The verb is mandatory and absolute: such treatment shall not be performed. The immediate legal consequence is the point the examiner wants stated plainly. Because the unmodified form is barred, **modified electroconvulsive therapy** - ECT delivered under general anaesthesia with pharmacological muscle relaxation - becomes the only lawful form of the treatment. Reduced to the position it establishes, only modified ECT may be given.

The reason the legislature took this step is not hard to see, and stating it briefly shows the examiner you understand the rule rather than merely reciting it. Unmodified ECT produces a full motor convulsion, with the injury, indignity and fear that attend it; the modification markedly attenuates the motor convulsion and reduces musculoskeletal injury risk, addressing much of what historically made the treatment feared and misused. The Act converts what had been a standard of good practice into a rule of law with no discretion attached to it. There is, in particular, no emergency dispensation from it: however urgent the clinical situation, the section provides no lawful route to ECT without anaesthetic and relaxant cover. A clinician who cannot arrange modified ECT cannot lawfully substitute the unmodified form.

What this section does not cover. How modified ECT is actually delivered - electrode placement, bilateral against unilateral application, stimulus dosing, the seizure threshold and mechanism of action - is the clinical technique of the treatment, and it belongs to **the ECT and neurostimulation notes**, not here. This provision owns the law of consent and eligibility: it tells you that ECT must be modified and by whom it may be consented to, not how to prescribe or administer it. Keeping the consent question and the technique question apart is itself examinable, and conflating them is a common way to drift off the point.

IN INDIA

The Mental Healthcare Act settled the question nationally by making the modified form the only lawful one and the unmodified form a prohibited procedure. How widely unmodified ECT was practised beforehand, and how the Indian position compares with practice elsewhere today, are historical and comparative questions this note does not verify and leaves as a declared gap rather than an asserted fact. What is settled is the law itself: here the rule is not guidance but statute, and the everyday working version is simply that ECT in India means modified ECT.

PITFALL

Treating direct ECT as a permissible fallback when anaesthetic cover is hard to arrange. In resource-limited settings the temptation is to reason that some ECT is better than none and to give it unmodified in an emergency. The Act allows no such reasoning: the prohibition on unmodified ECT is absolute and carries no emergency exception. The lawful response to unavailable anaesthetic support is to arrange it or to defer the treatment, never to fall back on the prohibited form.

12.3 ECT in a minor: prohibited, then conditionally permitted

The second ECT rule is the one most often mis-stated. By default, ECT for a **minor** - a person who has not attained the age of majority, as the Act defines the term - shall not be performed; it sits in the prohibited list alongside unmodified ECT. But the section does not stop there. Its second part opens with its own notwithstanding clause and creates an exception: if, in the opinion of the psychiatrist in charge of the minor's treatment, ECT is required, then such treatment shall be done with the informed consent of the guardian and the prior permission of the concerned Board. The prohibition and the exception are two halves of one rule, and a precise answer states both.

The exception is **cumulative and conditional**: it is not enough to satisfy one of its requirements, and the requirements are not interchangeable. Three conditions must be met together before ECT in a minor becomes lawful:

- the psychiatrist in charge of the minor's treatment must be of the opinion that ECT is required - a clinical-necessity filter that turns on the treating psychiatrist's judgement, not on any clinician's view and not on the family's wish;
- the **guardian** must give **informed consent** - because a minor cannot give valid consent to the treatment, consent is exercised on the minor's behalf by the guardian, and it must be informed rather than merely obtained;
- the **concerned Board** - the Mental Health Review Board with jurisdiction over the case - must grant its permission, and that permission must be prior, sought and given before the treatment is administered rather than ratified afterwards.

Each condition carries a mandatory verb: the treatment shall be done with the guardian's consent and the Board's permission. The word that trips candidates is prior. The Board's role here is a genuine external check placed ahead of the treatment, not a paperwork step completed later, and an ECT course begun in a minor on the strength of guardian consent alone, with the Board approached afterwards or not at all, is unlawful however sound the clinical indication. The design is deliberate: ECT in a developmentally vulnerable minor is a high-stakes decision, so the law layers three different safeguards - a clinical judgement of necessity, a surrogate's informed consent, and an independent authority's prior sanction - and it requires all three to align before the treatment may proceed.

MNEMONIC

Opinion, Guardian, Board

The three cumulative gates for lawful ECT in a minor, in the order the section sets them. **Opinion** - the psychiatrist in charge is of the opinion that ECT is required; **Guardian** - the guardian gives informed consent on the minor's behalf; **Board** - the concerned Board grants prior permission before treatment begins. Miss any one of the three and the treatment is not lawful.

ECT SCENARIO	POSITION UNDER SECTION 95	STATUTORY FORCE
UNMODIFIED ECT, WITHOUT MUSCLE RELAXANTS AND ANAESTHESIA	Shall not be performed; only modified ECT is lawful	Absolute prohibition, no exception
ECT FOR A MINOR, BY DEFAULT	Shall not be performed	Prohibition
ECT FOR A MINOR, WHERE THE TREATING PSYCHIATRIST IS OF THE OPINION IT IS REQUIRED	Shall be done with the guardian's informed consent and the concerned Board's prior permission	Mandatory conditional exception, all conditions cumulative

TRAP **ECT is not absolutely banned in minors, and guardian consent alone does not make it lawful.** The classic error is to write that the Act forbids ECT in minors outright, forgetting the exception; the near-miss error is to remember the exception but to give only the guardian's consent, omitting the Board's permission. Both lose the mark. The lawful route needs the treating psychiatrist's opinion of necessity, the guardian's informed consent and the Board's prior permission, together and in advance.

12.4 Informed consent for ECT generally

Away from these two special rules, ECT is not a law unto itself; it is subject to the ordinary requirement of informed consent that governs any treatment under the Act. General informed consent applies to ECT as it applies to any other intervention, and the practical shape of the consent question follows the person's capacity and status rather than anything peculiar to ECT. For an adult who has the capacity to make the treatment decision, ECT requires that person's own informed consent, freely given on an adequate disclosure of what is proposed. Where the person's capacity is impaired, the Act's answer is support rather than automatic substitution: consent is worked out with the person through the nominated representative, not simply taken over from them.

The capacity standard itself, the ability to make a mental-healthcare treatment decision, is the Act's general test, and this chapter teaches it in its own place with the definition of mental illness and of capacity; ECT does not carry a special test of its own. Likewise the support-based routes the Act provides, the nominated representative and any valid advance directive, are treated elsewhere in this chapter and are named here only to complete the picture. The point to carry away is that the consent question forks by the person in front of you:

- a capacitous adult consents for themselves;

- an adult who lacks that capacity is supported by the nominated representative in reaching a decision rather than routinely bypassed by it: the representative gives consent on the person's behalf only in the narrow case where the person needs near-total support, and even then the person's capacity is kept under frequent review; a valid advance directive guides how the person is to be treated but does not itself supply the consent, and the making and operation of both are set out separately in this chapter;
- a minor is governed by the special exception in the prohibited-procedures section - the treating psychiatrist's opinion, the guardian's informed consent and the Board's prior permission.

Why the Board sits in the loop for a minor but not for an adult. The asymmetry is instructive. A capacitous adult's own consent is treated as sufficient authority for ECT; a minor cannot consent, the guardian's consent is a surrogate rather than the patient's own, and so the law adds an independent authority to check the decision before it is acted on. The Board's prior permission is the safeguard that compensates for the fact that the person receiving the treatment is not the person consenting to it.

> Only modified ECT may be given, because unmodified ECT shall not be performed; ECT in a minor shall not be performed either, unless the treating psychiatrist is of the opinion that it is required and it is done with the guardian's informed consent and the concerned Board's prior permission.

GOOD TO REMEMBER

Before booking ECT for a patient who is a minor, assemble three things and put each in the record: the treating psychiatrist's documented opinion that ECT is required, the guardian's informed consent (put it in writing as good practice, though the Act does not itself prescribe a written form for it), and the concerned Board's prior permission. Because the Board's permission must precede treatment, build the lead time into the plan; it is not a form to be completed after the first session. For an adult, confirm capacity first: where it is present the person consents for themselves, and where it is impaired the nominated representative's task is to support the person's own decision, giving consent on the person's behalf only where the person needs near-total support and with capacity kept under frequent review, guided by any valid advance directive rather than proceeding on the family's say-so alone.

12.5 Prohibited against restricted: keeping the categories apart

A recurring error on this topic is to blur the category the two ECT rules belong to. Both live among the Act's prohibited procedures, the strongest category, in which the treatment either may not be performed at all, as with unmodified ECT, or may not be performed on the class in question except under a defined exception, as with ECT in minors. That is a different and stronger thing than a restricted procedure, where a treatment is permitted but hedged with conditions. The full account of which procedures are prohibited and which are restricted, and the statutory limits on restraint and seclusion, is given elsewhere in this chapter; the reason to raise it

here at all is that the eligibility of ECT cannot be stated correctly without placing it in the prohibited category and not the restricted one.

The discrimination matters clinically as much as verbally. Calling the ECT rules a restriction implies a general permission subject to conditions, which invites the mistake of treating the conditions as procedural hurdles a determined clinician can work around. Calling them what they are, prohibitions - one absolute and one subject to a single narrow exception - keeps the emphasis where the statute puts it: on what may not be done, and on the exact and cumulative conditions under which the one exception opens.

12.6 Currency, controversy and the examination frame

The examinable heart of this topic is verb discipline. A statute is not a gist; it is an exact rule with an exact modal verb. Here the operative verbs are shall not be performed for the two prohibitions, and shall be done with for the conditions of the minor exception, and both are mandatory. Reading a discretionary may where the Act writes a mandatory shall changes the law: it would turn a prohibition into a matter of clinical choice and the minor's safeguards into optional courtesies. State the verbs as they stand and the answer is secure; soften them and it collapses.

Two honest limits belong in a complete answer. First, the age at which a person ceases to be a minor for the purposes of this section, and the separate provision that carries the Act's general requirement of informed consent to treatment, are matters of definition that this topic points to rather than fixes; where a figure or a cross-section is not certain, the disciplined move is to name the provision and not to invent its number. Second, the boundary with the technique of ECT is a boundary of scope, not of importance: electrode placement, dose and mechanism are as clinically weighty as the consent rules, but they are decided in the ECT and neurostimulation notes, and importing them here answers a different question. What this section decides is narrow and firm, and that is what an answer should assert without hedging: modified ECT only, ECT in minors prohibited save under the three cumulative conditions, and general informed consent for everything else.

13 · Comparison of MHCA 2017 with Mental Health Act 1987

Why the marks are here. A recurring short-note and viva task asks you to set the mental health statute a psychiatrist practises under today against the one it displaced. The examiner is not testing whether you can recite two indexes of provisions; the examiner is testing whether you grasp that Indian mental health law changed its philosophy. The **custodial** statute of **1987** existed to regulate institutions and to manage people the law treated as unable to decide for themselves; the statute of **2017** exists to presume capacity and to restore rights. Almost everything that separates the two Acts follows from that single reorientation, and an answer that names the reorientation earns the marks that a list of differences never will.

It helps to read the comparison as a question about what a mental health law is for. The older Act answered: to protect society and the patient by controlling where treatment happens and who may consent on the patient's behalf. The current Act answers: to protect the person's autonomy

and dignity, treating mental illness as a health condition and not as a legal status that strips the person of a voice. Hold those two purposes side by side and the specific provisions, on capacity, on the patient's forward wishes, on who represents them, on self-harm, on treatments of concern, and on who supervises the system, sort themselves into a single pattern rather than a heap of facts to be memorised.

1987	2017
MENTAL HEALTH ACT, REPEALED	MENTAL HEALTHCARE ACT, IN FORCE

13.1 The law that was replaced

To compare fairly you have to be honest about what the earlier Act was, rather than caricaturing it. The Mental Health Act of 1987 is generally described as itself a reform in its time, one that displaced a colonial lunacy law and added procedural safeguards around admission and discharge that its predecessor had lacked. Its organising idea, though, remained custodial: the statute was built around the licensed institution and around **guardianship** and the management of the patient's property. Mental illness, on this model, sat close to a legal status, a condition that removed the person from ordinary decision-making and put the State, the court and the family in the role of custodian.

Three features of that design, as the 1987 Act is generally described, are worth naming, because each is precisely what the later Act would invert. First, the centre of gravity was the establishment: the law's energy went into licensing and inspecting psychiatric hospitals and nursing homes, so that the regulation of places stood in for the empowerment of persons. Second, decisions were routed away from the patient, whether to a guardian appointed through a court-linked process or to the receiving institution. Third, admission and detention were the pivotal legal events, and the person's own account of what they wanted carried little formal weight. The criticism that gathered against this model was not that its safeguards were absent but that its premise was wrong:

- it equated a diagnosis with an inability to decide, instead of testing the decision itself;
- it gave the person no way to record, in advance, how they wished to be treated in a future episode;
- it left the choice of surrogate to law and family rather than to the patient;
- and it treated confinement as the natural mode of care rather than the exception.

Under the older regime an admission often turned on an order obtained through a magistrate, an institution-centred route that expressed the custodial premise. The detail of those procedures is now of historical interest only, because the Act that contained them has been taken off the statute book entirely, and it is that removal, not any single provision, which the comparison is really about. A caution belongs on the record here: the specific 1987 provisions set against the current Act in this note, including those in the table that follows, are the established historical account of the earlier statute and were not re-verified against the 1987 primary text in this pass, so read that

older column as the standard description rather than as freshly checked primary law; what is firmly grounded is the load-bearing point that the 2017 Act repealed and replaced the 1987 Act.

13.2 The paradigm shift: from custody to capacity

The current Act reorganises all of this around the person's decision-making capacity. Where the older law asked whether a person was mentally ill and, if so, who should decide for them, the newer law asks whether this person can make this particular decision and, if not, how they can be supported to. This is what is meant by calling it a **rights-based** and **capacity-based** framework: rights-based because it begins from the entitlements of the person rather than the powers of the institution, and capacity-based because the trigger for any substituted decision is a loss of capacity for a specific decision, not a diagnostic label. It is expressly aligned with the **UN Convention on the Rights of Persons with Disabilities**, the international standard for how the law should treat persons with disabilities, mental illness among them.

That alignment is the deepest of the differences, because it changes the default. In a custodial statute the default is intervention, and the person must be rescued from it by safeguards; in a rights-based statute the default is the person's own choice, and intervention is what must be justified. Every downstream contrast, the presumed capacity, the forward voice, the chosen representative, is an expression of that reversed default.

RULE **Read the two Acts as two models, not two indexes.** The Mental Healthcare Act 2017 is not the Mental Health Act 1987 with better sections; it is a different theory of what the law is for. Once you see the move from a custodial, institution-centred statute to a rights-based, capacity-based one, every specific difference becomes predictable rather than something to be recalled cold.

IN INDIA

The reform had a specific legal trigger. India is a party to that convention, and a state that ratifies one takes on a duty to bring its domestic law into conformity with it. A statute organised around custody and guardianship could not be squared with an instrument built on legal capacity and autonomy, so the real question was never whether to reform the 1987 Act but whether to amend or replace it, and only replacement could carry a change of premise. This treaty origin is why the current Act reads less like a hospitals-and-services law and more like a charter of rights for persons with mental illness.

13.3 A repeal, not an amendment

The mechanism by which the change was made carries its own teaching point. The 2017 Act does not tinker with the 1987 Act; it **repeals** it outright and puts a new statute in its place, the repeal being effected by an express repealing provision written into the 2017 Act itself. An amendment leaves the parent Act standing and edits it; a repeal-and-replace lifts the parent Act off the statute book completely and starts again. The examiner who asks for a comparison is implicitly asking you to notice this: the earlier Act is repealed for current substantive operation, subject to the extensive transitional savings the repealing provision itself carries.

Why does a repeal rather than an amendment fit a change of paradigm? Because when the organising premise of a law changes, editing individual provisions cannot carry the load. The definitions, the procedures, the bodies and the rights all have to be rebuilt around the new premise, and a patchwork of amendments to a custodial Act would leave the custodial scaffolding standing beneath them. Replacing the whole structure is the only way to make capacity, and not custody, the load-bearing idea. This is also why the answer should never present the two statutes as coexisting alternatives: one has wholly succeeded the other.

The Mental Healthcare Act 2017 did not amend the Mental Health Act 1987; it repealed and replaced it, exchanging a custodial licensing-and-guardianship regime for a rights-based, capacity-based one aligned with the UN disability convention.

PITFALL

Because the whole of the earlier Act went, a provision remembered from the 1987 framework is not a fallback when the 2017 machinery feels unfamiliar. Reaching for an institution-licensing route, or defaulting to a family guardian's consent because that is how one was taught, is to apply a law that no longer exists. When a current mechanism is unclear the answer is the correct 2017 provision, not the repealed predecessor, except for the narrow band of pre-commencement matters the repeal's own transitional savings keep alive; citing a superseded section as though it governs ordinary current practice is the way a presentation slip becomes a factual error.

13.4 The concrete markers of the shift

With the model clear, the specific novelties of the current Act become legible as instances of one move, and each is best learned as a contrast with the position it replaced rather than as a free-standing fact. The Act begins from a **presumption of capacity**, so that a person is taken to be able to make their own treatment decisions unless an assessment of the specific decision shows otherwise; the older law, by contrast, let the diagnosis do the work that a capacity assessment should do. It gives statutory standing to the **advance directive**, a person's recorded instruction about how they wish, or do not wish, to be treated in a future episode when they may be unable to say so, a forward voice the 1987 Act simply did not provide. It replaces the imposed guardian with the **nominated representative**, a person the patient may appoint themselves or, absent an appointment, one identified through the Act's own default order of representatives, to support them and, where needed, to speak for them.

The shift reaches into the treatment of self-harm and of treatments of concern as well. The current Act decriminalises the suicide attempt, directing a person who has attempted suicide towards care rather than prosecution and reversing the older exposure to the criminal law. It prohibits electroconvulsive therapy in its unmodified form, bringing a treatment the earlier statute did not specifically regulate under an explicit statutory bar; the clinical technique of that treatment is not the concern of this comparison and belongs to the ECT and neurostimulation notes. And where the older law licensed and inspected psychiatric hospitals and nursing homes through its licensing authorities, the registration and regulation of establishments now sits with

the Central and State Mental Health Authorities, so that regulatory function passes from one administrative body to its statutory successor rather than disappearing. Separately from that regulatory line, and not as a replacement for it, the current Act adds the **Mental Health Review Boards** as a quasi-judicial rights-review mechanism the 1987 framework had no equivalent of, so the genuinely new element here is the review of rights and not any transfer of the licensing function to a board. Each of these has its own detailed machinery, taught in this chapter where the Act's provisions are set out one by one; here they matter only as the visible edges of the single underlying move.

WHERE THEY DIFFER	MENTAL HEALTH ACT 1987	MENTAL HEALTHCARE ACT 2017
Governing idea	Custodial and institution-centred	Rights-based and capacity-based
Decision-making	Incapacity inferred from the illness	Capacity presumed until assessed otherwise
Patient's forward voice	None provided	Advance directive
Surrogate decision-maker	Guardian set by law and family	Patient-appointed, else statutory default order
Attempted suicide	Exposed to the criminal law	Decriminalised and directed to care
Unmodified ECT	Not specifically regulated	Prohibited
System oversight	Licensing authorities	Central and State Mental Health Authorities

MNEMONIC

DANCER - the six things the 2017 Act brought that the 1987 Act did not

Decriminalised suicide attempt, **A**dvance directive, **N**ominated representative, **C**apacity presumed, **E**CT in its unmodified form prohibited, **R**eview Boards as a new rights-review mechanism. The value of the mnemonic is that every letter is the same move seen once more, from custody towards capacity, so if you recall the theme the six recover themselves rather than having to be held as a list.

13.5 What did not change, and statute against reality

Where the contrast is easy to overstate. A good answer resists the temptation to make the two Acts opposites in every respect. The State's protective role did not vanish. The current Act still allows treatment and admission without the person's contemporaneous consent in defined circumstances, through its supported route, so the power to intervene for a person who cannot presently decide survives. What changed is that the power is now hedged with capacity assessments, a representative, review and time limits rather than exercised as custodial discretion. The continuity is deliberate: a purely libertarian statute that never permitted involuntary care would fail the very people the law exists to protect, and recognising this is what separates a mature answer from a slogan.

The harder continuity is between statute and service. A rights-based law presumes an infrastructure, review boards that actually sit, representatives who are available, directives that are honoured, community services that make non-custodial care real, and that infrastructure is uneven across the country. The most substantial criticism of the current Act is therefore not of its philosophy but of the distance between its promises and the resources on the ground, so that some of its rights remain aspirational in practice. For the exam this is the note to close on: the paradigm shift is real and is the correct headline, but its realisation is a work in progress. On currency, be unambiguous. The current Act is the operative mental health law; the 1987 Act is repealed for current substantive operation and survives only through its own narrow transitional savings, so any statement of the present general law must be drawn from the newer statute.

GOOD TO REMEMBER

The change is not academic at the bedside. A clinician trained under the older frame has to unlearn two reflexes: treating a diagnosis as automatic proof that the patient cannot decide, and treating a family member as the default consent-giver. Under the current Act the starting point is the patient's own presumed capacity, the patient's own advance instructions, and a representative the patient has chosen or, absent that, one identified through the Act's own default order, and the burden sits on the clinician to show why any of these should be displaced.

13.6 Framing the comparison in an answer

Because this topic is examined as a comparison, how you organise the answer matters almost as much as its content. Lead with the paradigm shift stated in a single sentence, then name the repeal-and-replacement so the reader knows the older Act is wholly gone, and only after that deploy the specific differences as evidence for the shift. A short contrast arranged by theme, governing idea, capacity, the patient's voice, the surrogate, self-harm, treatments of concern, oversight, earns its place because it shows understanding, whereas a table set out by section number shows only recall and invites the very error of citing a dead provision. Round off on two honest points: that the current Act is the law, and that its rights are further along on paper than in the services meant to deliver them. An answer built this way reads as an argument about a change of model, which is exactly what is being asked, and not as a memorised inventory of two statutes placed side by side.

TRAP **Answering the comparison as a section-by-section ledger.** Candidates line up provisions of one Act against provisions of the other and produce a table with no argument in it. The examiner wants the paradigm shift stated first and the provisions used as its evidence. A bare ledger also tempts you into citing a repealed provision as if it were current, which turns a presentation weakness into a factual mistake and forfeits marks twice over.

14 · Penalties and offences under MHCA

A right that cannot be enforced is only a wish, and this is the clause that puts teeth behind the whole Act. The Mental Healthcare Act spends most of its length conferring rights, prescribing procedures and constraining what may be done to a person with mental illness, and all of that architecture would be merely hortatory if a breach of it carried no consequence. The

penalties-and-offences machinery is what converts the Act's duties into enforceable law: it names the price of non-compliance and, in doing so, tells a practitioner and an establishment that the Act's procedures are not optional. The examinable core is a single provision, the **general penalty** at section **108**, and the marks are won or lost on stating it precisely, with its correct tiers and its correct verbs.

Two words are worth separating first, because candidates blur them. An **offence** is the prohibited conduct, the doing of what the Act forbids or the failing to do what it requires; the penalty is the consequence the law attaches to that conduct. The general penalty is not a list of forbidden acts but the residual consequence clause standing behind the Act's substantive duties, ready to price a breach wherever a specific penalty has not already been written. Read that way, the topic is small, exact and highly scorable.

14.1 The general penalty clause and what a contravention is

The provision is a general penalty because it is not tied to any one duty in the Act. Its trigger is a **contravention**, and a contravention here reaches three things, not one. A person who breaches any of the following falls within the clause:

- a provision of the Act itself;
- a rule made under the Act;
- a regulation made under the Act.

This breadth is deliberate. The Act operates not only through its own sections but through delegated legislation, the rules the appropriate Government frames and the regulations the Authorities issue, and a penalty confined to the bare text of the Act would leave that delegated layer unenforceable. By reaching provisions, rules and regulations alike, the clause makes the whole regulatory scheme, down to its subordinate instruments, carry the same enforceable weight. It is the safety net beneath the entire statute.

Because it is general, it is also residual. The Act singles out at least one breach for a penalty of its own: running a mental health establishment without **registration** is given a separate, specifically tiered administrative penalty in its own provision rather than being left to the general clause. The mental model is therefore two-layered. Where the Act has written a specific penalty for a specific offence, that specific provision governs; everywhere else, a contravention falls to the general penalty. A candidate who knows only that a penalty exists, without knowing that this one is the residual clause and not the whole penalty regime, has learned half the topic.

14.2 The two-tier ladder: first and subsequent contravention

The measure of the penalty is not flat. The clause escalates, distinguishing a **first contravention** from a **subsequent contravention** and treating the repeat offender more severely. It is best learned as a ladder with two rungs. For each rung the Act sets an imprisonment measure and a fine measure, and for each it leaves the court free to impose imprisonment, a fine, or both rather than forcing a single form of punishment. What changes between the rungs is not only how high

the ceilings sit but whether the fine carries a mandatory floor at all, and that asymmetry is where the marks hide. The accompanying table lays the two rungs side by side.

MEASURE	FIRST CONTRAVENTION	SUBSEQUENT CONTRAVENTION
IMPRISONMENT	up to **six months**	up to **two years**
FINE, MINIMUM	No floor stated; a ceiling only	Not less than **fifty thousand rupees**
FINE, MAXIMUM	up to **ten thousand rupees**	up to **five lakh rupees**
COURT'S OPTIONS	Imprisonment, or fine, or both	Imprisonment, or fine, or both

108	six months	two years	five lakh
ACT'S GENERAL-PENALTY SECTION	FIRST-CONTRAVENTION PRISON CEILING	SUBSEQUENT-CONTRAVENTION PRISON CEILING	SUBSEQUENT-CONTRAVENTION FINE CEILING

The pattern the table makes visible is the point. Moving from a first to a subsequent breach, the imprisonment ceiling rises, the fine ceiling rises steeply, and, uniquely, a mandatory minimum appears on the fine for the repeat offence where none existed before. A first contravention can attract a small fine, a short custodial term, or both, at the court's discretion up to the stated caps. A subsequent contravention cannot be met with a token fine, because the fine, if imposed, must clear the floor the Act sets. The escalation is thus qualitative as well as quantitative: the second time, the law removes some of the court's leniency on the fine.

RULE **The general penalty is residual, tiered and, in its measure, discretionary.** It reaches any contravention of the Act or of a rule or regulation made under it; the quantum escalates from a first to a subsequent contravention; and for each tier the court may impose imprisonment, a fine, or both. Only the subsequent-contravention fine carries a mandatory floor. Every other limit is a ceiling the court may rise to, not a fixed sentence it must pass.

14.3 Reading the verbs: ceilings, a floor and a choice

A statute is an exact rule with an exact verb, and this clause is a small masterclass in why the verb matters. The imprisonment and fine limits are almost all expressed as amounts the punishment may extend to. That phrasing sets a **ceiling**, a maximum the court may not exceed, while leaving it free to impose anything below that maximum, including a nominal penalty, according to the gravity of the breach. It does not fix the sentence. To read a ceiling as the tariff is to misstate the law by promoting a maximum into a mandate.

Against that background, one figure behaves differently, and the difference is the examinable subtlety. For the subsequent-contravention fine, the Act says the fine shall not be less than a stated amount but may extend to a higher one. That first half is a **mandatory minimum**, a floor the court must clear if it fines at all, and it is the single mandatory quantum in the whole provision. The second half is the familiar ceiling. So the repeat fine is bounded on both sides, a floor and a cap, while every other measure in the clause is bounded only above. Holding that one

asymmetry, a mandatory floor on the repeat fine and ceilings everywhere else, is what separates a precise answer from a vague recollection of large numbers.

The third verb worth naming is the connective one. Each tier offers imprisonment, or a fine, or both, a genuine disjunction with an inclusive tail. The court is not compelled to imprison; it may fine instead, and it may do both. This is why the clause is not, as it is often misremembered, a jail provision but a graduated sentencing power in which custody is one option among two.

TRAP **An amount the punishment "may extend to" is a maximum, not a mandatory sentence, and the general penalty is never automatic imprisonment.** Candidates read the imprisonment ceilings as fixed terms and state the penalty as a definite jail sentence, or forget that the court may impose a fine instead of, or in addition to, custody. The one mandatory quantum is the floor on the repeat-contravention fine; treat every other figure as an upper limit and you will not misquote the section.

14.4 A residual clause: general versus specific penalties, and what lies outside

Two boundaries keep this topic honest, and both are scope questions of the kind this chapter tests. The first is internal to the Act. The general penalty is residual: where the Act has written a specific penalty for a specific offence, that specific provision governs and the general clause stands behind it. Treating the residual clause as the whole penalty regime, and stretching it over breaches the Act has priced separately, flattens a two-layer scheme into one.

The second boundary is external, and candidates most often trip over it because the words sound adjacent. The general penalty punishes breaches of this Act. It is a wholly different question from whether a person with mental illness who commits a crime is criminally responsible for it, which the substantive criminal law decides and the criminal-responsibility material addresses. The penalty clause is a regulatory-enforcement provision aimed at those who flout the mental-health statute; the responsibility question is a doctrine of the general criminal law aimed at the mentally ill defendant. They share a chapter and little else, and conflating the enforcement of the Act with the exculpation of the accused is a category error worth guarding against.

The general penalty is also content-blind. It does not itself say which acts are prohibited or which procedures require consent; those substantive requirements live in the Act's other provisions and are taught with the items that own them, and the clinical technique, dosing and mechanism of electroconvulsive therapy belong to the ECT and neurostimulation notes. Its role sits downstream of all of that: once a substantive duty exists somewhere in the Act, whether a rule about admission, a requirement of consent, or a limit on a procedure, this is the clause that prices its breach when no more specific price has been set.

PITFALL

Applying the general penalty to an offence the Act has singled out for its own specific penalty. Running a mental health establishment without registration is not left to the general clause; the Act gives that breach a separate, specifically tiered administrative penalty of its own. Reaching for the general penalty to describe every breach, or quoting one tier's ceiling as though it were a fixed fine, is the scope error that both loses the mark and misstates the clinician's actual exposure.

14.5 In practice: triggering the penalty and how it is enforced

Why this matters at the bedside is quieter than the numbers suggest. What actually brings a clinician or an establishment within reach of the penalty is a concrete breach of the Act's duties, not an abstract one: proceeding without a consent the Act requires, admitting or detaining a person outside the admission procedure, carrying out a procedure the Act prohibits, or operating an establishment without registration. Each of these is a contravention, and the penalty clause does not ask whether harm resulted; it asks whether the Act was followed. That is a more demanding standard than a negligence test: a clinician who caused no injury can still have contravened a procedural requirement, which is why documented compliance, not good outcomes alone, is the real protection.

The reason not to overstate the clause is that its practical bite depends on machinery outside itself: a penalty means nothing until something invokes it. The clause is best understood as the backstop that gives the Act's supervisory bodies their ultimate leverage, not as a threat hovering over routine clinical work. Stated at the height the section itself supports, and no higher, the rule is clean, and that restraint is itself examinable.

IN INDIA

The Act is central law and its penalty clause applies nationally, but a penalty on paper is only as real as the machinery that invokes it. The establishment-registration penalty and the Board's own compliance powers are administrative sanctions, enforced through the State and Central Mental Health Authorities and the Review Boards, while the general penalty alone creates criminal, prosecutable punishment. The working protection for a practitioner is therefore procedural: register the establishment, follow the admission and consent procedures, respect the rights the Act confers, and keep the record that shows you did. The penalty is the backstop, not the daily instrument.

GOOD TO REMEMBER

When you are asked, in a viva or on a ward round, what happens if the Act is breached, resist the urge to name a jail term. The honest answer names the structure: a first contravention and a subsequent contravention are treated differently, the court may fine or imprison or do both, and only the repeat fine has a mandatory floor. If the breach is running an establishment without registration, that has its own specific penalty and is not this clause at all. Getting the shape right matters more than reciting a figure.

The Act's general penalty makes any contravention of the Act, a rule or a regulation punishable, more lightly for a first contravention and more heavily for a subsequent one, with the court free to order imprisonment, a fine, or both, and a mandatory minimum falling only on the fine for a repeat breach.

The Rights of Persons with Disabilities Act 2016

15 · Salient features of RPWD Act 2016

Why the marks are here. Disability law is the point at which psychiatry stops being purely clinical and becomes a matter of enforceable rights, because mental illness is a specified disability in Indian law, and a person with mental illness is a person with a disability once that functional, barriers-based definition is met, and the protections, benefits and certification that follow all rest on a single statute. A candidate is asked for the salient features of that statute because the examiner wants four things placed correctly: what the Act is, where it came from, when it took effect, and what it replaced. Those anchors are the whole of a short-note answer, and they are also the facts most often muddled, because the Act is easy to confuse with the welfare law it superseded and easy to date to the wrong year.

The Act is best read at its origin, meaning its number, its long title, its commencement clause and the legislation it repealed, because every later provision inherits its character from that origin. Read this way it is not a welfare scheme with a few rights attached; it is a rights statute from its first line, written to bring an international convention into Indian law, and grasping why that is so is the difference between a pass-level answer and a good one. The recognised categories of disability, the certification machinery, the benefits and the guardianship reform each have their own detailed treatment elsewhere in this chapter; here the object is the Act as a whole, seen from its foundations.

49 of 2016	27 Dec 2016	19 Apr 2017	1995
ACT NUMBER	PRESIDENTIAL ASSENT	BROUGHT INTO FORCE	ACT IT REPEALED

15.1 The Act, its number and its short title

The Rights of Persons with Disabilities Act reached the statute book as Act No. **49 of 2016**, receiving Presidential **assent** on **27 December 2016**. An Indian statute carries two identifiers a candidate should keep apart: the short title, which names the Act and gives its year, and the official Act number, which fixes it in that year's sequence of central legislation. Both point to the same statute, and quoting either correctly signals that the answer rests on the primary Act rather than on a textbook paraphrase of it.

Section **1** is where the Act names itself and states when it will begin. It gives the short title, the Rights of Persons with Disabilities Act, **2016**, and then sets out the commencement rule. Its **long title**, the formal recital that opens the Act, announces its purpose in a single sentence, and here that sentence does real work: the purpose it declares is not the welfare of the handicapped but giving effect to an international rights convention. The long title is therefore not decoration; it is the interpretive key to everything that follows, and an examiner who asks for salient features is partly asking whether the long title has been read.

15.2 Commencement: assent is not coming into force

The most examinable trap in the whole topic hides in one clause. An Act does not become operative law on the day it is passed, nor even on the day it receives assent; it becomes operative on its **commencement**. The short-title-and-commencement section provides that the Act "shall come into force on such date as the Central Government may, by notification in the Official Gazette, appoint." The two modal verbs are doing different jobs and both must survive intact. The coming-into-force is mandatory, because the Act shall come into force, while the choice of the actual date is discretionary, left to the Central Government to appoint. The statute is certain that it will begin; it is deliberately silent about when.

The appointed date arrived by notification: the Act was brought into force on **19 April 2017** through **S.O. 1215(E)**. Between assent and that notification the Act existed on paper but bound no one, a period of dormancy that catches the candidate who dates the Act's operation to the year of its assent. This is not pedantry. Rights become claimable, and duties become enforceable, only from commencement, so any question about when an entitlement first arose, or from when a duty could be enforced, turns on the notified date and not on the date of assent.

TRAP **Assent is not commencement.** The Act received Presidential assent in one year but was brought into force by a separate Gazette notification on a later date. Date the operation of the Act, and the moment any right became claimable or any duty enforceable, to the notified commencement, never to the year of assent. Quoting the assent year as the year the Act "came into force" is an easy mark lost.

15.3 A statute built to give effect to a treaty

The single fact that explains the Act's whole character is that it was written to implement a treaty. Its long title declares it an Act to give effect to the United Nations Convention on the Rights of Persons with Disabilities, the **UNCRPD**, and the Act's preamble records that India ratified that Convention on **1 October 2007**. India follows a dualist tradition, in which ratifying an international convention expresses the State's commitment but does not by itself make the Convention enforceable domestic law. For its guarantees to be claimable in an Indian court, Parliament must legislate, and this Act is that implementing legislation. The interval of several years between ratification and enactment is precisely that dualist step being worked through.

This treaty parentage is why the Act reads as it does. Because it exists to give effect to the Convention, its provisions are construed purposively and in harmony with the Convention's principles rather than read down as narrow welfare measures. Where a later section is ambiguous, the long title and the Convention it serves supply the direction of travel, towards autonomy, inclusion and equal recognition before the law. A candidate who says only that the Act "protects the disabled" has missed the point that it exists to confer rights already recognised in international law, and it is that framing, not the vocabulary of protection, that the salient-features question is testing.

RULE **The Act is treaty-driven and therefore rights-based.** It exists to give effect to the disability Convention, and every provision is read in that light: disability is approached as a question of rights and of the barriers society raises, not as a matter of welfare or charity. State that character first and the salient features fall into place beneath it, because each one is an application of it.

IN INDIA

India ratified the disability Convention several years before it legislated, and turning that ratification into enforceable domestic law is exactly what this Act performs. The practical consequence for the Indian clinician is substantial. The rights of a person with mental illness to non-discrimination, to reasonable adjustment and to the entitlements that follow certification now rest on a rights-based statute carrying the broader UNCRPD social-and-rights model, rather than the narrower, impairment-and-threshold-based regime it replaced. That is a firmer footing from which to advocate for a patient, and it is why the Act, and not merely its schedule of benefits, is worth knowing at the bedside as well as in the examination.

15.4 From welfare to rights: the earlier Act repealed

The Act did not enter an empty field. It **repealed and replaced** the Persons with Disabilities (Equal Opportunities, Protection of Rights and Full Participation) Act, **1995**, the country's earlier dedicated disability legislation. The change of name signals a change of philosophy. The earlier Act framed disability as a matter of equal opportunity and protection, a narrower, impairment-and-threshold-based regime, while the new Act frames it as a matter of rights, in which the person is a **rights-holder** owed non-discrimination and the adjustments that make participation possible. That is the move from a medical-and-charity view of disability to a rights-based, socially grounded one, in which disability is understood to arise from the barriers a society erects and not from an impairment considered alone.

Two ideas carry that model into the text and both are worth naming, though their machinery is developed elsewhere. The first is reasonable accommodation, the duty to make the specific adjustments a person needs to exercise rights on an equal basis, a refusal of which is itself treated as discrimination. The second is equal recognition before the law, the principle that a person with disability retains legal standing and decision-making status rather than being displaced by a guardian as a matter of course. The full reform of guardianship that this principle drives is taken up in this chapter's account of benefits, reservations and guardianship under the Act; what matters at the level of salient features is that the Act's paradigm, and not simply its list of benefits, is what changed.

POINT OF CONTRAST	PERSONS WITH DISABILITIES ACT, 1995	RPWD ACT 2016
UNDERLYING MODEL	Welfare and protection; a medical-and-charity view	Rights-based; a socially grounded understanding of disability
LEGAL IMPETUS	Domestic enactment implementing a regional proclamation, not a binding UN treaty	Domestic enactment giving effect to a ratified United Nations convention
STANDING OF THE PERSON	Beneficiary of State provision	Rights-holder owed non-discrimination and accommodation
STATUS TODAY	Repealed and replaced	The disability law now in force

Gathered up, the salient character of the Act is best expressed as the principles it embodies:

- respect for inherent dignity, individual autonomy and the freedom to make one's own choices;
- non-discrimination and equality of opportunity;
- full and effective participation and inclusion in society;
- accessibility, so that the physical and informational environment does not itself disable; and
- reasonable accommodation as an enforceable entitlement rather than a favour.

The RPWD Act is India's rights-based enactment of the UNCRPD, Act No. **49 of 2016**, in force from **19 April 2017**, and the successor to the narrower, impairment-and-threshold-based law of **1995**.

15.5 The architecture of the Act

Asked for the salient features of the RPWD Act **2016**, the strongest answer also maps the Act's structure and knows where the detail of each limb sits. The Act recognises a defined and considerably broadened set of disabilities, bringing within its scope conditions that the earlier law did not, mental illness among them. It establishes a statutory machinery for the assessment and certification of disability. It confers rights and entitlements, including in education, in public employment and in access to benefits. It reforms guardianship along the Convention's lines and connects with the National Trust framework for certain conditions. It designates authorities and commissioners to monitor implementation and to hear grievances, and it creates offences and penalties for contravention and for discrimination. Each of these is a salient feature in its own right, and this chapter takes the recognised categories of disability, the certification route, the benefits and reservations, and the guardianship reform in turn.

What holds the structure together is the origin already set out. Every limb, meaning who is recognised, how they are certified, and what they are owed, is an expression of the same UNCRPD-aligned rights-based commitment that the long title announces, which the narrower, impairment-and-threshold-based 1995 Act did not carry. That is why reading the Act at its origin is not a preliminary to the salient features but the most salient feature of all: the character of the statute determines the reach of every provision built upon it, and an answer that leads with the benefits before the character has quietly inverted the Act.

PITFALL

The commonest real-world error is to keep working within the framework the Act repealed, citing the older statute or advising a patient and family as though disability were still a matter of welfare provision rather than enforceable right. A new certificate, entitlement or complaint must be founded on the current Act; action already taken under the 1995 Act is not thereby erased, since the Act's own savings provision deems it done under the corresponding RPWD provision. Reaching for the superseded legislation is the disability-side equivalent of quoting a criminal provision that a later code has already replaced, and it is marked as an error of currency, not merely of loose citation.

15.6 Why the psychiatrist is examined on it

Where it touches practice. The reason this Act belongs in a psychiatry syllabus at all is that, under it, mental illness is a specified disability, and a person with mental illness is a person with a disability once the Act's functional, barriers-based definition is met. That inclusion pulls psychiatry into the Act's machinery. The recognition of disabilities and the place of mental illness among them, the certification through which that recognition is proved, and the benefits, reservations and guardianship reform that recognition unlocks are each taken up in the discussions that follow, and each rests on the rights-based foundation set out here. Alongside the Mental Healthcare Act, which governs care, treatment and the rights of the person within mental-health services, this Act governs the civil and social standing of the same patient, and in practice the two are read together.

Knowing the Act at origin is therefore not an academic flourish. It tells the clinician which statute is live, on what footing a patient's entitlements rest, and why an assessment of disability is an act with legal consequence and not merely a clinical note. The candidate who can state the Act's number, its treaty purpose, its commencement and the law it replaced has the spine of the topic; everything the later provisions add is flesh on that spine.

GOOD TO REMEMBER

When you assess a patient whose illness limits their functioning over the long term, remember that your clinical opinion can be the gateway to statutory rights and not only to treatment. Because mental illness is recognised as a disability, the psychiatric assessment carries a civil consequence, and framing it as a right the patient holds, rather than a benefit you are kindly recommending, is both more accurate in law and more useful to the family sitting in front of you.

16 · Recognized disabilities and inclusion of mental illness

Why the marks are here. The Rights of Persons with Disabilities Act is the statute that decides who counts as disabled in Indian law, and psychiatry has a direct stake in the answer because mental illness is one of the conditions it recognises. Two questions recur, in the examination and at the bedside. The first is which impairments the Act actually lists, and where mental illness falls among them. The second is what the much-quoted forty-per-cent figure governs, because it is routinely misattached. Both are settled by reading the Act's own definitions and its Schedule

rather than by memory of what a disability certificate looks like, and a candidate who can separate the definition of disability from the benchmark threshold, and place mental illness correctly within the recognised list, has the whole of this topic.

The Act carried Indian disability law from a narrow, medically framed list to a broad, socially framed one aligned with the United Nations Convention on the Rights of Persons with Disabilities. For the clinician this is not academic. Recognition under this statute is the gateway through which a person with a severe and enduring mental illness reaches statutory protections and entitlements, and the psychiatrist is very often the first professional to see that a patient is eligible at all. Knowing exactly what the Act recognises, and on what terms, is therefore part of doing right by the patient, not only part of passing the paper.

40%	21	5
BENCHMARK THRESHOLD	SPECIFIED DISABILITIES	HEADS IN THE SCHEDULE

16.1 Two definitions the Act keeps apart

The single most examinable feature of this Act is that it defines disability twice, and the two definitions do different work. A **person with disability**, at section **2(s)**, means a person with a long-term physical, mental, intellectual or sensory impairment which, in interaction with **barriers**, hinders full and effective participation in society on an equal basis with others. Notice what this definition does not contain: any number. It is deliberately the barriers model, in which disability arises from the meeting of an impairment and a disabling environment, not from the impairment considered on its own. The qualifier long-term is doing quiet work here too, because a transient or short-lived impairment, however severe while it lasts, does not by itself answer the definition.

The definition has three elements a candidate should be able to lift apart cleanly:

- a long-term physical, mental, intellectual or sensory impairment;
- an interaction between that impairment and environmental or attitudinal barriers; and
- a resulting hindrance to full and effective participation in society equally with others.

Against this stands the **person with benchmark disability**, at section **2(r)**, and here a threshold appears. A person with benchmark disability means a person with not less than **40** per cent of a specified disability, where that disability has not been defined in measurable terms; and, where the disability has been defined in measurable terms, a person with disability as certified by the certifying authority. This category is narrower, and it is the one to which the Act pins its heavier positive entitlements, the reservations and the schemes, whose detail is dealt with separately in this chapter's account of benefits, reservations and guardianship under the Act.

Why two definitions, and not one, is the reasoning worth showing rather than reciting. The Act does two different jobs. It protects a broad class of people from discrimination and guarantees them accessibility and equal participation, and for that purpose it wants the widest, most inclusive definition, one with no arithmetic gate at all. Separately, it distributes scarce positive goods, reserved seats, reserved posts and targeted schemes, and for that it needs a narrower,

sharply defined qualifying group. The benchmark definition is that narrower gate. Reading the two definitions as one, or importing the threshold into the general definition, collapses a deliberate two-tier design and is exactly the error the next box warns against.

TRAP **The threshold belongs to benchmark disability, not to disability.** Candidates read the headline figure and conclude that a person must reach it to be a person with disability at all. The general definition carries no percentage; the threshold is a second, higher gate for benchmark-linked entitlements only. A patient can be a person with disability under the Act, protected from discrimination and owed accessibility, and still fall short of benchmark status.

AXIS	PERSON WITH DISABILITY	PERSON WITH BENCHMARK DISABILITY
Threshold in the definition	None; no percentage stated	Not less than the benchmark proportion of a specified disability
Underlying model	Barriers model: impairment in interaction with barriers	Quantified extent of a specified disability
What it establishes	Status, equality and the anti-discrimination protections	The qualifying gate for reservation and benchmark-linked schemes
Role of certification	Not defined by a percentage certificate	Certified by the certifying authority where the disability is measurable

16.2 The Schedule of specified disabilities

What actually counts as a specified disability is not left to clinical opinion; it is fixed by a list. A **specified disability** means, at section **2(zc)**, the disabilities enumerated in the Schedule to the Act. This closed-list technique is deliberate. Certifying authorities, courts and government departments need a fixed, common reference for who is inside the specified-disability class and who is not, and an itemised Schedule supplies a legal certainty that a purely descriptive definition cannot. The Schedule fixes specified disabilities for this certification and benchmark-linked machinery; it does not confine the broader status of **person with disability**, which section **2(s)** defines on its own terms, independently of Schedule membership. The technique has a cost worth naming, however: a genuinely impairing condition the Schedule does not list falls outside the specified-disability machinery until the Schedule is revised to admit it, which is why the recognised list is written to be amendable rather than closed for good. The Schedule also widened the recognised conditions, from the **seven** categories of the earlier disability legislation to **21** specified disabilities, and it is this expansion that first brought several psychiatric and neurodevelopmental conditions squarely within disability law.

The itemised conditions are organised under **five** heads:

- physical disability, covering locomotor disability, visual impairment, hearing impairment and speech and language disability;

- intellectual disability, within which specific learning disabilities and autism spectrum disorder sit;
- mental behaviour, which is mental illness;
- disability caused by chronic neurological conditions and by blood disorders; and
- multiple disabilities, including deaf-blindness.

Two placements are worth holding, because both are tested by asking a candidate to file a condition correctly. Intellectual disability and mental illness sit under different heads, a separation the Act insists on and returns to in its own definition of mental illness. And autism spectrum disorder, together with specific learning disability, sits under intellectual disability rather than under mental illness, which is where an unwary answer tends to place them. The head names are not loose labels. Each condition has a fixed address in the Schedule, and the marks reward the candidate who knows the address and not merely the neighbourhood.

RULE **Recognition is by inclusion in the Schedule, not by severity.** A condition is a specified disability under this Act because it is listed in the Schedule; the broader status of person with disability under section 2(s) is not confined to the Schedule. Severity, expressed later as the benchmark proportion, is a separate question that fixes the level of entitlement, not whether the condition is a specified disability at all. First establish that the condition is scheduled; only then ask how much of it the person carries.

16.3 Mental illness within the Schedule

Where psychiatry enters the statute. Mental illness appears in the Schedule under the mental-behaviour head, and the Schedule gives it its own definition. **Mental illness** means a substantial disorder of thinking, mood, perception, orientation or memory that grossly impairs judgement, behaviour, capacity to recognise reality or the ability to meet the ordinary demands of life. The drafting is broad and functional. It turns on gross impairment of everyday functioning rather than on any named diagnosis, and that is precisely what lets a range of severe and enduring psychiatric conditions qualify without the statute having to list each of them. The test the Act sets is disability of function, not the presence of a particular label, which sits comfortably with the wider principle in these notes that a diagnosis is not named to a patient as the currency of their care.

The definition then carries an express carve-out that examiners like to probe. It does not include **retardation**, described as a condition of arrested or incomplete development of mind characterised by subnormality of intelligence. The Act is not denying that intellectual disability is a disability; it recognises it fully, but under the separate intellectual-disability head, not within mental illness. The two are kept apart on purpose, because they call for different assessment and different supports, and folding them under one heading would blur both. For the examination the discrimination to keep ready is short: intellectual disability is recognised, but as intellectual disability, never as mental illness.

IN INDIA

Mental illness was not first recognised as a disability by this statute. The Persons with Disabilities Act of 1995 that it replaced already listed mental illness among the disabilities it recognised; what the present Act does is broaden and reorganise the disability framework, adding conditions and building the benchmark structure onto it, rather than granting mental illness its first statutory footing. The practical significance for the clinician is unchanged: a person with a severe and enduring psychiatric illness is, in principle, eligible for the same order of statutory protection and entitlement as a person with a physical disability. In day-to-day practice the psychiatrist is usually the professional who first recognises that a patient's illness has reached a disabling level, and who sets the patient on the pathway toward a disability certificate. Recognising eligibility early, and saying so plainly, is itself part of good care.

16.4 Recognition, certification and the definition that is not this one

Three boundaries decide whether an answer has understood this topic or has merely memorised the figure. The first is recognition against certification. Being listed in the Schedule makes mental illness a specified disability, not an automatically recognised individual disability; an individual with mental illness becomes a person with disability, and so gains the general rights the Act owes every person with disability, the protection from discrimination and the claim to accessibility and equal participation, only when the section **2(s)** elements are also met, the long-term impairment interacting with barriers to hinder participation, not by diagnosis or Schedule placement alone, and none of which turns on any percentage. What recognition does not by itself confer are the benchmark-linked entitlements. Those, the reservations and the schemes, follow only from a certificate that the person meets the benchmark threshold, and the machinery for assessing and certifying mental illness as a benchmark disability, the instrument used and the certifying authority, is taken up separately in this chapter's account of disability certification and the assessment of mental illness. For those benchmark entitlements recognition is the door and certification is the key, and this topic owns the door.

The second boundary is the benchmark against the benefit. The threshold is the entrance to the benchmark-linked reservations and schemes; separate general schemes open to persons with disability as such, resting on section **2(s)** status rather than on the benchmark proportion, also exist and are not gated by the threshold. The content of the benchmark-linked entitlements, who reserves what and the guardianship provisions that travel with them, belongs to this chapter's account of benefits, reservations and guardianship under the Act. This topic owns the definition of the gate, not the goods that lie beyond it, and a candidate who pours reservation proportions into a recognition answer has quietly answered a different question.

PITFALL

The Rights of Persons with Disabilities Act carries its own definition of mental illness, and it is not the definition used in the Mental Healthcare Act. The two provisions read similarly but sit in different statutes and do different work: one decides recognition as a disability for entitlements, the other governs care, admission and rights under mental-health law. Quoting the disability Schedule's definition when the question is about mental-health-care law, or the reverse, is a common and avoidable error. The Mental Healthcare Act's definition of mental illness is taught with that Act's definitional provisions, and each should be cited to its own statute.

The third boundary is the quietest, and it is the one clinicians actually trip on. Recognition, certification and benefit are three steps, not one, and a patient can be standing at any of them. A patient whose illness is plainly disabling, so that the section **2(s)** elements, the long-term impairment, its interaction with barriers and the resulting hindrance to participation, are met, is a person with disability, and that status already owes the general protections the Act gives every person with disability; what it does not by itself deliver are the benchmark-linked benefits, which wait until a certificate is issued and the entitlement is claimed. Keeping the three steps apart is what lets a clinician be honest with a family about what a diagnosis does, and does not, by itself deliver.

GOOD TO REMEMBER

When a patient with a severe, persistent mental illness asks about disability benefits, the answer comes in two parts. Recognition is not in doubt, because an illness this severe and persistent satisfies the section **2(s)** elements, and mental illness is in any event a specified disability under the Act. What the patient needs is certification, first of the specified disability and then, if the benchmark proportion is met, at the benchmark level, each a separate assessment carried out under its own machinery. The clinician's task is to flag eligibility early and route the patient into the certification pathway, rather than to promise a particular benefit that only certification and the benefits framework can actually confer.

Mental illness is a specified disability recognised in its own right and kept distinct from intellectual disability; the benchmark proportion governs benchmark disability and its entitlements, never the definition of a person with disability.

17 · Disability certification and assessment of mental illness (IDEAS)

Why the marks are here. For a person living with severe mental illness, a disability certificate is the document that turns a clinical fact into a quantified legal entitlement. It is the gateway to the specified-disability status and, once the benchmark is crossed, to the stronger concessions, welfare schemes and reservations the disability statutes pin to that number; the Act's general equality and non-discrimination protections attach to a person with disability independently of any certificate and do not wait on it. The examiner is rarely satisfied by the clinical picture alone. The marks sit on the exact statutory machinery - which provision empowers the guidelines, who is competent to certify, what procedure the applicant passes through - and on the one instrument

by which disability in mental illness is actually measured in this country. Get the chain and the computation right and the answer writes itself; blur a mandatory duty into a discretionary power, or read the percentage off the wrong number, and the mark is gone.

This topic is deliberately self-contained. It is about the DISABILITY certificate and nothing else. It is not the certificate of fitness to resume a job, not the assessment that sits behind a compensation or pension claim, and not the report a psychiatrist prepares for a court. Each of those is a separate certification with a different purpose and a different instrument, and the commonest way to lose the mark is to let one bleed into another. Mental illness is one of the specified disabilities the Act recognises; the recognition and definition of that category are treated separately in these notes, and what follows begins once mental illness is already inside the schedule and asks only how its disability is certified.

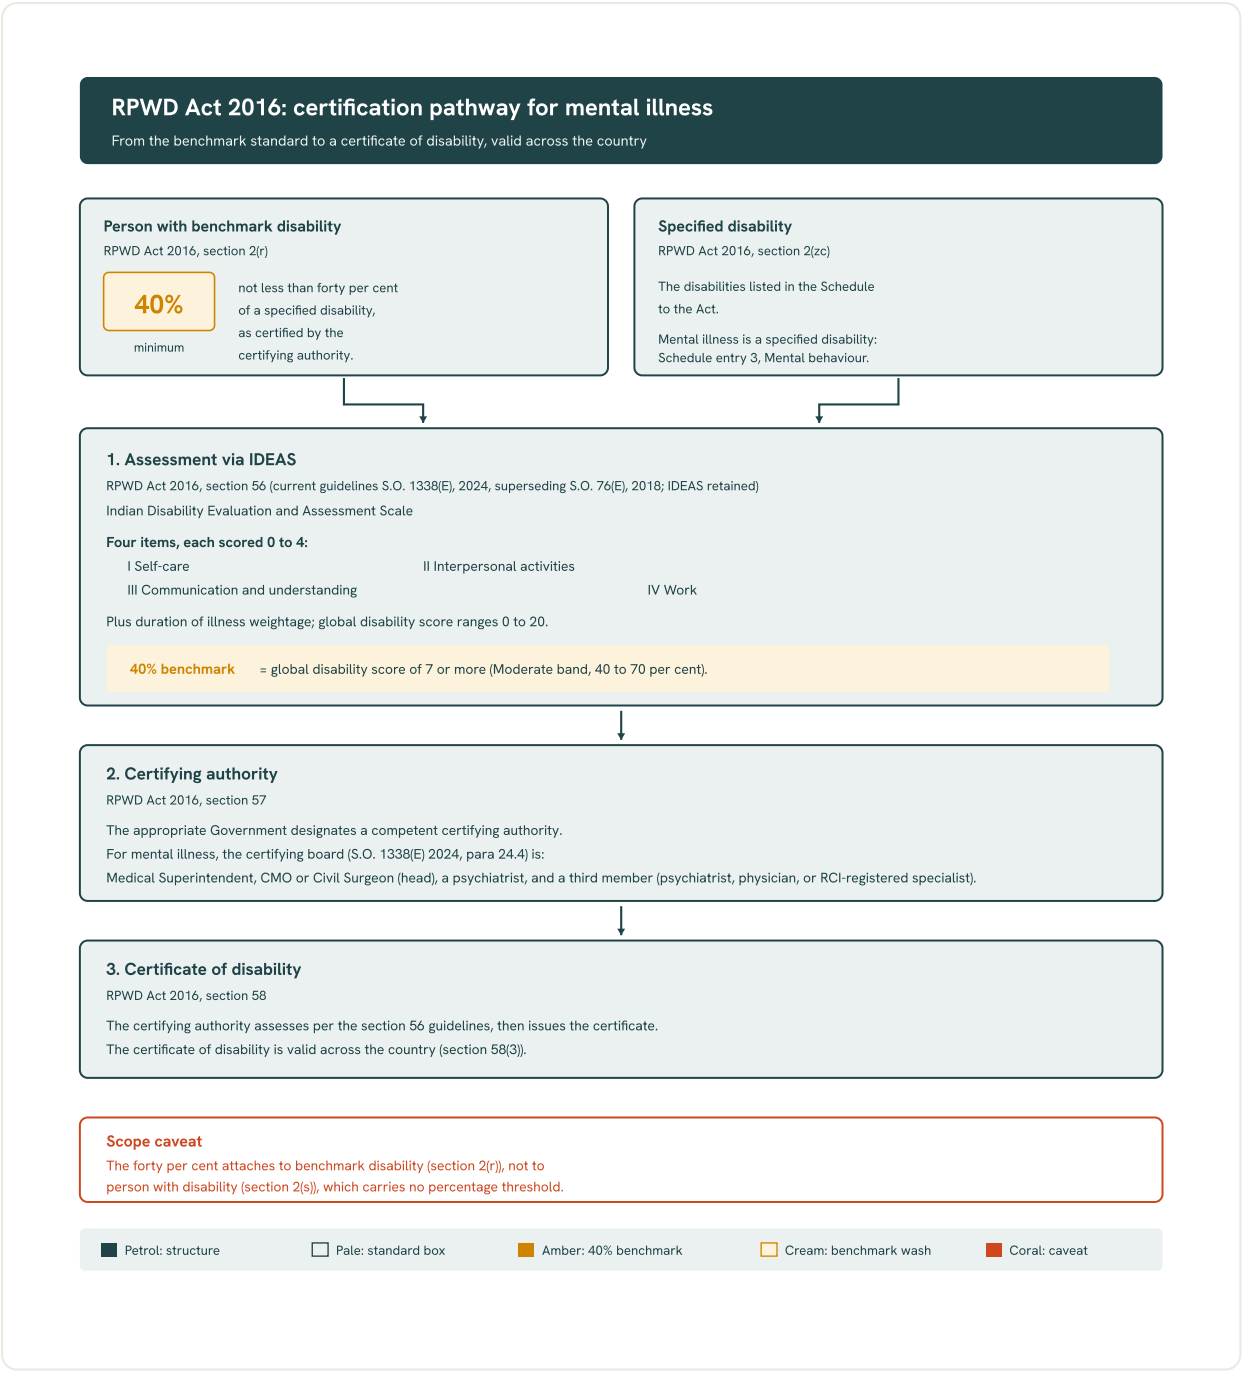

Fig 25.9. The RPWD Act 2016 route to a certificate of disability for mental illness: the benchmark standard of not less than forty per cent of a specified disability (section 2(r)) is measured with IDEAS under the section 56 guidelines, certified by the section 57 authority, and recorded on the section 58 certificate that is valid across the country.

17.1 The statutory chain: from the Act to a certificate

The Rights of Persons with Disabilities Act builds certification as a chain of three provisions, and each link carries an exact modal verb that must be reproduced. The first link is the enabling power at section **56**: the Central Government **shall** notify guidelines for the purpose of assessing the extent of a specified disability in a person. This is a mandatory duty, and it matters because nothing can be certified until those guidelines exist. They are the yardstick against which extent is measured, and a certificate issued against no notified guideline has no legal footing.

The second link, at section **57**, designates who may certify. The appropriate Government **shall** designate persons having the requisite qualifications and experience as **certifying authorities**,

competent to issue the certificate of disability, and shall also notify the jurisdiction within which, and the terms and conditions on which, they perform that function. Both duties are mandatory. A certificate issued by a person who has not been designated, or outside the notified jurisdiction, is not a valid certificate, which is why the identity of the certifying body is itself an examinable fact.

The third link, at section **58**, is the procedure the applicant actually passes through, and here the modal verbs switch deliberately. Any person with a specified disability **may** apply, in the manner prescribed by the Central Government, to a certifying authority having jurisdiction. The application is the citizen's option, never a compulsion. On receipt, the certifying authority **shall** assess the disability in accordance with the guidelines notified under the enabling power, and shall then either issue a certificate of disability in the prescribed form or inform the applicant in writing that he has no specified disability. The assessment is a mandatory duty and its two outcomes are the only two permitted: there is no lawful third option of leaving the application unanswered.

17.2 The assessment guidelines for mental illness

The guidelines the enabling power anticipates were notified by the Central Government in **2018** as gazette notification **S.O. 76(E)**, and they expressly superseded the older mental-illness guidelines of **2002**. For mental illness they lay down that assessment consists of a clinical assessment together with the IDEAS scale and, where it is relevant, an intelligence (IQ) assessment. Those 2018 guidelines also carried a discriminating rule that examiners used to return to: where both an IQ score and an IDEAS score were generated, the score indicating the more severe disability was taken, not an average and not whichever was measured first. That rule does not survive into the current 2024 notification, which instead directs that a person whose intellectual disability and mental-illness disability coexist is classified as having multiple disability and certified through the multiple-disability route, not by picking the worse of the two single-disability scores.

The same guidelines constitute the **certifying board** for mental illness. In outline the board is headed by a senior institutional officer, the Medical Superintendent, Chief Medical Officer or Civil Surgeon, or the equivalent officer a State notifies, and it includes a psychiatrist, who performs the clinical assessment, and a psychologist, who performs the IQ testing. This composition is worth holding, because it is the concrete answer to the section **57** question of who is competent to certify. The current notification is the 2024 **S.O. 1338(E)**, which superseded the 2018 **S.O. 76(E)**, and IDEAS is retained as the instrument, so the computation set out below is the tool a candidate must know. The 2018 notification is now historical. Its 2024 successor was not verbatim-verified for these notes, so the precise medical-board composition and the certificate-validity rules it sets are a declared gap: read the board as constituted per the current notification, but treat the exact 2024 designations, including that of the psychologist, as to be confirmed against the primary rather than settled here.

17.3 IDEAS: the instrument and its four domains

The Indian Disability Evaluation and Assessment Scale, **IDEAS**, is the instrument by which disability in mental illness is quantified for certification. It was developed by the Rehabilitation

Committee of the **Indian Psychiatric Society** and then adopted, with modifications, as the official tool. Its logic is important: it does not rate symptoms, it rates the disability that illness produces in everyday functioning. A florid mental state and a disabling one are not the same thing, and it is the second that the law compensates. IDEAS makes that judgement across **four** domains:

- **Self-care** - hygiene, grooming, bathing, toileting, dressing, eating and looking after one's own health.
- **Interpersonal activities (social relationships)** - initiating and maintaining interactions with others in a contextually and socially appropriate way.
- **Communication and understanding** - producing and comprehending spoken, written and non-verbal messages.
- **Work** - functioning in the domain of employment, housework or education.

Each domain is scored from **0 to 4**, the lowest step recording no disability in that area and the highest recording profound disability, a complete inability to perform. The rater's task is to convert clinical observation into these four graded judgements, which is why inter-rater consistency and a structured interview matter as much here as anywhere in the mental state examination.

MNEMONIC

Some Individuals Can Work

The four IDEAS domains in order: **S**elf-care, **I**nterpersonal activities, **C**ommunication and understanding, and **W**ork.

IN INDIA

Disability in mental illness is not certified on a free clinical impression but on a gazette-notified, home-grown instrument. IDEAS grew out of the Indian Psychiatric Society's own rehabilitation work and was then modified and notified by the Ministry of Social Justice and Empowerment, which is what makes it the official yardstick and also makes its items, scoring and computation government-open, free to reproduce with acknowledgement of the gazette notification. For an Indian candidate this is the answer that a Western disability scale would get wrong: the tool the law names is IDEAS.

17.4 Computing the score: total, duration weightage and global score

The four domain scores are added to give a total disability score, which therefore runs from **0 to 16**. IDEAS then does something distinctive that candidates routinely omit: it adds a weightage for the **duration of illness**. The reasoning is that chronicity compounds disability. The same symptom burden carried for a decade is more disabling than the same burden carried for a month, because it erodes the roles, skills, employment and social capital that do not quickly return once lost. The weightage is graded by how long the illness has run:

DURATION OF ILLNESS	WEIGHTAGE ADDED
under 2 years	**+1**
2 to 5 years	**+2**
6 to 10 years	**+3**
over 10 years	**+4**

The total disability score plus the duration weightage gives the **Global Disability Score**, which runs from **0 to 20**. It is this global figure, and not the raw four-item total, that is carried forward to the percentage. The distinction is small on the page and decisive in the exam and in the clinic, because the same four-domain profile can land in two different percentage bands depending only on how long the person has been ill.

4	0-16	0-20	40%
IDEAS DOMAINS	ITEM TOTAL	GLOBAL SCORE	BENCHMARK CUT-OFF

TRAP **Mapping the percentage from the four-item total.** The item total and the global score are different numbers, and only the global score carries the percentage band. Candidates score the four domains, read straight off to a percentage, and silently drop the duration-of-illness weightage. The weightage is added first, every time; the global disability score is what the percentage table responds to.

17.5 From global score to percentage and the benchmark

Where the number becomes an entitlement. The global disability score maps onto a severity band and a percentage of disability, and it is the percentage that the rest of the statutory world responds to. The banding is fixed by the notified guidelines, so it is read, not judged:

GLOBAL DISABILITY SCORE	SEVERITY	PERCENTAGE DISABILITY
0	No disability	**0%**
1 to 6	Mild	**below 40%**
7 to 13	Moderate	**40 to 70%**
14 to 19	Severe	**71 to 99%**
20	Profound	**100%**

The single figure to hold is the cut-off. The line that defines a **benchmark disability**, and that gates the Act's benchmark-linked reservations and schemes rather than every welfare measure, is **40%**, which is reached at the moderate band, that is at a global disability score of **7** or more. Below it, an applicant is still a person with disability who retains the Act's general rights, but does not cross the line to which the stronger, benchmark-linked concessions and reservations are pinned. The benchmark, in other words, is not merely a descriptor of severity; it is the switch that turns those entitlements on.

RULE **The percentage is a statutory computation, not a clinical impression.** The certificate rests on the IDEAS global disability score defined in the notified guidelines. A clinician's global sense that a patient is "severely ill" has no legal standing until it is expressed as that computed score and its percentage band, which is precisely why the instrument, the duration weightage and the banding must be applied as written rather than approximated.

PITFALL

Treating IDEAS as an intelligence test, or certifying from IDEAS alone when a coexisting intellectual disability is present. IDEAS is the instrument for mental illness; intellectual disability is assessed on IQ. Under the superseded 2018 guidelines a clinician who generated both scores took the more severe of the two; under the current 2024 notification, a person whose intellectual disability and mental-illness disability coexist is instead classified as having multiple disability and certified through the multiple-disability route. A clinician who still defaults to the old take-the-worse-score rule, or to IDEAS alone, is applying superseded guidance and under-certifies the very patient the safeguard was written for.

GOOD TO REMEMBER

Because the score is anchored to current functioning and to the duration of illness, it moves as the patient does. A certificate is a snapshot, not a life sentence. An applicant whose global score sits just under the benchmark today may cross it after a relapse and a longer illness course, and one certified during a severe episode may fall below the band after sustained recovery. Re-assessment when the clinical picture changes materially is part of using the instrument honestly, and it protects both the patient's genuine entitlements and the integrity of the certificate.

In mental illness the disability percentage is read off the IDEAS global disability score, and **40%** is the benchmark that opens the statutory entitlements reserved for benchmark disability.

17.6 The certificate: its reach, appeal and boundaries

Two features of the issued certificate are heavily tested. First, its reach: the certificate of disability **shall** be valid across the country. This pan-India validity is a deliberate reform of the unique-disability-identity era, replacing a patchwork of State-bound certificates with a single document a person can carry and use anywhere in the country. Second, its challengeability: the Act provides an appeal against the certifying authority's decision to an appellate authority the State designates, so a wrongly refused or wrongly graded applicant is not left without remedy. A candidate who names both the country-wide validity and the existence of an appeal shows the whole shape of the procedure, not just its front end.

Finally, the boundary that keeps this topic clean. The disability certificate is one of several psychiatric certifications and must not be confused with the others. It is not the certificate of fitness to resume a job, nor the assessment behind a workmen's compensation or disability-pension claim, nor the certificate or report a psychiatrist prepares for a court, which belongs to the Forensic ethics, consent and legal procedure notes. Each answers a different legal question

with a different instrument, and IDEAS and the benchmark threshold belong to this certification alone; they should not be borrowed to answer a fitness-to-work or a compensation question. Equally, the entitlements this certificate unlocks - the reservations, concessions, benefits and the guardianship framework of the disability statutes - are taken up in a separate section of these notes. Here the work ends at the certified percentage, which is exactly where the law means it to end and the next topic to begin.

18 · Benefits, reservations and guardianship under RPWD and National Trust Act

Why the marks are here. Guardianship is the point where disability law stops being about entitlements and starts being about a person's legal capacity to decide for themselves. Two Indian statutes govern it, and a candidate is expected to keep them apart. The Rights of Persons with Disabilities Act rebuilt guardianship around a rights-based, supported model; the National Trust Act built a separate, committee-appointed route for a defined group of developmental disabilities. Both create a machinery for a supporting or substitute decision-maker, both use the word guardianship, and by a quirk both place that machinery at the same-numbered section of their own Act, which is exactly why answers confuse them. The examiner is testing whether you know which statute reaches which person, and what kind of guardianship each actually confers.

The benefits-and-reservations half of this topic flows from the same rights-based logic. The Rights of Persons with Disabilities Act converts disability from a welfare category into a set of enforceable entitlements in education, employment and public schemes. The stronger of those entitlements attach to a person certified as having a benchmark disability, and how that certification is done, its instrument and its threshold, is taken up separately in this chapter's account of disability certification and is not reconstructed here. What follows is the guardianship framework in full, and the shape of the entitlements it exists to support.

> RPWD guardianship defaults to a limited, supported, decision-specific guardian appointed by a court or designated authority; the National Trust Act runs a separate, committee-appointed guardianship for its named developmental disabilities, and the two must never be merged.

Two	Limited	Committee	Support
PARALLEL STATUTES	THE RPWD DEFAULT	THE NATIONAL TRUST ROUTE	NOT SUBSTITUTION

18.1 From substituted to supported decision-making

The older Indian frameworks treated a person of unsound mind as globally incapable and installed a guardian to decide in their place. That is **substituted decision-making**, and its guardianship is **plenary guardianship**: a standing, all-purpose authority over the person and often their property. The Rights of Persons with Disabilities Act rejects this as the default. It begins from the presumption that capacity is retained, it offers support first, and it turns to a guardian only where a person, even after adequate and appropriate support, still cannot take legally binding decisions. This is **supported decision-making**, and the statute gives it a specific

legal form, **limited guardianship**, in which the guardian assists a decision rather than overriding it.

Why this shift matters clinically is easy to lose behind the vocabulary. A person's capacity to decide is rarely all-or-nothing: it is specific to a decision and it can change over time. A guardianship that removes decision-making wholesale, once and for all, mismatches that reality, disempowers the person, and invites abuse of the arrangement. A guardianship built to fit the decision that is actually in difficulty, and to expire when it is no longer needed, matches the clinical facts and keeps the person at the centre of their own life. That is the design intent the Act writes into law.

RULE **Guardianship under the RPWD Act is support, not substitution.** The default is a limited guardian who decides jointly with the person, for a defined decision and a defined period, in line with the person's own will; total support, subject to review, is the exception the court must specifically justify, never the starting point.

18.2 RPWD guardianship: the limited guardian

The reform is codified at section **14** of the Rights of Persons with Disabilities Act, headed Provision for guardianship. The trigger is deliberately narrow. Where a district court, or a **designated authority** notified by the State Government, finds that a person with disability who has already been given adequate and appropriate support is still unable to take legally binding decisions, that person may be provided the further support of a limited guardian to take legally binding decisions on their behalf, and to do so in consultation with the person. The modal verb matters: the court may provide this support, it is not bound to, and it enters only after ordinary support has already been tried and has not sufficed.

What limited means is defined inside the section, and it is the examinable core. Limited guardianship is a system of joint decision resting on mutual understanding and trust between the guardian and the person, and it carries these mandatory features:

- it shall be confined to a specific period, not granted as an open-ended status;
- it shall be confined to a specific decision or situation, not extended to the person's life at large; and
- it shall operate in accordance with the will of the person with disability, so the guardian gives effect to the person's own choice rather than displacing it.

The section also builds in an escape valve and a mandatory overlay. By its proviso, the court or designated authority may grant total support where the person genuinely requires it, or where limited guardianship would otherwise have to be granted repeatedly, subject to review, so the default is limited but total support, subject to review, remains available on the facts and under scrutiny. Separately, under **14(2)**, every guardian appointed for a person with disability under any other law is deemed to function as a limited guardian on and from commencement, an overlay that is not confined to appointments made before the Act and continues to catch guardians appointed under other laws afterward. Where the designated authority has appointed

the guardian, an appeal against that decision lies to an appellate authority notified by the State Government. Read together, these provisions make limited guardianship the rule, total support the justified exception, and the person's own will the standard the guardian is held to.

18.3 The National Trust Act route: the Local Level Committee

Running parallel to the RPWD scheme is the guardianship route under the National Trust for the Welfare of Persons with Autism, Cerebral Palsy, Mental Retardation and Multiple Disabilities Act, **1999**. This route is confined to the **four** conditions named in the Act's own title, and it is administered not by a court but by a **Local Level Committee** constituted under the Act. Its guardianship provision sits at section **14**, headed Appointment of guardianship, and its whole character is different from the RPWD instrument.

Two kinds of applicant may approach the committee. A parent of a person with disability, or a relative, may apply for the appointment of a person of their own choice to act as guardian. A **registered organisation** may also apply in the prescribed form, but here the Act adds a safeguard: no such application shall be entertained unless the consent of the person's existing guardian is also obtained. In deciding an application the committee shall consider two matters:

- whether the person with disability actually needs a guardian; and
- the purposes for which the guardianship is required.

The committee receives, processes and decides these applications and sends the particulars onward, and it also retains the power to remove a guardian it has appointed. The committee appoints the guardian for a defined group of developmental disabilities and orients the arrangement to the person's continuing care; but like every guardian appointed under a law other than the RPWD Act, that guardian is also deemed to function as a limited guardian under **14(2)** of the RPWD Act, so the committee supplies the appointing forum while the RPWD Act supplies the guardianship's limited, supported character. That is why families of children with autism or cerebral palsy are so often directed to the committee rather than to a court, and why the two statutes cover genuinely different ground even though the resulting guardian's authority is the same limited kind.

> **PITFALL**
>
> Do not route every guardianship request to the Local Level Committee. That door is open only for the conditions the National Trust Act names. A person whose disability is a mental illness lying outside those conditions falls under the Rights of Persons with Disabilities Act, before a court or a State-notified designated authority, and steering such a family to the wrong body costs them months they often cannot spare.

18.4 Two statutes, two guardianships, one confusion

Because the two Acts place guardianship at the same section number and use the same word for it, the commonest examination error is to describe one route with the features of the other. The way to protect the mark is to hold the axes apart and answer across all of them. The accompanying table sets out the discriminations an examiner tests.

AXIS	RPWD ACT, LIMITED GUARDIANSHIP	NATIONAL TRUST ACT ROUTE
Appointing body	District court, or a State-notified designated authority	Local Level Committee constituted under the Act
Default model	Limited, supported, joint decision-making	Committee-appointed for continuing care, but deemed a limited guardian under RPWD **14(2)**
Whom it reaches	Any person with disability under the Act's broad definition, not confined to the Schedule of specified disabilities	Only the developmental conditions the Act names
Who initiates	Follows a finding that support has not sufficed; done in consultation with the person	A parent, a relative, or a registered organisation applies
Scope and tenure	Confined to a specific decision and a specific period; total support only by justified exception	Appointment of a guardian for the person, removable by the committee
Underlying philosophy	Rights-based; capacity presumed; least restriction	Welfare and continuing care of a defined group

TRAP **Both provisions carry the same section number and the same label, yet they are different laws.** A candidate who memorises the guardianship section as one undivided fact loses the mark the instant the stem names a condition or an appointing body. The RPWD provision is limited and court-led and reaches any person with disability under the Act's broad definition, not merely the Schedule's specified disabilities; the National Trust provision is committee-led and confined to the conditions its Act names. Name the statute before you name the section, and the features fall into place.

GOOD TO REMEMBER

When a family asks you about guardianship, two questions settle the route before any form is filled: does the person's condition fall within the ones the National Trust Act names, and is a standing, total arrangement really needed, or would a limited guardian for a specific decision suffice? Reach for the least restrictive option that will work, and record why anything more was necessary, because both the statute and any later review will ask you exactly that.

18.5 Benefits and reservations, and where guardianship fits

Where the law bites in practice. The Rights of Persons with Disabilities Act does more than forbid discrimination; it creates positive entitlements. It reserves opportunities in higher education and in government employment for persons with benchmark disability, and it directs government to frame benefits and welfare schemes touching the education, health, livelihood and social security of persons with disability generally. The structural point the examiner wants is that the more substantial of these entitlements attach to a person recognised as having a **benchmark disability**, which is the qualifying category the Act uses to target its stronger

reservations and benefits. The precise proportions reserved, and the section numbers that carry them, belong to the salient-features treatment of this Act and are not asserted here.

How that recognition is assessed and certified, including the instrument used and the threshold that fixes a benchmark disability, is dealt with separately in this chapter's account of disability certification, and it should not be rebuilt in a guardianship answer. What matters for the present topic is the join between the two halves. A person may need a guardian precisely because a disability that affects decision-making is also what qualifies them for these entitlements, and a guardian, above all a limited guardian working in consultation with the person, is frequently the one who helps give those entitlements effect, from an educational place to a pension to enrolment in a scheme. The general civil-law machinery for managing the property and affairs of a person with mental illness sits outside both disability statutes and is taken up separately in these notes.

IN INDIA

Section **14(1)** gives the district court and any State-notified designated authority concurrent jurisdiction over a guardianship application, so a family may go to the district court whether or not an authority has been notified; in States that have not notified an authority, the district court remains the readily identifiable forum, so families meet very different waiting times from one State to another. The National Trust route, by contrast, is built to be reached locally through its committees, which is one reason it remains the practical first stop for parents of children with the developmental disabilities it covers, even though its guardianship is the less rights-forward of the two models. A psychiatrist who knows which door opens for which person, and can say so plainly to a family, saves them a great deal of avoidable delay.

In the examination this topic rewards the candidate who leads with the supported-decision reform, keeps the two guardianship routes cleanly apart, matches each modal duty to its correct statute, and treats benefits and reservations as entitlements gated by a certification taught elsewhere. Say those things in that order, name both Acts, and the answer reads as the work of someone who has understood the law rather than only memorised its headings.

Substance and narcotics law

19 · NDPS Act 1985 (salient provisions, classification of substances)

Why the classification carries the marks. The Narcotic Drugs and Psychotropic Substances Act, 1985, the NDPS Act, is India's principal criminal-control statute for drugs of abuse, and in an examination almost every mark it yields sits in two places: how the Act defines the substances it governs, and how it grades an offence by the quantity involved. This is not a pedantic point. How heavily an act is punished, and whether a route out of the criminal process toward treatment is open, follow substantially from which statutory class a substance occupies and in what amount it was held; but class and quantity alone do not decide whether the act is an offence at all, since the Act carries its own exception for medical or scientific dealing conducted within its rules, orders

and an applicable licence, permit or authorisation, and a treatment route further depends on addiction, voluntariness, a qualifying institution and the treatment being undergone. Get the class wrong and every conclusion built on top of it is wrong.

The discipline this topic really teaches is to read the Act as a lawyer reads it, from the primary text and by the Act's own definitions, rather than as a pharmacologist reads it. The statute does not ask what a molecule does in the brain; it asks where the law has placed that molecule. The clinical face of substance use, the dependence syndromes, withdrawal states and de-addiction pharmacology, sits outside this frame and is developed in the Substance use disorders notes; here the object is narrower and sharper, the law of classification itself.

Named	Listed	Notified	By statute
NARCOTIC DRUG, NAMED IN THE ACT AND EXTENDABLE BY NOTIFICATION	PSYCHOTROPIC SUBSTANCE, FIXED BY THE SCHEDULE	QUANTITY BANDS, SET BY THE CENTRAL GOVERNMENT	CLASS FOLLOWS THE LAW, NOT PHARMACOLOGY

19.1 Two classes, and a scheme graded by quantity

The Act builds its control in two central moves. It first names the things it governs, and for classification of controlled drugs the two principal statutory classes are narcotic drugs and psychotropic substances, distinct from the separate controls the Act carries elsewhere for precursor or controlled substances and for specified plants. It then criminalises the operations carried out around those two classes, the production, manufacture, possession, sale, purchase, transport and warehousing, together with the financing and harbouring that support them, subject to the Act's own exception for medical, scientific and otherwise licensed dealing conducted within its rules, orders and authorisations. On top of that prohibition it lays a graded scheme of punishment for many of its principal offences, in which the severity of the sentence tracks the quantity involved rather than the identity of the drug alone; several other offences under the Act carry offence-specific penalties independent of that quantity scheme. The examinable salient provisions are therefore not scattered across the Act; they gather at the front, in the definition clauses that fix the two classes, and in the quantity definitions that drive the sentence for the offences that turn on them.

Everything in the topic hangs off one organising idea, and it is worth stating before any single definition is opened: under this Act, what a substance is is a question answered by the statute, not by pharmacology. The Act works by naming and by listing, and a substance is controlled because the law has placed it in a controlled category, not because of what it does to the nervous system. This is the point a well-drilled candidate returns to whenever a definition looks counter-intuitive.

RULE **Classification under the NDPS Act is statutory, not pharmacological.** A substance falls within the Act because the Act's text names it or its Schedule lists it, not because of how the substance behaves in the body. Reason from the definition outward; reasoning inward from a drug's action is the single most reliable way to place a substance in the wrong class.

19.2 The narcotic drug: a means-and-includes definition

The Act's definition of a **narcotic drug** sits at section **2(xiv)**, and its drafting rewards close reading because the structure is itself examinable. The definition operates by **means and includes**: it first means a short, named set of substances, and then includes a further category on top. The named substances are:

- coca leaf;
- cannabis, in the sense the Act gives to hemp;
- opium; and
- poppy straw.

To that closed list the definition then adds its inclusion: it takes in all manufactured drugs as well. The means half is a fixed enumeration; the includes half opens the class to the category of manufactured drugs, which the Act defines separately on its own terms in another of its definition clauses. Read together, a narcotic drug is whichever of the named plant-derived substances the Act lists, together with the manufactured drugs the Act separately brings in, a closed list plus an inclusion, not an open description that a court is left to fill in.

Two features of that definition carry marks. First, the enumeration combines the closed list of four named source materials with a further inclusion for manufactured drugs, and a candidate should be able to recite the named heads rather than assume every manufactured drug is simply a derivative of one of them, since the Central Government can itself notify further substances into the manufactured-drug limb without touching the named list. Second, and more importantly, membership does not depend on pharmacology at all, and that is exactly where the classic error lives.

TRAP **Reading narcotic drug as a pharmacological category, and so excluding cannabis.** The everyday medical meaning of narcotic is a sedating opioid-type agent, and a candidate who imports that meaning reasons that cannabis, not being pharmacologically narcotic, must fall outside the definition. The statute says the opposite: cannabis is named in the enumeration and is a narcotic drug in law. Narcotic here is a legal label the text attaches, not a pharmacological description of the drug.

PITFALL

Trusting a secondary source for the exact words of the definition. The operative closing words of the narcotic-drug definition are all manufactured drugs. A widely used online case-law source reproduces the final word as manufactured goods, which is a transcription slip; the primary Gazette text of the Act reads drugs. When the precise word matters, and in a criminal statute it always does, verify the wording against the primary text of the Act rather than an aggregator, because one wrong noun quietly changes what the class contains.

19.3 The psychotropic substance: defined by the Schedule

The second class is built on a different mechanism, and the contrast between the two mechanisms is the heart of the topic. A **psychotropic substance** is defined at section **2(xxiii)**

not by naming particular drugs in the body of the Act, but by reference to a list. It means any substance, natural or synthetic, or any natural material, or any salt or preparation of such a substance or material, that is included in the list of psychotropic substances specified in the **Schedule** to the Act. Put plainly, a substance is psychotropic for the purposes of this Act if, and only if, it appears in that Schedule.

The definition is deliberately wide in one direction and narrow in another. It is wide in reach: it sweeps in natural and synthetic substances, raw natural materials, and any salt or preparation of them, so that a controlled substance cannot slip out of the class simply by being presented as a derivative or a formulation. It is narrow in gate: however broadly those words describe candidate substances, none of them is a psychotropic substance in law unless the Schedule actually lists it. The breadth describes what can be controlled; the Schedule decides what is.

This is the practical significance of a list-based definition. Because the controlled class is whatever the Schedule contains, the Act's reach over psychotropics can be extended by adding a substance to the Schedule, without reopening and rewriting the parent definition each time a new drug of abuse appears. The definition supplies the frame; the Schedule supplies the current contents. It is precisely this that separates the two classes in their primary mechanism: a narcotic drug's named list sits fixed in the Act's own enumeration, though its manufactured-drug limb can itself be widened by further Central Government notification, while a psychotropic substance is fixed entirely by the Schedule the Act carries with it.

19.4 Narcotic drug versus psychotropic substance

Because the two classes are defined by different machinery, a direct contrast is the examiner's favourite way into the topic. Setting them side by side on shared axes makes both the difference and its consequence easy to hold under pressure.

AXIS	NARCOTIC DRUG	PSYCHOTROPIC SUBSTANCE
WHERE THE CLASS IS FIXED	Enumerated in the body of the Act itself	Listed in the Schedule the Act carries
FORM OF THE DEFINITION	Means a named set and includes manufactured drugs, a closed list plus an inclusion	Means any substance, material, salt or preparation included in the Schedule, a gate by listing
WHAT IT TAKES IN	Coca leaf, cannabis, opium, poppy straw and manufactured drugs	Whatever the Schedule specifies, natural or synthetic, and their salts and preparations
RELATION TO PHARMACOLOGY	None: membership is by name, not by drug action	None: membership is by listing, not by drug action
HOW THE CLASS GROWS	By naming more in the Act itself, or by Central Government notification widening the manufactured-drug limb	By adding entries to the Schedule

MNEMONIC

Narcotics are Named; Psychotropics are Placed

Two words fix the whole contrast. A **Named** class: narcotic drugs are named in the Act's own enumeration. A **Placed** class: psychotropic substances are whatever has been placed in the Schedule. Hold which class is Named and which is Placed, and you can reconstruct both definitions and their key consequence, that a new psychotropic arrives by way of the Schedule while the named narcotic list sits in the Act itself. Qualify the mnemonic before relying on it: the manufactured-drug limb of the narcotic-drug definition can itself be widened by Central Government notification, so a narcotic drug is not confined only to what the Act names in so many words.

19.5 Classification by quantity: the graded scheme

The second axis of classification is amount, and it is what turns one prohibited act into a minor matter and another into a grave one. Once a substance is within either class, the Act does not punish every dealing with it identically: for many of its offences it grades the offence by the quantity involved, and it does so through two further definitions. A **commercial quantity**, at section **2(viia)**, is any quantity greater than the amount specified for that substance by the Central Government by notification in the Official Gazette. A **small quantity**, at section **2(xxiiia)**, is any quantity lesser than the amount similarly specified. Between the two lies an intermediate band, more than small but less than commercial, and the three bands attract punishment of ascending severity:

- a small quantity, drawing the lowest tier of punishment;
- an intermediate quantity, more than small but less than commercial, drawing the middle tier; and
- a commercial quantity, drawing the highest tier.

The structural point, and the one the exam rewards, is where the actual thresholds live. The Act does not fix the numbers. It defines the small and the commercial quantity by reference to amounts the Central Government specifies, substance by substance, in a Gazette notification, and the executive can revise those amounts without amending the Act. That is why an answer should state the scheme and its mechanism and should never attempt to recite thresholds from memory: the operative figures do not sit in the Act at all, they sit in delegated legislation, and they differ for every substance.

IN INDIA

The load-bearing feature of the Indian scheme is that the small-quantity and commercial-quantity thresholds are set by Central Government notification in the Official Gazette, not written into the Act. This keeps the classification responsive, because a threshold can be added or revised for a substance administratively, but it also means the operative numbers live outside the statute, in delegated legislation that a practitioner has to consult separately. The quantity seized, measured against the notified figure for that particular substance, is what fixes the band, and with the band the gravity of the charge.

The small-versus-commercial line does more than scale a sentence; for the individual relief provisions it also marks an outer limit, and that limit sits at small quantity itself, so an intermediate-quantity offence, more than small but below commercial, already falls outside that relief and not only a commercial-quantity offence does. The relief the Act extends to a qualifying addict is confined to the Act's consumption offence or to another offence involving a small quantity, not to offences sorted loosely into personal-consumption versus trafficking labels, and it does not reach an intermediate or commercial-quantity offence; a separate, systemic power the Act carries for the Government to establish treatment centres is not gated by offence-quantity at all. The full machinery of that individual relief, who qualifies, on what conditions, and how it sits against prosecution, is a distinct provision developed separately in these notes on the treatment and de-addiction side of the Act; what matters here is only that the quantity classification is part of the gate through which any such relief must pass.

GOOD TO REMEMBER

For the treating psychiatrist the quantity line is not an abstraction. Whether a dependent patient found with a substance faces the heaviest tier of the Act, or is instead eligible for the treatment-oriented route the Act reserves for consumption or small-quantity cases, turns on the class and the amount together. Knowing that the thresholds are notified rather than fixed in the Act, and that they differ by substance, is what keeps a clinician from either falsely reassuring a patient or overstating the jeopardy when the family asks what a seizure means.

Under the NDPS Act classification is a statutory question and not a pharmacological one: a narcotic drug is enumerated in the body of the Act, a psychotropic substance is whatever the Schedule lists, and for many of its offences the gravity is graded across small, intermediate and commercial quantities whose thresholds the Central Government fixes by notification rather than the Act.

20 · Treatment and de-addiction provisions, immunity for addicts under NDPS

Why the marks sit here. The Narcotic Drugs and Psychotropic Substances Act is remembered as a punitive statute, and for the trafficker it is exactly that. For the dependent user it also carries a reformative limb, and it is that limb the examiner probes, because answering well forces a candidate to separate three different powers that all point toward treatment yet operate at

different stages of the criminal process and under different modal verbs. One provision bars prosecution without requiring a finding of guilt. One lets a convicting court divert an offender into treatment instead of prison. One empowers the State to build the treatment system itself. Each is conditional, and reciting the headline without its conditions is how the mark is lost.

The idea that ties the limb together is that the law treats dependence as a condition to be treated rather than only an offence to be punished, but for the two individual routes below, that grace extends only to the consumption offence and to offences involving small quantity. The moment an offence involves more than small quantity, including the intermediate band below commercial, those two reformative routes fall away and the punitive machinery applies in full; the third, systemic provision carries no equivalent offence-quantity threshold, because it is a power to build the treatment system rather than an individual defence. Holding that boundary in mind keeps the two individual routes below in their correct scope, and the reader who wants the classification of quantities and substances that sets those bands will find it developed separately in these notes on the salient provisions of the Act. Here the object is narrower: the treatment, de-addiction and immunity provisions themselves.

Pre-conviction	Post-conviction	Systemic
IMMUNITY FOR THE ADDICT WHO VOLUNTEERS	RELEASE FOR TREATMENT IN PLACE OF SENTENCE	POWER TO ESTABLISH DE-ADDICTION CENTRES

20.1 Immunity from prosecution for the addict who volunteers

The reformative limb opens with a pre-conviction protection at Section **64A**, which grants **immunity from prosecution** to a dependent user who comes forward for treatment, without requiring a finding of guilt, and even while a prosecution against him is already pending. The provision reaches only a person who is an **addict**, which the Act defines as a person who is dependent on any narcotic drug or psychotropic substance. The immunity is not a pardon and it is not automatic; it is a conditional bar that attaches only when a defined set of facts is present, and the examiner rewards the candidate who can state those facts rather than the slogan.

The conditions must be read together, because the failure of any one of them dissolves the protection:

- the person is an addict within the meaning of the Act;
- he is charged with the offence of consumption of a narcotic drug or psychotropic substance, or with an offence involving only a **small quantity** of such substances, so that the bar does not extend to an offence involving more than small quantity, whatever that offence is labelled;
- he **voluntarily** seeks to undergo medical treatment for de-addiction;
- the treatment is at a hospital or institution **maintained or recognised** by the Government or a local authority; and
- he actually undergoes that treatment.

Where those conditions are satisfied the Act provides that he **shall not be liable to prosecution** for the consumption offence, or under any other section, for offences involving a small quantity.

The verb is mandatory. Once the addict has genuinely volunteered and undergone treatment at a qualifying institution, the bar operates as a matter of right, and the prosecuting agency has no discretion to insist that he nonetheless be tried. This is the design choice worth understanding: the State is prepared to forgo the prosecution of a consumption or small-quantity offence in exchange for the offender placing himself in treatment, because a treated dependent user serves the Act's purpose better than a punished one, while an offence involving more than small quantity, whatever it is called, is deliberately left outside; the boundary the Act draws is quantity, not the informal label of trafficking.

RULE **The bar on prosecution is mandatory; its withdrawal is discretionary.** The Act says the qualifying addict shall not be liable to prosecution, but the accompanying proviso says the immunity may be withdrawn if he does not undergo the complete treatment for de-addiction. The two halves of the same provision carry different modal verbs, and that split is the whole point. Protection is guaranteed to the one who completes; only the failure to complete reopens the door to prosecution, and even then the reopening is a discretion to be exercised, not an automatic consequence.

PITFALL

The provision is routinely recited as blanket immunity for a drug offence. It is nothing of the kind. It is confined to the consumption offence and to offences involving small quantity; a person whose offence involves more than small quantity, whatever it is labelled, gains nothing by volunteering for treatment. Equally, the immunity presupposes that the treatment was at a maintained or recognised institution and that it was actually undergone. Stating the immunity without its scope, or without those preconditions, is the commonest way the rule is misapplied at the bedside and in the exam alike.

20.2 Release for treatment in place of a sentence

Where the immunity route requires no finding of guilt, the second lever operates only after conviction. Section 39 gives the court a power of release on **probation** for treatment. When an addict is found guilty of the consumption offence, or of an offence relating to a small quantity, the court **may**, instead of sentencing him at once to any imprisonment, and **with his consent**, direct that he be released to undergo medical treatment for **de-toxification** or de-addiction. This is a judicial discretion, not an entitlement of the offender: the modal verb is permissive, and the offender's consent is a precondition, so the court may decline the course and the offender may refuse it.

The discretion is structured rather than open. The court exercises it having regard to the age, character, antecedents, or physical or mental condition of the offender, and only where it is of the opinion that it is expedient to do so. Release is then conditioned on the offender entering into a bond, with or without sureties, to appear and furnish a report on the result of his treatment within a period **not exceeding one year**, and meanwhile to abstain from any offence under the Act's substantive offences chapter. The treatment must be at a hospital or institution maintained or recognised by the Government; unlike the immunity provision, this route has no local-

authority alternative, so the two routes are close but not identical in the class of facility they accept.

The provision then looks past the treatment episode. After considering the report on the result of the treatment, the court **may** direct the release of the offender after due admonition, on his entering into a further bond to be of good behaviour and to abstain from the substantive offences for a period **not exceeding three years**. The structure is therefore a supervised pathway that runs from conviction, through a treatment episode reported back to the court, to a probationary discharge on good behaviour, the whole of it turning on the offender's consent and on the treatment report he furnishes to the court, rather than on incarceration.

> **GOOD TO REMEMBER**
>
> When an addict has been diverted under this power, the psychiatrist's report on the result of treatment is the very document the court acts on. Recording that the patient presented, engaged with treatment, and the outcome of that engagement is what the report conveys to the court; the further, good-behaviour release turns on that report being furnished and considered, not on a defined course being completed, though a report showing non-engagement leaves the court free to fall back on sentence. The clinical content of that de-addiction course, the pharmacology of detoxification and relapse prevention, belongs to the Substance use disorders notes; what the statute needs from the clinician is an accurate account of engagement and outcome.

20.3 Building the treatment system: establishing de-addiction centres

The first two provisions presuppose that a qualifying institution exists to treat the addict; the third supplies the power to create one. Section **71** empowers the Government to build the de-addiction infrastructure. In its current, amended form it provides that the Government **may** establish, recognise or approve as many centres as it thinks fit, and it names the purposes those centres serve:

- identification, treatment and management of addicts;
- education, after-care and rehabilitation;
- **social re-integration** of addicts; and
- supply of narcotic drugs and psychotropic substances to addicts registered with the Government, and to others where such supply is a **medical necessity**.

The verb is again permissive. This is an enabling power the Government may exercise, not a duty to place a centre in every district, and a second limb allows the Government to make rules for the establishment, maintenance, management and superintendence of such centres and for the supply of the controlled substances from them. It is that controlled-supply purpose that distinguishes the provision from an ordinary health-service enabling clause: the section enables the concerned Government, subject to such conditions and in such manner as may be prescribed, to supply narcotic drugs and psychotropic substances to registered addicts and where supply is a genuine medical necessity. It is not itself a licence, and it does not by itself legalise a centre's or clinician's own supply; compliance with the Act, its rules, orders and any applicable authorisation

remains necessary before supervised substitution or maintenance services can rest on firm ground.

One point of currency is examinable here. Older textbooks quote the original wording, under which the Government might, in its discretion, establish such centres; the current text broadened that to establish, recognise or approve, and expressly added management and social re-integration to the list of purposes. The modern provision should be cited in its amended form, and an answer that reproduces the older discretion-only wording as though it were the current law dates itself.

IN INDIA

The reformative limb only works if a qualifying institution is actually within reach, which is why this provision matters in Indian practice as much as the immunity itself. The two individual routes each require treatment at a qualifying institution, though the qualifying class differs slightly: the immunity route accepts recognition by the Government or a local authority, while the release-for-treatment route requires recognition by the Government alone. The crucial practical question for a clinician asked to support a claim of protection under either route is whether the treating facility carries the recognition that route requires. A course completed at an unrecognised facility does not answer the statute, however good the care. The centres provision is different in kind: it is the power by which Government establishes, recognises or approves such centres and, subject to prescribed conditions, supplies controlled substances through them; it is not itself an individual eligibility condition, and it does not licence a centre's or clinician's own supply. The clinical work delivered inside such a centre lies beyond the statute.

20.4 Reading the provisions correctly: stage, consent and the modal verbs

Where candidates come unstuck. The three provisions are easy to blur into a single sentence to the effect that the Act lets addicts get treatment instead of punishment, and that blur costs marks because it hides the very distinctions being tested. The two treatment routes for an individual differ in the stage at which they operate, in whose power they are, and in what triggers them; the third provision is not a route for an individual at all but a systemic enabling power. Setting the two individual routes side by side on shared axes makes the differences easy to hold under pressure.

AXIS	IMMUNITY ROUTE (PRE-CONVICTION)	RELEASE-FOR-TREATMENT ROUTE (POST-CONVICTION)
STAGE	Without a finding of guilt; can operate even while prosecution is pending	After a finding of guilt, in place of sentencing
WHOSE POWER	Operates for the addict as of right once the conditions are met	A discretion of the convicting court
STATUTORY VERB	Shall not be liable to prosecution, a mandatory bar	The court may direct release, a permissive power
CONSENT	Implicit in the act of volunteering for treatment	Express consent of the offender is required
ONGOING CONDITION	May be withdrawn if the complete treatment is not undergone	Bond to furnish a treatment report, then a good-behaviour bond
ELIGIBLE OFFENCES	Consumption and small-quantity offences only	Consumption and small-quantity offences only

The shared floor of the two routes is as instructive as their differences. Both are confined to the consumption and small-quantity end of the Act, both require the offender's willing participation, and both are conditioned on treatment at a recognised institution, though only the immunity route's proviso turns on that treatment being completed; the release-for-treatment route turns instead on a report on the treatment being furnished and considered. What separates them is only the moment at which the law intervenes and the identity of the actor whose choice controls the outcome: before any finding of guilt the choice and the benefit belong to the addict, while after conviction the choice belongs to the court and is exercised only with the offender's agreement.

TRAP **Collapsing the pre-conviction immunity and the post-conviction release into one provision.** They share a purpose and a scope, but one is a mandatory bar that prevents prosecution without requiring a finding of guilt, and can operate even while prosecution is pending, belonging to the addict once he qualifies, while the other is a permissive judicial power exercised only after conviction and only with the offender's consent. A candidate who describes the immunity as the court's discretion, or the release as an automatic entitlement of any addict, has swapped their essential features and forfeits the discrimination the question is testing.

The immunity provision bars prosecution of the addict who voluntarily undergoes complete de-addiction at an institution maintained or recognised by the Government or a local authority, for the consumption offence or an offence involving small quantity; the bar is mandatory, and only his failure to complete treatment may reopen it, and then at the authority's discretion.

Criminal responsibility and forensic assessment

21 · McNaughton rules and Section 84 IPC (insanity defence)

Where the criminal law admits a mind can be too disordered to blame. The insanity defence is the point at which the criminal law concedes that a person may perform the forbidden act and still not be a criminal, because the mind that produced the act was too disordered to carry responsibility for it. It is the oldest of the forensic questions and the most heavily examined, and in an Indian paper it now carries a second, sharper demand: the candidate must show that the substantive law has changed. The unsound-mind exception has moved out of the Indian Penal Code and into the Bharatiya Nyaya Sanhita (BNS), and the rule that fixes who must prove what has moved out of the old evidence law and into the Bharatiya Sakshya Adhiniyam (BSA). The two moves answer different questions: which insanity provision governs turns on the date of the alleged offence, while which evidence law governs turns separately on whether the proceeding was already pending when the Adhiniyam came into force. An answer that recites the old penal-code section as the live law forfeits the currency mark even when the doctrine it states is otherwise sound.

Behind the statute stands one common-law inheritance. Both the superseded Indian provision and the one that replaced it are codifications of the **McNaughton rules**, the answers the English judges gave when asked when madness should excuse. Everything examinable here is an unpacking of that lineage: what the rules require, how the Indian code recast them, what changed on the appointed date and what deliberately did not, and where the law places the burden of proof. It is also the criminal-responsibility face of a wider idea running through the chapter, that capacity is decision-specific and time-specific, one question seen from many legal angles, and its synthesis is drawn together elsewhere. The concern here is the one capacity a court asks about after a crime: whether the accused, at the instant of the act, could know what the law required him to know.

22	84	108	1 July 2024
CURRENT EXCEPTION, BHARATIYA NYAYA SANHITA	HISTORICAL EXCEPTION, PENAL CODE	BURDEN OF PROOF, SAKSHYA ADHINIYAM	RECODIFIED LAW IN FORCE

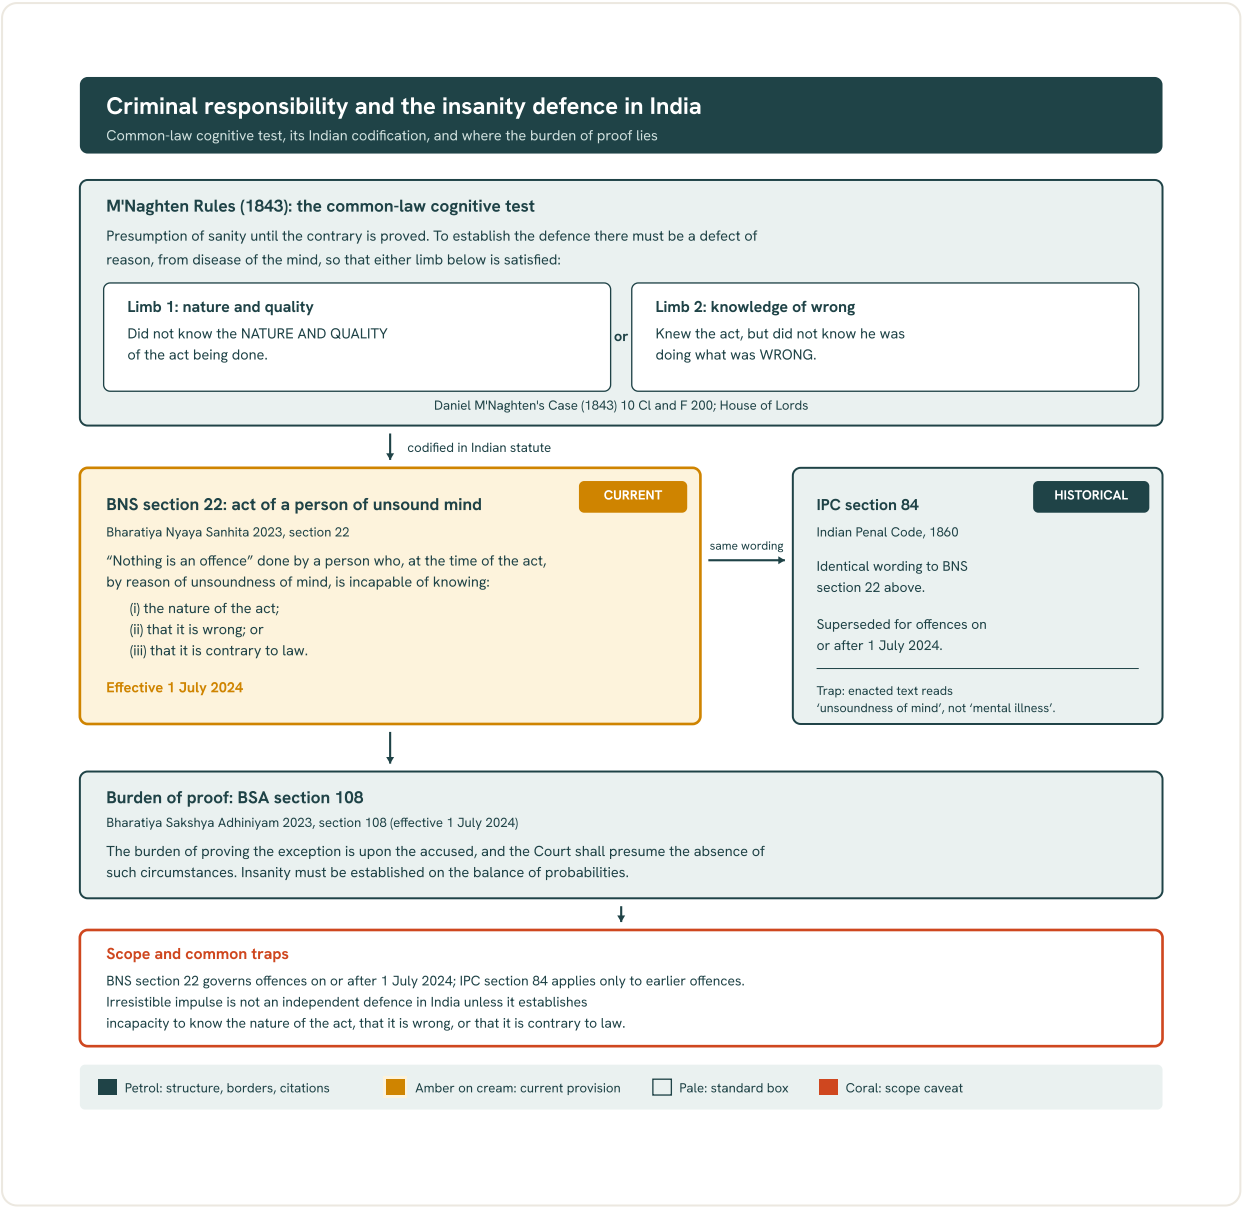

Fig 25.10. Criminal responsibility for the mentally ill offender in India: the two M'Naghten cognitive limbs are codified in BNS section 22 (current, effective 1 July 2024), which reproduces verbatim the wording of the now-historical IPC section 84, while BSA section 108 places the burden of proving the exception on the accused, to the balance of probabilities.

21.1 The McNaughton rules: the common-law origin

The rules take their name from Daniel M'Naghten, tried for a killing carried out under a paranoid delusion and acquitted on the ground of insanity. The acquittal caused enough public disquiet that the House of Lords put questions to the judges, and their replies, offered as an advisory statement of the law rather than as a decision in the case, became the formulation the common-law world has relied on ever since. The defendant's surname is spelled several ways across the reports, M'Naghten and McNaughton among them, and nothing of substance turns on the spelling; what matters is the test the judges set out in **1843**.

Two elements frame the rules before the test proper. The first is a starting position: every person is presumed sane, and to displace that **presumption of sanity** the defence must be clearly proved. The second is a threshold condition: the accused must have been labouring under a **defect of reason** arising from a **disease of the mind**. Ordinary confusion, ignorance or strong

emotion will not do; only a genuine failure of reasoning grounded in mental disease opens the door to the test.

The test itself has two limbs, set in the alternative so that either alone will suffice. At the time of the act, and as a consequence of the defect of reason, the accused either did not know the nature and quality of the act he was doing, or, if he did know that, he did not know that what he was doing was wrong. The whole enquiry is pitched at knowledge, which is why the rules are described as a purely **cognitive test**: they ask what the accused was able to know, not whether he could govern himself. A man who knew precisely what he was doing and knew it to be wrong, yet was driven to it by an urge he could not master, falls outside the rules as framed. That deliberate narrowness is the origin of every later objection to the test, and the alternative formulations devised in answer to it are examined elsewhere in this chapter; the Indian codes, as the following sections show, retained the McNaughton frame rather than discarding it.

21.2 Codification in India: the historical penal-code exception

When the general criminal law of the country was first codified, the McNaughton rules were written into the Penal Code as its general exception for the person of unsound mind, at section **84**. That provision was the Indian insanity defence for well over a century, and it governed the question until the recent recodification. It rendered the common-law test into a single sentence: nothing is an offence which is done by a person who, at the time of doing it, by reason of unsoundness of mind, is incapable of knowing the nature of the act, or that he is doing what is either wrong or contrary to law.

Two features of that recasting repay attention, because both are examined. The drafters kept the legal phrase **unsoundness of mind** rather than any clinical term, holding the exception broad and legal rather than pinned to a diagnosis. And where the English rules spoke only of not knowing the act was wrong, the code opened that single limb into two, wrong or contrary to law, recognising a wider set of cognitive failures than the common-law wording named. Both points are taken up below.

The status of this section is the first thing to state and the easiest to get wrong. It applied before the general criminal law was recodified and it continues to govern offences committed while it was the law in force; it is not the current provision. Naming it as the source of the Indian test is correct; naming it as the live exception for a present-day offence is precisely the currency error this topic exists to catch.

21.3 The current provision, and the date that switched it on

The recodification replaced the Penal Code, and the insanity exception moved across to BNS Section **22**. The Sanhita states the rule in words identical to the historical section, down to the phrase unsoundness of mind and the same set of cognitive incapacities: it reproduced the old exception verbatim and did not modernise it. The doctrine did not change; only the statute book that carries it did.

The examinable pivot is the date. The Sanhita did not fix its own commencement; it left the appointed date to the Central Government, to be notified in the Official Gazette, and the date so

appointed was **1 July 2024**. From that date the Sanhita's exception is the governing substantive provision, and the historical penal-code section recedes to the offences committed before it. The two never compete: which applies is settled entirely by when the alleged act was done, so an opinion that has not first fixed that date may be reasoning under a statute that does not apply to the case.

Note the grammatical force of the provision, because it is not a discretion. It declares that nothing is an offence in the stated circumstances; where the exception is made out the act is simply not a crime, not an offence the court may excuse as a matter of leniency. That declaratory character is what makes the exception a true answer to liability rather than a plea in mitigation.

AXIS	HISTORICAL PROVISION (PENAL CODE)	CURRENT PROVISION (BHARATIYA NYAYA SANHITA)
STATUS	The pre-recodification insanity exception, now superseded	The substantive insanity exception in force
OFFENCES IT GOVERNS	Offences committed before the appointed date	Offences committed on or after the appointed date
WORDING OF THE TEST	Unsoundness of mind; incapable of knowing the nature of the act, or that it is wrong, or that it is contrary to law	Reproduced word for word, without amendment
PAIRED BURDEN STATUTE	Not fixed by this axis. The evidence statute, and so the burden provision, follows the pendency of the proceeding when the Adhiniyam commenced, not the date of the offence: a proceeding already pending continues under the former evidence law, and a proceeding not then pending takes the Bharatiya Sakshya Adhiniyam.	

21.4 Reading the exception: the incapacities, and legal versus medical insanity

The substance of the exception lies in what the accused must have been incapable of knowing, and there are three such incapacities. It is enough that, by reason of unsoundness of mind at the time of the act, the accused was incapable of any one of them:

- that he could not know the nature of the act, its physical character and immediate consequences;
- that he could not know the act was wrong, in the moral sense the law attaches to wrongdoing; or
- that he could not know the act was contrary to law, that it was forbidden by the legal order.

The relation between the second and the third is the fine point examiners reach for. The common-law rules spoke only of not knowing the act was wrong; the Indian code split that into wrongfulness and unlawfulness, so incapacity as to either suffices. The effect is an exception a little wider than the single English word would allow, and a candidate who folds the two back together has quietly narrowed the section its drafters opened.

MNEMONIC

Could not know: the Nature, the Wrong, the Law

The three cognitive incapacities the exception recognises: at the time of the act, and by reason of unsoundness of mind, the accused was incapable of knowing the **N**ature of the act, or that it was **W**rong, or that it was contrary to **L**aw. Any one of the three suffices, and every one of them is about knowing, never about being able to resist.

Legal insanity is the name the courts give to what the section demands, and it is not the same thing as a psychiatric diagnosis. A person may carry a severe mental illness and remain criminally responsible if, at the moment of the act, that illness did not deprive him of the capacity to know the nature of the act, or its wrongfulness, or its unlawfulness. What exempts is not the presence of disease but the specific cognitive incapacity the section describes, assessed at the instant of the act. This distinction between legal insanity and mere medical illness is the most productive discrimination in the topic, and it is why a bare diagnosis, however grave, never on its own makes out the defence.

RULE **Legal insanity, not medical illness, decides the defence, and the test is wholly cognitive.** The exception exempts only the accused who, by reason of unsoundness of mind at the time of the act, was incapable of knowing the nature of the act, or that it was wrong, or that it was contrary to law. It asks nothing about whether he could control his conduct, and it is not satisfied by the presence of a diagnosis, however severe.

AXIS	THE MCNAUGHTON RULES (ENGLISH COMMON LAW)	THE INDIAN CODIFIED TEST
THRESHOLD CONDITION	A defect of reason from disease of the mind	Unsoundness of mind
FIRST LIMB	Did not know the nature and quality of the act	Incapable of knowing the nature of the act
WRONGFULNESS LIMB	Did not know the act was wrong	Incapable of knowing it was wrong, or that it was contrary to law
CHARACTER OF THE TEST	Cognitive; about knowing, not controlling	Cognitive; no volitional limb was added

TRAP **Importing an irresistible-impulse limb the Indian law does not contain.** The exception exempts only the accused who could not know the nature of his act, or its wrongfulness, or its unlawfulness; it says nothing about an inability to resist a known and wrongful impulse. Candidates read a volitional test into the section, or treat any grave diagnosis as automatically exculpatory, and both misstate what is a narrow cognitive rule.

IN INDIA

Indian courts decide the defence on legal insanity, not medical insanity, and they give real weight to the conduct surrounding the act. Evidence of planning, of concealment or of flight after the act tends to show that the accused knew the nature and the wrongfulness of what he did; it may weigh against the exception, but does not by itself defeat it, however unwell he may be. The corollary for the psychiatrist is that the opinion must speak to the accused's capacity to know at the moment of the act, reconstructed from the whole record, and not merely to the diagnosis he carried before or after it.

21.5 Who must prove it: the burden and the presumption

Establishing the defence is not the same as raising it, and the difference is fixed by the law of evidence. The **burden of proof** for the insanity exception, as for every general exception, sits at section **108** of the Bharatiya Sakshya Adhiniyam. Its rule is that when a person is accused of an offence, the burden of proving the existence of circumstances that bring the case within a general exception is upon him, and the court shall presume the absence of such circumstances. The accused therefore does not merely raise the possibility of insanity; he must prove it, and the court begins from the presumption that he was sane.

The standard he must meet is lighter than the one the prosecution carries. The prosecution must still prove the offence beyond reasonable doubt, and that general burden is not displaced; but the accused establishes the exception on the balance of probabilities, the civil standard, which is why an insanity defence can succeed on evidence that would fall short of a conviction. Holding the two standards apart is the examinable core, and the presumption of sanity is what the accused must overcome to reach the exception.

This mirrors the common-law rules, which already required insanity to be clearly proved from a presumption of sanity; the modern evidence statute reproduces the burden rule of the law it replaced, so the allocation did not change with recodification, only the statute that houses it. A candidate must state without hedging that the burden lies on the accused, that the court shall presume its absence, and that the standard resting on him is the balance of probabilities.

For an act done on or after the appointed date the insanity exception is the Bharatiya Nyaya Sanhita provision, which reproduces the old penal-code section word for word; the test is purely cognitive, and the accused must establish it on the balance of probabilities while the court presumes his sanity.

21.6 The psychiatric assessment, and the questions that are not this one

What the psychiatrist decides, and what only the court decides. Because the exception turns on a mental state at one past moment, the assessment is retrospective and functional. The task is to reconstruct, from contemporaneous records, the accounts of the act, the person's own narrative and the known course of any disorder, whether at the time of the act the accused was capable of knowing the nature of the act and its wrongfulness or unlawfulness. The psychiatrist supplies a medical opinion on that capacity; the conclusion of law, that the accused was legally

insane and so not criminally responsible, belongs to the court alone, which reaches it on the whole case and never on the diagnosis alone.

Several neighbouring questions are constantly confused with this one, and each is answered by its own law rather than by the insanity exception:

- whether the accused can be tried at all turns on his mental state at the time of the trial, not the time of the act, so a person may be fit to be tried for an act committed while insane, or unfit to be tried although he was fully responsible when he acted; that trial-time capacity is taken up separately in this chapter;
- whether an abnormality that fell short of the exception can still lower the grade of a killing, and whether an act done without conscious control is answerable at all, are the questions of diminished responsibility and of automatism, treated in their own place in this chapter and not by restating this exception;
- the criminal responsibility of a child, exempted by reason of age rather than of unsoundness of mind, belongs to the Child psychiatry: assessment, treatment, services and protection notes, and not to the insanity defence at all.

The manner in which the opinion is finally put before the court, the form of the report, the certification of the expert to give evidence and the conduct of the testimony, is not part of this substantive law and belongs to the Forensic ethics, consent and legal procedure notes.

GOOD TO REMEMBER

Before writing a line of opinion, fix the date of the alleged act, because that date decides which insanity provision applies to the case; the burden statute is decided separately, by whether the proceeding was already pending when the Bharatiya Sakshya Adhiniyam commenced. Then anchor the opinion to the accused's capacity to know at the moment of the act rather than to the diagnosis he happens to carry, and say plainly where the record cannot support a firm view. The legal label is the court's to attach; your work is the mental state and its bearing on knowing.

PITFALL

Citing the superseded penal-code section as the live insanity provision in a real medico-legal report. For an offence on or after the appointed date the governing exception is the Bharatiya Nyaya Sanhita provision, and a report resting on the old section invites the other side to point out that it relied on a law no longer in force. The wording is identical, so the doctrine survives the slip, but the citation does not, and a discredited citation weakens the witness. Fix the date first, then cite the statute that the date makes applicable.

22 · Other tests of criminal responsibility (Durham, irresistible impulse, ALI)

The insanity defence is not one rule but a family of them. The M'Naghten test that governs the Indian courtroom asks a single, cognitive question: did the accused, by reason of unsoundness of mind, fail to know the nature of his act, that it was wrong, or that it was contrary to law? That narrowness is deliberate and it is taught in full under the McNaughton rules elsewhere in this

chapter, but it leaves two familiar figures outside the door. One is the defendant who knew perfectly well that his act was wrong and yet, driven by illness, could not stop himself. The other is the defendant whose crime seems to pour directly out of a disease process. Anglo-American courts spent a long stretch of the modern era building tests to catch those cases, and the three that recur in every forensic viva are the volitional supplement known as irresistible impulse, the causal Durham or product test, and the two-limbed test of the American Law Institute. The examiner wants three things: the exact formulation of each, where each sits against the M'Naghten baseline, and the point that decides most answers, which is that none of them is Indian law.

Understanding why these tests were built, and why they were then narrowed or abandoned, is worth more than memorising their words. Each was an attempt to fix a perceived defect in the cognitive test, each overcorrected in a different direction, and the arc of American doctrine over the last several decades is essentially the story of the courts finding the right width. India watched that experiment and kept its cognitive frame. A candidate who can narrate that arc, and place the Indian position at the end of it, has the whole topic.

22.1 The cognitive limit that produced the alternatives

Every alternative test is a reaction to the same feature of the M'Naghten rule: it is pitched wholly at knowledge. It asks what the accused was able to know at the moment of the act, and it asks nothing about whether he could govern his conduct once he knew. That leaves a real clinical population unaddressed, the patients whose illness spares cognition but wrecks control, and it was pressure from those cases that drove the reform. Each successor test loosens exactly one constraint and no more, which is why the comparison between them is so clean.

The first line of attack adds a faculty. If a man can know an act is wrong and still be unable to resist it, then a test confined to knowing is incomplete, and the volitional element must be admitted alongside it. The second line of attack abandons the enumerated faculties altogether and asks only about origin: never mind whether he knew or could resist, did the illness cause the act? The third line of attack keeps both faculties but attacks the threshold, replacing total incapacity with a partial one and replacing bare knowledge with a fuller grasp. These are the only three moves available, and the three examinable tests are one each.

RULE **Each alternative broadens the insanity defence along one axis and no more.** Irresistible impulse adds the volitional faculty to a test that had asked only about knowledge; the product test discards the faculties and substitutes causation; the American Law Institute test keeps both faculties but softens the threshold from total to partial incapacity. Identify which axis a test moves and you have understood it.

22.2 The irresistible impulse test

The earliest and most modest departure from the cognitive rule is the **irresistible impulse** test, which does not replace M'Naghten but supplements it. It concedes the cognitive question and then adds a volitional one: the accused may be excused even though he could tell right from wrong, if a diseased mental condition deprived him of the power to resist the impulse to act. Its

classic wording comes from **Smith v. United States**, a District of Columbia decision later quoted in full in the leading product-test judgment. An accused may be excused only where, although able to distinguish right from wrong, his reasoning powers were so far dethroned by a diseased mental condition as to deprive him of the will power to resist the insane impulse to commit the act, though he knew it to be wrong.

Several features of that formulation are worth fixing, because examiners test the discriminations rather than the slogan:

- It presupposes that the cognitive test has been failed on its own terms; the accused did know the act was wrong, so the excusing element is loss of control, not loss of knowledge.
- The impotence of will must be the product of a diseased mental condition, not of ordinary rage, jealousy or intoxication, which is what keeps the test from swallowing every crime of passion.
- It works only as a gloss on M'Naghten, a volitional limb bolted to a cognitive frame, never as a free-standing code of its own.

The objection to the test is evidential rather than logical. No examination distinguishes an impulse that genuinely could not be resisted from one that simply was not resisted, and a court is left accepting an expert's inference about a capacity that leaves no external trace. That difficulty is why the jurisdictions that adopted the test confined it to cases where the collapse of self-control was close to total, and why later reformers preferred a formulation that spoke of degrees of capacity rather than of a single, unprovable moment of surrender.

22.3 The Durham or product test

The boldest experiment swept both the cognitive and the volitional questions aside and asked one thing only. In **Durham** v. United States, decided by the District of Columbia Circuit in **1954**, the court held that an accused is not criminally responsible if his unlawful act was the **product** of mental disease or mental defect. This is the broadest of all the tests: it names no symptom, ties the jury to no particular faculty, and makes the whole enquiry one of causation. It was modelled on an older **New Hampshire rule** that had similarly refused to reduce insanity to a fixed legal formula and had left the question of mental disease to the jury as a matter of fact.

Its breadth was both its appeal and its undoing. By asking only whether the crime issued from illness, the product test allowed the full clinical picture to come before the court and freed psychiatry from having to force its findings through the narrow language of knowing and resisting. But the same breadth cut loose the legal question from any workable standard. With no definition of mental disease and no symptom for the jury to look for, the determination drifted toward whatever the expert witnesses asserted, and the phrase mental disease itself proved unstable as diagnostic fashions shifted. Critics charged that the test surrendered a question of moral and legal responsibility to clinical opinion. The verdict was delivered by the very court that had created the rule: in United States v. **Brawner** it abandoned the product test and adopted the American Law Institute formulation in its place. The product test survives in the examination

chiefly as the cautionary extreme, the demonstration of what happens when the insanity enquiry is made too wide.

22.4 The American Law Institute Model Penal Code test

Between the rigidity of M'Naghten and the formlessness of Durham sits the considered compromise, the test drafted for the **Model Penal Code** at section **4.01**. Its wording restores both faculties while lowering the bar for each. A person is not responsible for criminal conduct if, at the time of the conduct, as a result of mental disease or defect he lacks substantial capacity either to appreciate the criminality, or wrongfulness, of his conduct, or to conform his conduct to the requirements of law. The cognitive and the volitional questions are set in the alternative, joined by an "or", so that a failure of either capacity suffices.

Two changes of language carry the whole reform, and both are examined:

- The test asks whether the accused could **appreciate** the wrongfulness of the act, not merely whether he could know it. Appreciation implies an emotional and rational grasp of meaning, deeper than the bare intellectual awareness the older word demanded, and it admits the defendant who could recite that an act was forbidden without truly understanding what that meant.
- The test requires only that the accused lack **substantial capacity**, not that he be wholly incapable. This deliberately abandons the all-or-nothing quality of the older tests and lets the law recognise the partial impairments that clinical reality actually presents.

The drafters also closed the obvious loophole. The formulation expressly excludes an abnormality manifested only by repeated criminal or antisocial conduct, so that a diagnosis resting on the offending record itself cannot be used to bootstrap the defence; the habitual offender cannot convert his history of crime into evidence of the disease that excuses it. Taken together, the test spread across most of the American federal circuits as the settled middle path, until the volitional half of it fell out of favour after a notorious acquittal. The Insanity Defense Reform Act of **1984** removed the volitional prong from federal law, returning the federal test to an appreciation-of-wrongfulness standard and leaving the two-limbed version to those states that retained it.

TRAP **Presenting the product test or the Model Penal Code volitional prong as the current American standard.** The product test was abandoned by the same court that devised it, the District of Columbia Circuit, in Brawner, not by American courts generally, and the volitional limb was struck out of federal law by statute, though state rules still vary and some states retain a volitional element of their own. Write each as a landmark in a doctrinal arc, not as the rule in force everywhere, and never carry either into a statement of what every American court would apply today.

22.5 Reading the tests against one another

The examiner's favourite exercise is to set the tests side by side, and the discriminations are cleanest when each is measured against the M'Naghten baseline on two axes: the faculty it interrogates and the breadth it allows. The accompanying comparison arranges them so, from the narrowest cognitive rule to the widest causal one, with the compromise between.

MNEMONIC

Will, Cause, Both

The alternatives in one line: irresistible impulse tests the **will**, the product test tests **cause**, and the Model Penal Code test restores **both** faculties at a lower threshold. Set against M'Naghten, which tests knowledge alone, this fixes the whole family in memory and tells you at once what each one adds.

TEST	FACULTY IT INTERROGATES	CORE QUESTION	BREADTH AND CURRENT STANDING
M'NAGHTEN (THE BASELINE)	Cognition alone	Could he know the nature of the act, or that it was wrong?	Narrowest; the frame retained in India, taught in full elsewhere in this chapter
IRRESISTIBLE IMPULSE	Volition, added to cognition	Though he knew it was wrong, could he resist the impulse?	A gloss on the cognitive test, never free-standing; not accepted as such in India
DURHAM OR PRODUCT	Neither; causation only	Was the act the product of mental disease or defect?	Broadest; abandoned by the D.C. Circuit in Brawner, not nationwide
MODEL PENAL CODE	Cognition and volition	Did he lack substantial capacity to appreciate wrongfulness or to conform his conduct?	The middle path; the volitional half later dropped in federal law

1954	1962	1972	1984
DURHAM DECIDED	MODEL PENAL CODE TEST FRAMED	PRODUCT TEST ABANDONED	VOLITIONAL PRONG DROPPED, US FEDERAL

22.6 Why India keeps the M'Naghten frame

The alternatives are foreign-law history, not defences you can run here. The Indian insanity defence remains the cognitive right-and-wrong test. The current unsound-mind exception and the historical provision it replaced are set out in full under the McNaughton rules in this chapter, and what matters at this point is what they exclude. India never adopted the product test and never adopted the Model Penal Code standard, and its courts have generally not accepted irresistible impulse as a free-standing defence. Loss of control, by itself, does not answer the question the statute asks. It becomes relevant only where it can be shown to amount to an incapacity to know the nature of the act, that it was wrong, or that it was contrary to law, at which point it has stopped being a separate volitional test and has collapsed back into the cognitive one the Indian codes already contain.

The reasoning behind this conservatism is coherent rather than merely traditional. The cognitive test asks a question that can be reconstructed from evidence, whether the accused knew, and courts can weigh planning, concealment and flight against that claim. A volitional or causal test

asks a question that leaves no external trace and that the same reasoning cannot police, which is precisely the evidential objection that eventually narrowed the American tests too. India, in other words, reached the destination the American arc was travelling toward and simply never left it.

IN INDIA

An accused who knew his act was wrong but says he could not resist it does not, on that ground alone, satisfy the Indian test; a defence pitched purely on loss of control has no statutory footing here, and neither does one pitched on the act being a product of illness. The practical corollary is that an Indian forensic opinion is built around the accused's capacity to know the nature of the act, that it was wrong, or that it was contrary to law, at the material time, and the volitional and causal formulations enter, if at all, only as they bear on that cognitive question.

No alternative test is Indian law: India retains the M'Naghten cognitive frame, and its courts admit irresistible impulse only where it amounts to an incapacity to know the nature of the act, that it was wrong, or that it was contrary to law.

22.7 The alternatives in an Indian medico-legal opinion

The tests matter to the clinician chiefly as a discipline of drafting. A psychiatrist who has absorbed the Western literature naturally reaches for its vocabulary, and it is easy to write an opinion in language a foreign court would recognise but an Indian one cannot use. The examiner rewards the candidate who keeps the clinical description and the legal conclusion apart: describe the illness and its bearing on control and causation as fully as the record allows, then translate that description into the only question the Indian court is empowered to answer.

PITFALL

Offering, as the operative conclusion of a report for an Indian court, that the act was a "product" of the illness or that the accused acted on an "irresistible impulse". However accurate the clinical observation, the court has no test into which those words fit, and the opinion gives the judge nothing on which to decide. The error is one of scope rather than of assessment, and it is the counterpart on this topic of citing a superseded section as the live law.

GOOD TO REMEMBER

Describe volitional impairment and the illness-to-crime link freely in the clinical body of the report, because that is genuine and useful evidence, but anchor the conclusion to the question the law actually asks: at the material time, could the accused know the nature of the act and that it was wrong? Frame loss of control as bearing on that cognitive capacity, not as a test in its own right. The form of the report itself and the certification of the expert to give evidence belong to the Forensic ethics, consent and legal procedure notes.

23 · Fitness to stand trial (criteria, assessment)

A criminal trial is a contest the accused is meant to take part in. The adversarial process presumes a defendant who can hear the charge against him, follow the evidence as it unfolds, and

give his lawyer the instructions from which a defence is built. When mental disorder takes that ability away, to press on would be to try a person who cannot answer the case, which offends the most basic requirement of a fair hearing. So the law asks, before the trial begins and again if the question arises once it is under way, whether the accused can be tried at all. This is **fitness to stand trial**, the same idea the older courts called **fitness to plead**.

The marks gather here because the topic is small, self-contained, and constantly confused with a larger one. The words "unsound mind" appear and candidates reach at once for the insanity defence, answering a question no one asked. Fitness is about the present: can this person be tried now, and it is procedural. Criminal responsibility is about the past: what was his state of mind when he did the act, and it is substantive. Hold those two apart and the topic is clean; blur them and the whole answer slides off the point.

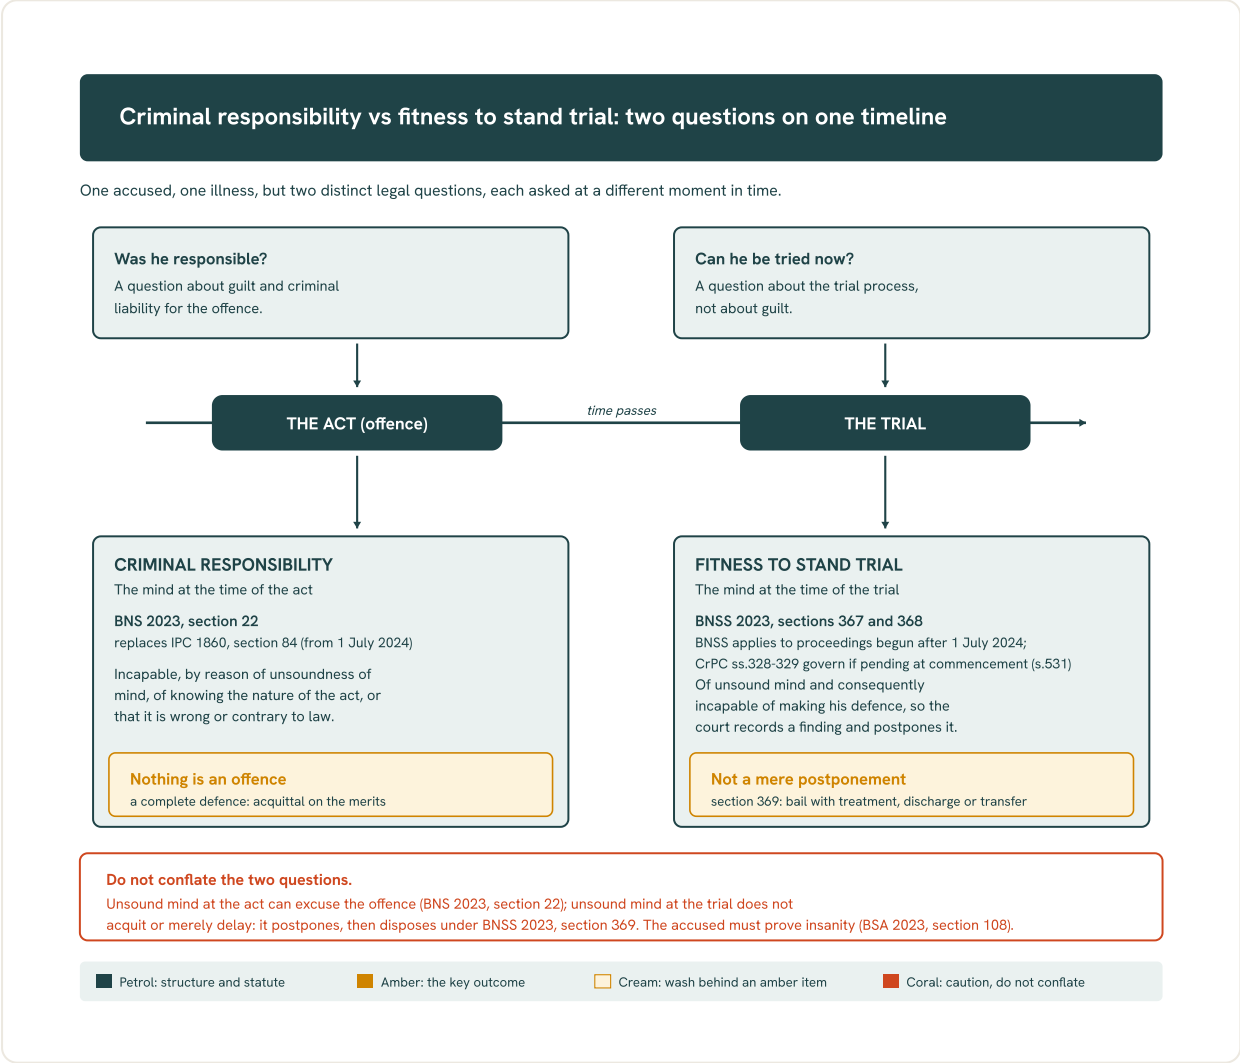

Fig 25.11. Criminal responsibility asks about the accused's mind at the time of the act (BNS 2023, section 22, replacing IPC 1860, section 84); fitness to stand trial asks about his mind at the time of the trial (BNSS 2023, sections 367 and 368). The first can excuse the offence. The second does not acquit and does not merely postpone the trial: on a finding of unfitness the court records the finding, postpones the proceedings, and then makes a disposal under BNSS 2023, section 369, which may release the accused on bail with out-patient treatment, order supervised treatment where bail is refused, discharge the accused on sufficient security, or transfer the accused to a residential facility.

23.1 What fitness to stand trial means

Fitness is the capacity to take part in one's own trial. It is not a measure of general mental health and it is not intelligence; it is a functional, task-specific competence, judged against what the trial actually asks a defendant to do. The statute does not grade the illness. It poses a consequence question: is the accused, by reason of **unsoundness of mind**, rendered **incapable of making his defence**. Two limbs have to be satisfied, and they are joined by the word "consequently": there must be a mental condition, and that condition must be the reason the accused cannot mount a defence. A severe diagnosis that leaves the defendant able to understand the charge, follow the proceedings and instruct counsel does not make him unfit; a less dramatic condition that dismantles those abilities does.

The reason the law insists on this threshold is not therapeutic but a matter of justice. A verdict reached against a defendant who could not understand the proceedings or contribute to his own defence is not a safe verdict, because the process that produced it was not one he could engage with. Fitness protects the integrity of the trial itself, which is why it is examined as a preliminary matter and can be raised at any stage the illness first shows itself, whether at the outset or midway through the hearing.

RULE **Unsoundness of mind bears on fitness only where it makes the accused incapable of making his defence.** The test has two limbs and the second decides it. Establish a mental condition and you have done the first half; what settles fitness is the functional bridge from that condition to the specific abilities a defence requires. A diagnosis, however grave, is not by itself a finding of unfitness, and the absence of florid symptoms is not by itself a finding of fitness.

23.2 Fitness set against criminal responsibility

This is the discrimination the topic is really testing, and it is worth stating in full because so many answers lose their footing on it. The two questions differ on their timeline, their purpose and what a finding does. Fitness looks at the accused as he is at the time of trial and asks whether he can participate; a finding of unfitness suspends the proceedings but says nothing about guilt. Criminal responsibility looks back to the time of the act and asks whether the accused should be held liable for what he did; it is a defence to the charge, decided at trial as part of the verdict. Whether unsoundness of mind at the moment of the offence exempts the accused from liability is governed by the substantive criminal law, now recast in the Bharatiya Nyaya Sanhita in place of the Indian Penal Code, and is taken up elsewhere in this chapter under the insanity defence. It is not restated here.

Because the two run on different axes, they can appear in any combination, and this is what makes them genuinely independent rather than two names for one idea. A defendant may be perfectly fit to stand trial and still argue that he was insane at the time of the act; another may have been fully responsible when he offended but become unfit, through illness arising afterwards, by the time the case reaches court. The first is tried and runs his defence, insanity included; the second cannot be tried at all until he is well enough, and the question of his responsibility simply waits for him. Confusing the two collapses this structure and produces an answer that assesses the wrong moment and the wrong issue.

TRAP **Describing the insanity defence when the question was about fitness.** The shared phrase "unsound mind" lures candidates into reciting the tests of criminal responsibility. But fitness is present-state and procedural and has nothing to do with the mental state at the time of the offence. If your answer is dating the accused's mind to when he acted, you have drifted into the wrong topic and will be marked on a question you were not asked.

Fitness to stand trial asks whether the accused can make his defence now and is decided by the court on medical and other evidence; criminal responsibility asks about his mind at the time of the act. They sit on different timelines and neither answers the other.

23.3 The criteria: what making a defence requires

The statute states the test as incapacity to make a defence and leaves the content of that phrase to be worked out in practice. Unpacked, making a defence calls for a cluster of abilities, each tied to a real demand the trial places on the defendant:

- to understand the charge he faces and what is being alleged against him;
- to understand the nature and object of the proceedings and their possible consequences;
- to follow the course of the evidence as it is given;
- to instruct and communicate rationally with his lawyer, giving the account from which a defence can be run;
- to make the decisions a defendant must make, including how to plead and whether to challenge the conduct of his trial.

These are abilities, not attainments: the law asks whether the accused can do these things, not whether he does them well or wisely. A defendant may make an unwise choice and remain fit, because unwisdom is not incapacity. Common-law systems have distilled the same cluster into named judicial standards, but those formulations are the property of other jurisdictions and are not set out here; what matters for the Indian answer is the functional content behind the statutory phrase, tested ability by ability against the disorder in front of you.

It helps to see how different conditions defeat fitness by different routes, because the assessment turns on the route, not the diagnosis. Acute psychosis may make it impossible to follow proceedings or to give a rational account; a severe mood or thought disorder may disorganise communication with counsel; intellectual disability or an acquired cognitive disorder may block understanding of the charge and its consequences; a profound disturbance of memory or attention may prevent the accused from tracking the evidence. The threshold itself, though, is participation rather than sophistication: the law wants a defendant who can engage with his trial, not one who could conduct it as a lawyer would. Setting the bar too high, so that only a mentally robust defendant counts as fit, misreads the standard as badly as setting it too low.

23.4 The statutory procedure: at inquiry and at trial

The code reaches the question both before and during trial, and gives each stage its own provision. At the inquiry stage, while a Magistrate is still examining whether a case should

proceed, section **367** governs. When the Magistrate has reason to believe the person before him is of unsound mind and consequently incapable of making his defence, he shall inquire into the fact of that unsoundness, and shall cause the person to be examined by the **civil surgeon** of the district or such other medical officer as the State Government may direct, examine that officer as a witness, and reduce the examination to writing. The provision continues an arrangement already present in the amended older law: where the civil surgeon finds unsoundness, the person is referred to a psychiatrist or clinical psychologist of a Government hospital or medical college for care, treatment and prognosis, with a right of appeal to a **Medical Board**.

Once the trial itself is under way, section **368** applies. If it appears to the Magistrate or Court of Session that the accused is of unsound mind and consequently incapable of making his defence, the court shall, in the first instance, try the fact of that unsoundness and incapacity; and if, after considering such medical and other evidence as is produced, it is satisfied of the fact, it shall record a finding to that effect and shall **postpone further proceedings**. Both provisions took effect on **1 July 2024**, replacing the corresponding sections of the former Code of Criminal Procedure.

The choice of verb is the whole of the duty. In both provisions it is expressed as "shall", not "may". The court is not given a discretion to try a defendant it suspects is unfit and settle the point later; the moment unfitness is genuinely in issue, it must be tried first, as a preliminary fact, on medical and other evidence, before the substantive trial can go any further. This ordering, the fact of unfitness decided ahead of the question of guilt, is the structural point candidates most often lose, and it is why an answer that reduces the duty to a discretionary power misstates the provision.

FEATURE	INQUIRY STAGE	TRIAL STAGE
When it operates	During the Magistrate's inquiry, before the trial proper	Once the trial is under way, before a Magistrate or Court of Session
What triggers it	The Magistrate has reason to believe the person is of unsound mind and incapable of making his defence	It appears to the court that the accused is of unsound mind and incapable of making his defence
Mandatory medical step	Shall cause examination by the civil surgeon or a directed medical officer, examine him as a witness and reduce it to writing, with onward referral to a psychiatrist or clinical psychologist and an appeal to a Medical Board	Shall first try the fact of unsoundness and incapacity on medical and other evidence
Effect of a positive finding	The fact is recorded and the person is directed to care, treatment and prognosis	Shall record a finding of unsoundness and incapacity and postpone further proceedings

367	368	1 Jul 2024
INQUIRY STAGE	TRIAL STAGE	SANHITA IN FORCE

IN INDIA

This topic runs on the Bharatiya Nagarik Suraksha Sanhita for proceedings instituted after the sanhita's commencement, and on the former Code of Criminal Procedure for any trial, inquiry or other proceeding pending immediately before that commencement, which the sanhita's own savings clause keeps alive as governing law. The machinery is distinctly Indian and the two stages take separate routes: at the inquiry stage the first medical opinion comes from the civil surgeon of the district or a medical officer the State Government names, with onward referral of a person found to be of unsound mind to a psychiatrist or clinical psychologist of a Government hospital or medical college for care, treatment and prognosis, and a route of appeal to a Medical Board; at the trial stage the court instead refers the accused directly to a psychiatrist or clinical psychologist, not through that same civil-surgeon-first sequence. Neither the referral to a psychiatrist or clinical psychologist nor the Medical Board appeal is a sanhita innovation: both continue an arrangement the amended older code already carried. A candidate who cites the old code's section numbers as the governing law is right where the proceeding was pending immediately before commencement, and wrong only where it was instituted afterward.

23.5 Assessing fitness: the psychiatrist's task

The referral you receive is narrower than it first looks. The court does not want a global opinion on the accused's mental health; it wants to know whether a mental condition is present and, if it is, whether it strips him of the particular abilities that making a defence requires. The assessment therefore runs on two tracks at once: a clinical evaluation to establish diagnosis and current mental state, and a functional evaluation that tests each defence ability against that state. Can he tell you what he is charged with. Can he follow what is happening in court and why. Can he give a coherent account to his lawyer and take part in decisions about his own case. The opinion is built from the answers, ability by ability, with the disorder linked explicitly to any incapacity found rather than assumed from the label.

Two features of the judgement are easy to forget. Fitness is present-state and can change: a person who is unfit in acute illness may become fit with treatment, so an opinion is a snapshot and may need revisiting as the condition moves. And the determination is ultimately the court's, not the clinician's. The statute has the court decide the fact on medical and other evidence, which places the psychiatrist as an expert witness supplying one input to a judicial finding, not as the person who makes it. Overstating the role, and writing an opinion as though it were the verdict, is a common way for a report to exceed its proper reach.

PITFALL

The commonest clinical error is to let the diagnosis do the work, certifying a psychotic or intellectually disabled accused unfit because he is unwell, without asking whether the illness actually disables the tasks of making a defence. Fitness is task-specific: a person with a serious disorder may still understand the charge, follow the evidence and instruct counsel, while another whose diagnosis looks milder may be unable to do any of these. Assess the abilities, not the label, and show the link between them.

GOOD TO REMEMBER

When you are asked to opine on fitness, build the report around the defence abilities themselves, understanding of the charge and the proceedings, the ability to follow evidence, and the ability to instruct counsel and decide on a plea, and state, for each, how the disorder does or does not impair it. Keep in view that you supply medical evidence and the finding is the court's to make. The form the report or certificate takes for the court, and the ethics of giving expert evidence, belong to the Forensic ethics, consent and legal procedure notes.

23.6 After a finding of unfitness

A finding of unfitness stops the trial; it does not end the case, and it is not a single order that merely freezes the clock. The court's first duty is to try the fact of incapacity itself, and once incapacity is found the disposal forks rather than defaulting to postponement. Where the evidence produced discloses no prima facie case for the accused to answer, he is discharged rather than held; where a prima facie case remains, the court records the finding of unsoundness and incapacity and postpones further proceedings so that treatment can begin. Postponement is therefore one branch of the disposal, not the whole of it, and the accused who is postponed stands neither acquitted nor convicted, the trial suspended and waiting for him. The sanhita's orientation is treatment and restoration rather than indefinite removal: at the inquiry stage the person is routed to care, treatment and prognosis, and the object is to restore fitness so that the trial can resume and the substantive questions, including responsibility for the act, can finally be answered by a defendant able to meet them.

What becomes of the accused once he is found incapable is set out separately. Where a person is found under section **367** or section **368** to be incapable of making his defence, section **369** governs his disposal, and it offers a graded set of outcomes rather than bare custody. On medical opinion the court may release him on bail where his condition does not require in-patient treatment and a relative or friend undertakes to secure regular out-patient psychiatric treatment and to prevent harm; where bail cannot be granted or no such undertaking is given, it orders him kept in a place where regular psychiatric treatment can be provided. Weighing the nature of the act committed and the extent of the unsoundness of mind or intellectual disability, the court then determines whether release can be ordered at all: it may discharge him on sufficient security, or, where discharge cannot be ordered, transfer him to a residential facility for care and training. Release on bail with an out-patient undertaking, supervised treatment where bail is refused, discharge on sufficient security and transfer to a residential facility are the real branches after a

finding of unfitness; the topic is not, as candidates too often write it, a single order that only postpones the proceedings.

The harder cases are those where fitness may never return. Postponement assumes restoration, but a defendant with a progressive dementia or a fixed cognitive deficit may remain permanently unable to be tried, and the law must then balance the public interest in a trial and the protection of others against the injustice of holding an untried person indefinitely. How the system resolves that tension turns on the disposal choices just described, weighed against the nature of the act and the extent of the disorder, but the clinician should recognise the problem, because a prognosis on the likelihood and timescale of restored fitness is often the most useful thing the psychiatric opinion can offer the court.

The one matter left open here is the mechanism by which proceedings are taken up again once fitness returns, which is set out in further provisions of the sanhita not detailed in these notes. One route in particular should not be confused with fitness at all: the preliminary assessment of a child in conflict with the law, which decides whether a juvenile is dealt with as an adult, is a different determination under a different statute and belongs to the Child psychiatry: assessment, treatment, services and protection notes, not to the law of fitness to stand trial.

24 · Diminished responsibility and automatism

Why the marks are here. Once a court accepts that a defendant performed the physical act, it can still be asked whether the mind behind that act was whole enough to carry the full weight of the charge. Two doctrines press exactly at that seam. **Diminished responsibility** is the claim that a mental abnormality, without excusing the killing, was serious enough to lower its grade; **automatism** is the stronger claim that the act was performed with no conscious control at all. An Indian paper examines the two together because the Indian answer to each is not the English textbook one: a candidate who reaches for the familiar Western framework describes a defence that does not exist here and misses the one that does.

The disciplined way to hold this whole topic is to see that Indian criminal law keeps no separate compartment for either idea. It does not grade criminal responsibility on a sliding scale, and it does not name automatism as a defence in its own right. Instead it feeds each question into a category it already possesses: the grade of a homicide can be softened on a mental ground through provocation, and an act said to be involuntary is answered through the unsound-mind exception where that exception's cognitive-incapacity test is actually met, though that exception is not the sole route by which an alleged involuntary act is examined. This routing, provocation for the grade of a killing and the unsound-mind exception for an involuntary act, is the long-established position of Indian criminal law, and these notes state it on that footing; the precise section of the recodified penal code, the Bharatiya Nyaya Sanhita, that now carries the grave-and-sudden-provocation exception has not been reconfirmed against the primary statute in preparing these notes, so it is named here without its number. Everything that follows is an unpacking of that single structural fact.

India has no diminished-responsibility defence; grave and sudden provocation is the partial defence nearest in effect to it, reducing murder to culpable homicide not amounting to murder, and automatism is answered through the unsound-mind exception when it arises from a disease of the mind.

1957	three	two
ENGLISH HOMICIDE ACT	AUTOMATISM STATES	INSANE OR SANE

24.1 Diminished responsibility: the partial defence India did not adopt

Diminished responsibility originated in Scots law and was introduced into England and Wales by the English Homicide Act of **1957**; there, it is a partial defence to murder alone. It concedes that the accused killed unlawfully, but argues that an abnormality of mental functioning, arising from a recognised medical condition, substantially impaired the capacity to understand the conduct, to form a rational judgement, or to exercise self-control, and provides an explanation for the killing, and so reduces the conviction from murder to the lesser homicide offence with its wider sentencing range. This current test followed the Coroners and Justice Act 2009 amendment to the 1957 device, and its defining feature is that it works on the grade of the offence rather than on guilt: the defendant is neither acquitted nor treated as fully responsible, but left in an intermediate position.

Indian law contains no equivalent. Its general exception for unsoundness of mind operates as a complete defence or as none at all, so there is no statutory instrument that recognises impaired-but-not-abolished capacity and lowers the charge on that account. A defendant whose disorder clouded but did not extinguish the relevant mental capacity falls outside the mental exception altogether, because that exception, whose test and current penal-code provision are set out elsewhere in this chapter where the insanity defence and the McNaughton rules are discussed, is written in all-or-nothing terms. Such a disorder may still weigh in mitigation when the judge fixes sentence, but that is judicial discretion applied after conviction, not a defence that alters the verdict. The absence of the intermediate rung is deliberate, and it is examined precisely because candidates assume the English ladder is present.

24.2 Grave and sudden provocation: the nearest partial defence to murder

The one place where Indian law does soften a killing on something like a mental ground is provocation. Where the accused is deprived of the power of self-control by provocation that is both grave and sudden, and in that state causes the death of the person who gave the provocation, or of another person by mistake or accident, the offence is brought down from murder to **culpable homicide not amounting to murder**. The exception is lost on any of three provisos: where the accused sought or voluntarily provoked the provocation as an excuse for killing or causing harm, where the provocation was given by something done in obedience to the law or by a public servant acting lawfully within the powers of that office, or where the provocation was given by something done in the lawful exercise of the right of private defence. Whether the provocation was in fact grave and sudden, and whether the accused acted while actually deprived of self-control, is a question of fact for the court on the circumstances of each

case. This is the true counterpart to diminished responsibility in the Indian scheme, because it is a genuine partial defence: it does not acquit, it re-grades. The comparison the examiner wants is that both doctrines lower a murder charge without excusing it, but they rest on entirely different foundations.

Grave and sudden provocation is not a defence of mental incapacity. The accused is treated as responsible, and the law makes a limited concession to ordinary human frailty rather than to illness. Its logic carries both an objective and a subjective element: the provocation must be grave enough that it could deprive a reasonable person of self-control, and it must in fact have deprived this accused of self-control at the moment of the act. The requirement that it be sudden weighs heavily against the exception where a real interval allowed the passions to cool, but the point is not automatic: whether the exception is made out remains a question of fact, and if it fails, on this or any other ground, the remaining ingredients of murder and any other applicable exception must still be established before a murder conviction follows. The psychiatrist's role here is narrow and easily overstated: an opinion on temperament or a co-existing condition may be sought, but the defence itself is a legal construct the court applies, not a psychiatric plea.

FEATURE	DIMINISHED RESPONSIBILITY (THE ENGLISH PARTIAL DEFENCE)	GRAVE AND SUDDEN PROVOCATION (THE INDIAN PARTIAL DEFENCE)
What it rests on	An abnormality of mental functioning that substantially impaired a relevant capacity	Loss of self-control caused by provocation, in a person treated as responsible
Effect on the charge	Reduces murder to the lesser homicide offence	Reduces murder to culpable homicide not amounting to murder
Nature of the concession	To mental illness or abnormality	To human frailty, not to illness
Available in Indian law	No such free-standing defence exists	Yes, as a recognised exception to murder

24.3 Automatism: the concept and the states behind it

Automatism is the assertion that the body acted while the mind was not consciously directing it, so that the movement, though it caused harm, was not a willed act of the person at all. It bites deeper than any partial defence because it attacks the voluntariness a criminal act presupposes: if the conduct was truly involuntary, the guilty act and guilty mind the law requires, analysed elsewhere in this chapter where mens rea and actus reus are set out, are simply not made out. The plea is therefore about absence of conscious, voluntary control at the material time rather than about impaired judgement.

Clinically it is raised by a small set of transient states in which awareness and volition are genuinely suspended:

- the post-ictal state that can follow a seizure, with confused, automatic behaviour;
- a hypoglycaemic state, in which falling glucose disorganises conscious control;

- a somnambulistic state, in which complex acts are carried out during **somnambulism** without waking awareness.

The trap for the clinician is to think the diagnosis settles the law. It does not. The legal category is not the medical label but the answer to two prior questions: was conscious voluntary control actually absent when the act was done, and what caused its absence. A further variant, automatism attributed to voluntary intoxication, is governed by the separate law on intoxication rather than treated as automatism proper, and the clinical management of substance use itself belongs to the Substance use disorders notes.

24.4 Insane versus sane automatism: the internal and external divide

English common law sorts automatism not by its clinical name but by its cause: this internal/external classification is the comparator, not enacted Indian law. Where the involuntary act springs from a **disease of the mind**, an internal cause, English law classes it as **insane automatism** and deals with it as insanity is dealt with; where the involuntary act springs from a purely external cause, English law classes it as **sane automatism**, which if accepted there points toward an ordinary acquittal. India has no separately codified automatism defence carrying either label. A disease-linked involuntary act reaches the unsound-mind exception only where that exception's cognitive-incapacity test is actually met; where it is not, or where the alleged cause is external, the Indian court must assess voluntariness, the ingredients of the charged offence and any applicable statutory exception directly, without a promised codified acquittal.

The pivot, disease of the mind, is a legal construct and not a psychiatric one, and English courts have read it broadly, turning on whether the cause is internal to the person and liable to recur. The reason English law works so hard at this line is that its two branches lead to opposite destinations there: insane automatism, treated as unsoundness of mind, leads not to freedom but to the disposal that follows a successful mental exception, with its provision for detention and treatment; sane automatism, if made out, ends in a clean acquittal. India draws no equivalent guarantee for either branch: an Indian court reaches the insanity disposal only where the unsound-mind exception's own test is met, and has no codified route promising sane automatism an acquittal, so it works from voluntariness, the offence's ingredients and any applicable exception rather than from the common-law label. Because releasing a person whose brain may repeat the act carries a public-protection cost, English courts are cautious about the external-cause branch and readier to route a recurring internal condition through the insanity route.

MNEMONIC

Inside the mind, insane; outside the mind, sane

An internal cause, a disease of the mind, makes the automatism the insanity question and sends it into the unsound-mind exception; an external cause makes it sane automatism, a common-law route to acquittal that Indian statute does not separately codify. Sort by where the cause sits, not by the diagnosis on the chart.

AXIS	AUTOMATISM FROM A DISEASE OF THE MIND	AUTOMATISM FROM AN EXTERNAL CAUSE
Common-law label	Insane automatism	Sane automatism
Where the cause lies	Internal to the person, liable to recur	External to the person
Route in Indian law	Answered through the unsound-mind exception, only where its cognitive-incapacity test is met	Not a separately codified Indian route; the court assesses voluntariness, offence ingredients and any applicable exception directly
Direction of outcome	Toward the insanity disposal, with detention and treatment, where the exception is made out	Under the common-law comparator, toward an ordinary acquittal; Indian law promises no codified route to that outcome

RULE **Neither doctrine is a free-standing Indian defence; each is routed into a category the law already holds.** A killing is down-graded on a mental ground through grave and sudden provocation, the nearest analogue to diminished responsibility rather than the only exception that reduces murder to the lesser offence, and an act said to be involuntary that stems from a disease of the mind is justiciable through the unsound-mind exception where its test is met, though that exception is not the sole route by which an alleged involuntary act is examined. Automatism from an external cause survives as a common-law idea that Indian statute does not separately name, and an Indian court assesses such a case directly on voluntariness, the offence's ingredients and any applicable exception.

24.5 The forensic assessment, and the errors it invites

What the psychiatrist actually supplies. Because both questions turn on a mental state at a past instant, the assessment is functional and almost always retrospective. The task is to reconstruct, from contemporaneous records, witness accounts of the act itself, the person's own account and the known pattern of the condition, whether conscious voluntary control was present or absent at the material time, and to form a view on the likely cause and whether it amounts to a disease of the mind. What the psychiatrist supplies is a medical opinion; the legal category, whether the automatism is insane or sane, and whether responsibility stands, is the court's to decide. An honest report says where the contemporaneous evidence is thin and frames its conclusion as an inference, because a bare diagnosis neither proves nor disproves that the act was involuntary. The conventions for putting that opinion before a court, and the certification of an expert to testify, are not part of this substantive law and belong to the Forensic ethics, consent and legal procedure notes.

GOOD TO REMEMBER

Anchor the opinion to the moment of the act and its cause, not to the label. Ask whether conscious voluntary control was present when the act occurred and whether the cause is internal and recurrent, because that placement, not the name of the condition, decides which legal route the automatism takes. Where the records will not support a firm view, say the evidence is insufficient rather than fill the gap with an impression.

IN INDIA

In practice a referral labelled as automatism is, more often than not, the insanity question in another dress, because the internal-cause states that reach a court, such as post-ictal or somnambulistic behaviour, are the ones the law treats through the unsound-mind exception. The useful Indian report translates the clinical picture into terms the law can act on, points the recurring internal condition toward that exception, and does not offer a diminished-responsibility verdict Indian law cannot receive.

TRAP **Answering as though India had a diminished-responsibility defence, or treating automatism as a distinct Indian plea.** The marks come from knowing that India routes both questions through existing categories: provocation for the grade of a homicide, and the unsound-mind exception for automatism that arises from a disease of the mind. Importing the English partial defence, or presenting sane automatism as a codified Indian defence, is the classic way to lose an answer that structure would have secured.

PITFALL

Writing the wrong law into a real medico-legal report. Offering "diminished responsibility" as an available Indian plea, or citing the superseded penal code as the live provision, does not merely lose an examination mark; it discredits the report and the witness, because the opposing side need only point out that the doctrine or section relied upon is not the law in force. Frame the opinion in the categories Indian law actually uses, and leave the legal conclusion to the court.

25 · Mens rea, actus reus and legal concepts of intent

Where forensic psychiatry enters the criminal law. When a court asks whether a mentally ill person can be convicted of a crime, it is really asking about two building blocks the law has used for centuries: was there a prohibited act, and was there a guilty mind behind it. Almost every forensic-psychiatric opinion in a criminal matter, whether it concerns the insanity defence, diminished responsibility, automatism or fitness to plead, is in the end an argument about one of these two blocks, and most often about the second. Grasping **actus reus** and **mens rea** is therefore not abstract jurisprudence for the candidate; it is the grammar in which the psychiatrist's evidence has to be written if it is to be admissible and useful.

The marks reward the candidate who keeps the legal categories and the clinical ones apart: a diagnosis is not a defence, and a symptom is not the absence of intent. The disciplined witness translates a psychiatric finding into the language of the mental element and stops there, leaving the verdict to the court.

25.1 The two elements of a criminal offence

An ordinary criminal offence is built from **two** elements that the prosecution must establish together: a prohibited act and the guilty mind that accompanies it. The external element is the *actus reus*, the conduct the law forbids; the internal element is the *mens rea*, the blameworthy state of mind with which that conduct is done. Neither is sufficient on its own. A person who forms a murderous wish but does nothing has no act and commits no offence; a person who

causes harm by pure accident, without any of the mental states the law demands, has done the act but without the guilty mind. Only where both are present, proved to the criminal standard, can a conviction follow.

MNEMONIC

Actus non facit reum nisi mens sit rea

"An act does not make a person guilty unless the mind is also guilty." The single line encodes the whole topic: the forbidden **act**, the guilty **mind**, and the requirement that the two belong to the same event. Every criminal-responsibility defence works by attacking one half of it.

AXIS	ACTUS REUS	MENS REA
What it is	The external, prohibited element: conduct, its surrounding circumstances and, for result crimes, its consequence	The internal, blameworthy element: the state of mind accompanying the act
What the law asks	Did the accused do the forbidden thing, and do it voluntarily?	With what intention, knowledge or awareness of risk was it done?
How it can be missing	An involuntary movement, or conduct the law does not in fact prohibit	Accident, mistake, or a mind the law treats as incapable
Where psychiatry usually bears	Rarely, automatism being the exception	Commonly, the psychiatric opinion speaking to the capacity for the required mental state

RULE **The act and the guilty mind must coincide.** It is not enough that each existed at some point; they must meet in the same transaction, the mental element present at the moment the prohibited act is done. This concurrence principle is why timing dominates a forensic opinion: the evidence must fix the mental state to the material time, not to the assessment carried out months later, because a disturbance that arose only afterwards leaves the offence intact.

A crime needs both a forbidden act and the particular guilty mind the law specifies for it, present together at the same moment; prove one without the other and there is no offence.

2	both
ACT AND GUILTY MIND	MUST CONCUR

25.2 The actus reus: the external element

The actus reus is more than a bodily movement. It is usually analysed as up to three things the prosecution may have to prove: the conduct itself, the surrounding circumstances that make that conduct criminal, and, for offences defined by their outcome, the proscribed consequence. In a homicide the conduct is the assault, the circumstance is that the victim was a living person, and the consequence is the death.

- **Conduct** - the act, or in defined cases a failure to act.

- **Circumstances** - the facts that give the conduct its criminal character.
- **Consequence** - the proscribed result, for those offences defined by their outcome.

Two further ideas complete the external element. First, the conduct must be **voluntary**: the law attributes an act to a person only when it was a willed movement of the body. A reflex, a convulsion or a movement during a state of clouded consciousness may be legally involuntary, and this is the doorway through which automatism enters, a plea set out elsewhere in this chapter where diminished responsibility and automatism are discussed. Second, liability can arise from an **omission**, but only where the law imposes a duty to act, as a parent owes a child, so that the failure to discharge that duty becomes the forbidden conduct. For result crimes the prosecution must also prove **causation**, that the accused's act was in fact and in law the cause of the proscribed consequence; an intervening cause may break that chain. The psychiatrist is seldom the witness on causation, but should place it on the act side rather than the mental one.

25.3 The mens rea and the ladder of fault

Mens rea is not a single state but a graded ladder of culpability. The law recognises several mental states, and each offence specifies which one it requires; broadly, the graver the offence, the higher the fault demanded. Running from the most to the least blameworthy, the familiar forms are intention, knowledge, recklessness and negligence. **Intention** is the aim or purpose to bring about the prohibited result. Knowledge is awareness that a circumstance exists or that a consequence is practically certain to follow. **Recklessness** is the conscious taking of an unjustified risk, the accused having foreseen the possibility of harm and gone on regardless. Negligence is a failure to meet the standard of care a reasonable person would show; it is inadvertent, and it is judged against an external standard rather than against what the accused actually foresaw. In Indian usage, a rash act is not a synonym for a negligent one but a distinct alternative: rashness carries awareness of the risk, the accused proceeding in the hope or belief that the harmful consequence will not occur, so it sits closer to conscious risk-taking than to negligence's inadvertence.

FAULT STATE	WHAT THE ACCUSED'S MIND IS DOING	HOW IT IS TESTED
Intention	Aims at the result, or acts in order to bring it about	Subjective: what this accused meant
Knowledge	Is aware the result is practically certain, or that the circumstance exists	Subjective: what this accused knew
Recklessness	Foresees the risk and unreasonably runs it	Subjective foresight of the risk
Rashness	Foresees the risk and proceeds, hoping or believing the harm will not occur	Subjective: the accused's own awareness of the risk
Negligence	Fails to advert to a risk a reasonable person would have seen	Objective: the reasonable-person standard

Why the ladder matters to the witness. A mental illness does not act uniformly on every rung. A disorder may leave a person able to intend an act at the level of bare purpose while destroying the higher-order appreciation that it was wrong, or leave intention untouched and bear only on the judgement of risk. Mapping the clinical picture onto the specific fault state the charge requires, not onto culpability in general, is the discipline that turns a diagnosis into evidence a court can use.

25.4 Legal concepts of intent

Intent in law is narrower and more technical than in ordinary speech, and several distinctions earn marks. Direct intention is the straightforward case, where the consequence is exactly what the accused wanted. Courts also recognise a form sometimes called oblique or indirect intention, where the accused did not desire the result but foresaw it as a virtually certain side effect of what they did set out to do, and from such foresight a court may infer intention. A second concept, **transferred intent**, applies where the accused directs a criminal intent at one target but the harm falls on another: the intent is carried across to the actual victim, so that aiming at one person and killing a bystander is still an intentional killing. And because intention is a fact about a person's mind, it is almost never proved directly. It is inferred from conduct and circumstance, on the common-sense premise that a person ordinarily intends the natural consequences of their acts, which is a presumption of evidence and not a rule that fixes the mind against contrary proof.

TRAP **Confusing motive with intention.** **Motive** is the reason behind the act, such as jealousy, gain or revenge; intention is the decision to do the prohibited act itself. Motive is generally irrelevant to guilt: a mercy killing and a killing for money share the same intention to cause death, and a benign motive does not erase mens rea. Candidates lose marks by arguing that a sympathetic motive negates intent. Motive can help to prove or disprove intention as a piece of evidence, but it is not itself the mental element.

25.5 When the guilty mind is dispensed with, or treated as absent

The requirement of a guilty mind is displaced in two very different ways, and the candidate should not run them together. At one end sit **strict-liability** offences, where the law dispenses with proof of mens rea for some or all elements of the act; the prosecution need only show that the accused did the prohibited thing. These are typically regulatory or public-welfare offences, where the social interest in deterrence is thought to justify convicting without an inquiry into fault. They are the exception, not the rule, and the graver the offence and its penalty, the more strongly the courts resist reading the mental element out of it. At the other end sits the **insanity exception**, and here the candidate should resist collapsing it into a mens-rea-negating device. The current Indian provision is a complete statutory General Exception in its own right, analytically distinct from the prosecution's separate obligation to prove the offence-specific mental element, not a rule that simply deems mens rea absent. An accused can form the intention to perform the physical act and still fall within the exception, because it asks a different question: whether unsoundness of mind removed the capacity to know the act's nature, or that it was wrong or contrary to law. Insanity evidence can also, independently of the exception, raise a reasonable doubt about an offence's own mental element; the two routes carry different burdens

and are not to be run together. That overlap without identity, not a straightforward negation of the mental element, is the conceptual bridge from psychiatry to the criminal law. Its full statement, the governing test, the current Indian substantive provision and the burden of proof, is developed elsewhere in this chapter where the insanity defence is set out; what matters here is that the exception may overlap with, but is not the same thing as, an absence of mens rea.

IN INDIA

Indian penal law does not leave the guilty mind to a single overarching doctrine. It writes the fault element into each offence through defined mental-state words, such as voluntarily, dishonestly, fraudulently, with intent, knowingly, rashly or negligently, and the statutory definitions of those words do much of the work the common law leaves to the maxim. The courts read a presumption of mens rea into an offence unless the statute clearly excludes it, while accepting genuine strict-liability offences in regulatory fields. The forensic implication is practical: identify the exact fault word the charge uses, because the opinion must speak to that mental state and no other.

25.6 The forensic psychiatrist and the mental element

For the psychiatrist, the framework defines both the question and its limits. The court does not want a diagnosis; it wants to know whether, at the material time, the accused had the capacity for the mental state the charge requires. The opinion should reconstruct that mental state as it was when the act was done, from history, contemporaneous records and the phenomenology, and relate it to intention, knowledge, awareness of risk or knowledge of wrongfulness, as the charge demands.

GOOD TO REMEMBER

Frame the report around the mental element, not around the verdict. Say what the illness did to the accused's capacity to intend, to know or to appreciate wrongfulness at the time of the act, and let the court draw the legal conclusion. Anchoring every statement to the material time, and separating what the illness explains from what it might excuse, is what makes the evidence admissible and hard to shake under cross-examination. The manner of putting that opinion before a court, and the certification of an expert to testify, belong to the Forensic ethics, consent and legal procedure notes.

PITFALL

Treating a diagnosis as though it were the absence of mens rea. A person can carry a serious mental illness and still have formed the intention, or possessed the knowledge, the offence requires; illness and an intact fault element routinely coexist. The clinical error is to reason from "the accused was psychotic" straight to "the accused had no guilty mind", skipping the step the law actually cares about, which is what the specific illness did to the specific mental capacity at the specific moment of the act. The report that names the disorder and stops has answered a medical question the court did not ask.

26 · Narcoanalysis, brain mapping and polygraph (deception detection, legal status)

Why the marks are here. Every so often an investigating agency, faced with a suspect who will not confess, reaches for a technique that claims to read the truth directly from the body or the brain. Three such techniques recur in the forensic setting - **narcoanalysis**, the **polygraph** and **brain mapping** - and together they make up the field of **deception detection**. The examiner is not testing the wiring of the machines. The marks are for three separate things a candidate must keep apart: what each technique actually measures, why its scientific standing is disputed, and, decisive for a court, whether the law permits it to be used at all and on what conditions. A candidate who can hold the technique and its admissibility apart answers the whole question; one who fuses them loses it.

These are investigative aids, not clinical tests. None of them makes a diagnosis, and none delivers a verdict of truthful or lying that a judge can simply adopt. Two neighbouring topics must be held off at the outset. The clinical detection of feigned or exaggerated illness, malingering, is a distinct skill and is set out elsewhere in this chapter; it borrows these instruments but does not own their legal status. And the professional-ethics questions the tests raise - consent for a purpose that is not the subject's own treatment, the psychiatrist acting for the investigator rather than the patient, and the report eventually placed before a court - belong to the Forensic ethics, consent and legal procedure notes. What this section owns is the trio of techniques and, above all, their legal position in India, which is settled and frequently examined.

26.1 The three techniques and what each claims to do

Narcoanalysis rests on a pharmacological idea. A sedative-hypnotic drug is given slowly into a vein and titrated to a drowsy, disinhibited, half-hypnotic state, on the theory that a person whose higher control is loosened can no longer sustain the effort of a deliberate lie and will let the truth slip out. The clinical reality is close to the opposite. The same disinhibition that is meant to release the truth also makes the subject highly suggestible and prone to confabulation, so that what emerges is an unstable mixture of memory, suggestion and invention. The account a subject gives under the drug is therefore not a faithful record of fact, and its value, where it has any, is as a lead to be independently verified rather than as evidence in itself.

The polygraph works on a physiological idea rather than a pharmacological one. It records several channels of autonomic arousal continuously while the subject answers a structured sequence of relevant and comparison questions, and the examiner infers deception from the pattern of reactivity, not from the words of the answer. The channels typically recorded are:

- respiration, its rate and depth;
- electrodermal activity, the sweat-gland or galvanic skin response;
- cardiovascular activity, the blood pressure and pulse.

The inference is only as strong as its central assumption, that lying reliably raises arousal more than truthful answering does, and that assumption is where the method is most exposed. Brain mapping, in the Indian forensic setting, refers specifically to the **Brain Electrical Activation**

Profile, an electroencephalographic method that presents the subject with crime-related probe stimuli and looks for the electrical brain response that signals recognition. Its logic differs from both the others: it does not claim to catch a lie but to detect experiential knowledge, that is, whether the brain treats a specific detail of the offence as already familiar, as it would be to a person who was present and not to an innocent stranger.

TECHNIQUE	WHAT IS RECORDED	INFERENCE DRAWN	PRINCIPAL WEAKNESS
Narcoanalysis	Speech produced in a drug-induced disinhibited state	That a disinhibited subject discloses withheld truth	Suggestibility and confabulation; the content is not reliable fact
Polygraph	Autonomic arousal across respiratory, electrodermal and cardiovascular channels	That deception raises arousal on the relevant questions	Arousal is non-specific; open to anxiety, countermeasures and examiner bias
Brain mapping	Electrical brain responses to crime-related stimuli	That the brain recognises a familiar detail of the offence	Detects recognition, not guilt; reliability disputed

26.2 Why the scientific standing is disputed

The reason all three are described as techniques of contested scientific validity is the same in each case: none of them measures deception itself. Each measures a proxy and then reasons backward from that proxy to a conclusion about truthfulness, and every step of the backward reasoning can fail. It is worth setting the criticisms out on principle, because the examiner rewards a candidate who can say why the methods are weak rather than merely assert that they are.

- the signal is indirect - pharmacological disinhibition, autonomic arousal, or stimulus recognition - and none of these is unique to lying, so an innocent explanation is always available for the same reading;
- the reading is examiner-dependent and defeatable: an anxious but honest subject can generate exactly the arousal that is scored as deception, a prepared subject can defeat the test with deliberate countermeasures, and interpretation is hard to standardise or replicate;
- there is no agreed, validated error rate for any of them that a court could weigh against the strength of the other evidence.

Narcoanalysis carries an additional and specific hazard, that its central mechanism is also a mechanism of false memory: the disinhibition that is supposed to lower the guard on the truth simultaneously lowers the guard on suggestion, so a leading question can plant an answer the subject then reports with conviction. The polygraph and brain mapping avoid that particular trap but share the deeper one, that a physiological or electrical correlate of arousal or familiarity is not the same thing as a lie. The distance between the correlate and the conclusion is precisely where an innocent person can be caught and a guilty one can slip through, and no amount of instrumental precision closes it, because the gap is one of logic and not of measurement.

26.3 The constitutional bar on compulsion

Where the examinable law sits. The Constitution guarantees, in Article **20(3)**, the **right against self-incrimination**: no person accused of an offence shall be compelled to be a witness against himself. The settled reading of that guarantee turns on a distinction between two kinds of evidence. A person may be compelled to furnish physical or material evidence - a fingerprint, a specimen, a handwriting sample - because giving it does not require the accused to speak from their own mind. A person may not be compelled to give testimonial or communicative evidence, evidence whose source is the content of the accused's own mind, because that is precisely to make them a witness against themselves.

The results of narcoanalysis, the polygraph and brain mapping fall, on this analysis, on the protected side of the line. Each extracts a communication from the subject's own mental processes - a spoken account, an autonomic reaction to a question, an electrical sign of recognition - so compelling the subject to undergo the test is compelling them to become a witness against themselves. In **Selvi v State of Karnataka (2010) 7 SCC 263** the Supreme Court held that the compulsory, involuntary administration of these techniques violates that right, and also the right to life and personal liberty under Article **21**, and that it amounts to cruel, inhuman or degrading treatment. The bar is thus doubly grounded: in the specific protection against self-incrimination and in the broader protection of personal liberty and dignity.

RULE **Compulsory administration is unconstitutional.** Forcing a subject to undergo narcoanalysis, the polygraph or brain mapping violates the right against self-incrimination and the right to life and personal liberty, and amounts to cruel, inhuman or degrading treatment. The prohibition attaches to the compulsion, not to the technique: what the Constitution forbids is extracting the mind's contents against the subject's will, whatever the instrument used to do it.

26.4 Consent, and the safeguards on a voluntary test

The consequence of the constitutional bar is a rule that is easy to state and easy to get subtly wrong: no such test may be conducted without the subject's **consent**. But consent is necessary, not sufficient. Compulsory testing is prohibited outright, and a voluntary request remains subject to judicial consideration and authorisation and the prescribed safeguards; consent alone creates no right to testing. In Amlesh Kumar v State of Bihar, the Supreme Court held that an accused has no indefeasible right to narcoanalysis, and that the court must weigh voluntariness, the safeguards and the totality of circumstances before authorising it. A subject who genuinely and freely agrees is not being made a witness against themselves, but that agreement does not by itself entitle them to the test; a subject who is pressured, tricked or ordered is being made one.

Consent, however, does not turn the product of the test into free evidence. Even a result obtained voluntarily, and any information later discovered by following up on that result, are governed by the National Human Rights Commission Guidelines of **2000**. Two things follow. First, a voluntary result is not automatically admissible as substantive proof of guilt merely because the subject agreed to the test; its use is constrained by the safeguards that framework imposes. Second, and less obviously, the protection does not reach the derivative material. A fact or physical object subsequently discovered with the help of a voluntary test may be proved under

section 27 of the Evidence Act, the discovery rule, so that although the voluntary result is not itself admissible against the subject, the physical evidence or fresh lead it throws up can be admitted against them. Stating the consent rule without this second half is the commonest way it is misremembered.

20(3)	21	2000
SELF-INCRIMINATION BAR	LIFE AND DIGNITY	NHRC GUIDELINES

TRAP **Reading the leading judgment as a total ban on these techniques.** It is not. What was struck down is the compulsory, involuntary administration of narcoanalysis, the polygraph and brain mapping; the voluntary, consented route survives, subject to the National Human Rights Commission safeguards. A candidate who writes that the tests are simply "banned in India" has stated the law too widely and thrown away the distinction the question is built to test. The accurate sentence names compulsion as the thing prohibited, and consent as necessary but not by itself sufficient: a voluntary request still needs judicial consideration and authorisation before it may proceed.

PITFALL

Conducting or lending clinical cover to one of these tests without valid, documented consent, on the assumption that an investigator's request or a court's involvement supplies the authority. It does not. What the law requires is the subject's own free consent, and its absence makes the administration unconstitutional however the request was routed. A psychiatrist asked to perform or supervise such a test should confirm consent independently, record it, and decline where consent is absent or coerced.

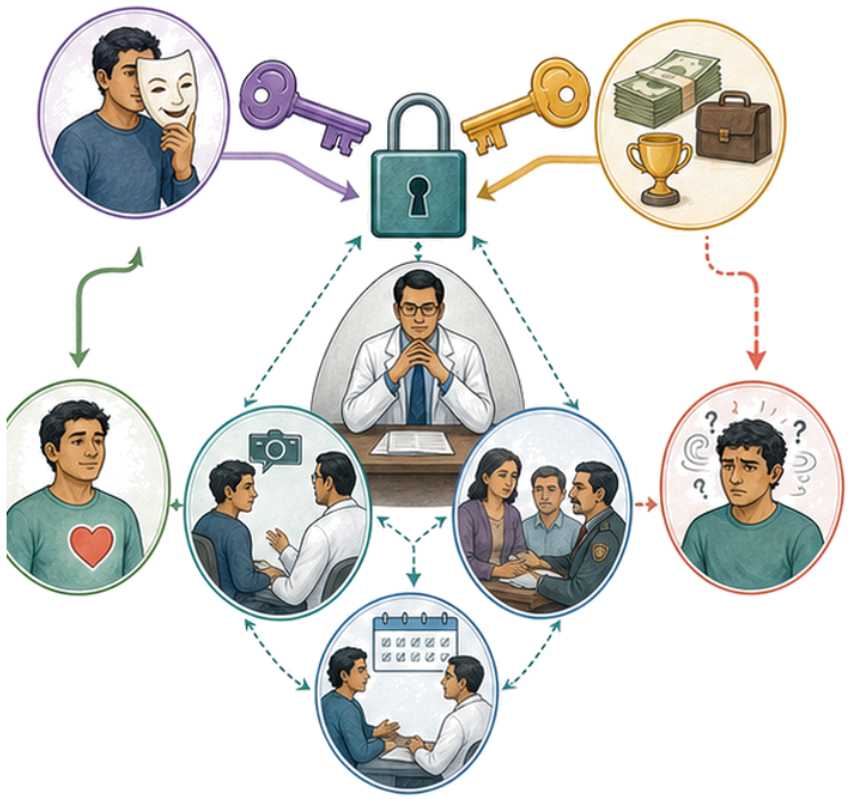
26.5 The psychiatrist's role and its limits

The clinician drawn into this area, whether asked to administer a test, to be present during one, or to interpret its result, works within tight boundaries. The first is scientific: the result is not a diagnosis and not a determination of truth, and it must never be presented to an investigator or a court as if it settled whether the subject is lying. At most it is one indirect and disputed datum. The second is legal: the psychiatrist cannot supply the consent the subject has not given, and no institutional request substitutes for it. The third is a matter of role, because the psychiatrist here is acting for the justice system rather than treating a patient, and the duties that flow from that shift - disclosure, the limits of confidentiality, the form of the eventual report - are the province of the Forensic ethics, consent and legal procedure notes and are not resolved by clinical instinct.

Kept in its place, the topic is straightforward. The examiner wants a candidate who separates three questions and answers each on its own terms: does the technique measure what it claims, which is doubtful; is its output reliable enough to act on, which it is not without independent corroboration; and may it lawfully be used, which it may, but only with consent and within the National Human Rights Commission framework. Confusing the three - treating a legal permission as a scientific endorsement, or a scientific criticism as a legal prohibition - is the very error the whole topic is constructed to expose.

GOOD TO REMEMBER

Before going near any of these tests, confirm and document the subject's own consent, and treat its absence as a bar rather than an obstacle to be worked around. Never present the output as a diagnosis or as proof that the subject is truthful or lying; confine any report to what was observed and defer the truth-question to the court. If asked to rely on a result, say plainly that it corroborates nothing on its own and would need independent verification to carry any weight.



IN INDIA

The Indian position is settled and practical. Brain mapping in its Brain Electrical Activation Profile form, together with narcoanalysis and the polygraph, is still sought at the investigation stage, but none of the three has independent evidentiary value, and consent alone creates no right to testing: a voluntary request remains subject to judicial consideration and authorisation, and for an accused seeking the test the appropriate stage is ordinarily when defence evidence is led at trial, not an automatic consent-based investigation-stage route (Amlesh Kumar v State of Bihar). Voluntary results and anything derived from them are handled under the National Human Rights Commission Guidelines, so a psychiatrist asked to conduct or interpret a test should treat consent as the threshold question and the guidelines as the operating limit, and should resist any suggestion that a test result can stand in for evidence a court would otherwise require.

No deception-detection test may be conducted without the subject's consent; compelling narcoanalysis, the polygraph or brain mapping violates the right against self-incrimination and amounts to cruel, inhuman or degrading treatment.

27 · Malingering and detection in forensic settings

Why the marks are here. A forensic opinion is only as good as the honesty of the person being examined, and in exactly the settings where a psychiatric report carries the most weight - a criminal charge, a compensation claim, a plea that the accused is too unwell to be tried - the examinee has the clearest possible reason to shape what the examiner sees. **Malingering** is the deliberate manufacture of illness for a payoff that lies outside the illness itself, and the psychiatrist who cannot recognise it is left in one of two failing positions: deceived into a false opinion, or, having learned to distrust, so quick to see feigning that the genuinely ill are disbelieved. The topic is examined because it sits at the precise point where clinical skill meets medico-legal consequence, and because the discriminations it demands - conscious from unconscious, external reward from internal need - are the ones candidates most often blur.

- Intentional production
- External incentive
- Look for inconsistency
- Use collateral evidence
- Do not diagnose from suspicion alone

Fig 25.12 Malingering requires both intentional production or gross exaggeration of symptoms and an external incentive. Detection integrates observed inconsistencies, collateral records and structured assessment; suspicion alone is not a diagnosis.

The single organising idea is that malingering is defined by two things at once: the symptom is produced or grossly amplified on purpose, and the reason for producing it lies outside the person, in some tangible gain the illness is meant to secure. Take away either half and it is no longer malingering. That double test is what separates it from every neighbouring presentation, and it is also what tells the examiner where to look, because a motive that is external and instrumental tends to leave external and instrumental traces.

> Malingering is the intentional production or gross exaggeration of symptoms for an external incentive; it is not a mental disorder but a condition warranting clinical attention, and it is established by positive, converging evidence of feigning, never inferred from an unwelcome diagnosis alone.

2	3	4
HINGE QUESTIONS	THE DIFFERENTIAL	EVIDENCE FAMILIES

27.1 What malingering is, and why it is not a diagnosis

To malinger is to feign. The examinee either produces a symptom that is not there or takes a real complaint and pushes it into **gross exaggeration**, and does so knowingly, in the service of a goal that the sickness is only a means to reach. The goals are worldly and specific: escaping a criminal trial or its punishment, evading a duty such as work or service, or securing money through a compensation or disability claim. This is what is meant by an **external incentive**. The reward is a change in the person's outward circumstances, not anything internal to their psychology, and it is the externality of the motive that gives the concept its shape and its detectability.

It follows from this that malingering is classified not as an illness but as a **condition warranting clinical attention**, something that may become the focus of an assessment without itself being a disorder with its own psychopathology, course and treatment. The distinction is not pedantry. A disorder is something the patient has and the clinician treats; malingering is something a person does and the clinician must detect and describe. Recording it in a report is therefore an assertion about conduct and motive, not about pathology, and it must be justified by evidence of the same order that any serious accusation demands. The examiner who forgets this drifts into using the word as a term of disbelief rather than as a finding, which is where reports go wrong.

27.2 The three-way differential: two questions that sort it

The heart of the topic is a differential across three presentations, and it resolves cleanly if two questions are asked in order. First, is the symptom produced deliberately, or does it arise outside the person's conscious control. Second, if it is deliberate, what is the incentive - something tangible in the outside world, or the internal satisfaction of occupying the role of a patient. The three presentations answer these two questions in three different combinations, and the combination is the diagnosis.

Malingering answers both: deliberate, for an external reward. **Factitious disorder** shares the first answer but not the second - the symptoms are produced deliberately, yet the motive is internal, the psychological need to be seen and treated as sick, what is classically called **the sick role**, with no external payoff in view. **Conversion** and the other unconsciously produced presentations answer the first question differently altogether: the symptom is genuine to the person and not deliberately made, so no question of incentive in the malingering sense even arises. The examiner who collapses these three - who calls a factitious patient a malingerer, or treats a conversion symptom as feigned - has made the single commonest error in the area, and it is an error about the two questions, not about the symptoms themselves.

AXIS	MALINGERING	FACTITIOUS DISORDER	CONVERSION AND OTHER UNCONSCIOUS PRESENTATIONS
How the symptom is produced	Deliberately produced or grossly exaggerated	Deliberately produced	Not deliberate; outside conscious control
The incentive behind it	External and tangible: escape trial or duty, gain compensation	Internal: to occupy the sick role	No conscious incentive; the symptom is experienced as real
Standing as a disorder	Not a disorder; a condition warranting clinical attention	A recognised mental disorder	A recognised mental disorder
The clinician's task	Detect the feigning and describe the evidence	Diagnose and manage the disorder	Diagnose and treat the disorder

MNEMONIC

Conscious for a prize, malinger; conscious for the role, factitious; not conscious at all, conversion

The two hinge questions compressed into one line. Deliberate production plus an external, tangible reward is malingering; deliberate production for the internal reward of the sick role is factitious disorder; a symptom that is not deliberately produced at all is conversion or another unconsciously generated presentation. Fix the awareness and the incentive, and the label follows.

TRAP **Equating malingering with factitious disorder because both involve deliberate symptoms.** The two part on the incentive, and its direction is the whole point: malingering runs on an external, tangible gain, factitious disorder on the internal need to be a patient. A candidate who defines malingering as "producing symptoms deliberately" and stops there has described both conditions and distinguished neither. The examiner is testing whether you can name the external incentive as the discriminator, so make that the sentence you write first.

27.3 Detecting malingering: converging evidence, not a single sign

Because the motive is external, the feigning tends to leave marks that honest illness does not, and detection is the disciplined business of looking for them and requiring several to point the same way before any conclusion is drawn. No single finding is proof, and the strength of the method lies entirely in convergence: one anomaly raises a question, several independent anomalies pointing at the same feigned presentation begin to answer it. Four families of evidence carry most of the weight, and it helps to understand why each one works and where each one fails.

- **Inconsistency between reported and observed function.** The examinee describes a level of impairment that their spontaneous behaviour, when they are not being formally tested, does not support: a memory said to be gone that works when the person is distracted, a weakness that eases when attention moves elsewhere, a distress that lifts in the waiting room. It works because sustaining a fabricated deficit across every unguarded moment is hard; it fails when the genuine condition itself fluctuates, so the gap must be marked, not fleeting.

- **Symptom patterns that are atypical or over-endorsed.** The feigned picture tends not to follow the natural shape of the disorder it imitates. Symptoms are affirmed too readily and too broadly, rare and improbable complaints are endorsed, and the presentation is often a lay caricature of illness rather than its true form. It works because a person mimicking a disorder cannot know its fine internal grammar; it fails where the examinee has real clinical knowledge or genuine partial illness that lends the account authenticity.
- **Poor effort on validity testing.** Structured tasks can be built so that even a severely impaired but honest person performs well, so that failure below that floor points away from illness and toward withheld effort. It works because it separates capacity from cooperation; it fails when it is over-read, since a single poor score in a distressed or poorly engaged examinee is a question, not a verdict.
- **Corroboration from collateral sources.** Records, informants and observation across time and across settings test the self-report against something the examinee does not control. It works because the story a person tells and the record others keep are hard to align if the story is invented; it fails only when collateral is thin, which is precisely when the examiner must say so rather than fill the gap.

RULE **Malingering is established by positive, converging evidence of feigning, never by exclusion and never from one sign.** A single failed test, an unlikeable examinee, or a diagnosis the person happens to want are not grounds; what is required is several independent lines - inconsistency, atypicality, poor effort and collateral - agreeing that the presentation is manufactured for a gain. Treating malingering as a diagnosis of exclusion, reached when nothing else seems to fit, inverts the logic and is how the genuinely ill come to be wrongly disbelieved.

27.4 Validity testing and the instrumental methods

Two kinds of structured testing formalise the effort question, and the exam rewards knowing that they ask different things. One asks whether the person is over-reporting symptoms, endorsing more, and more improbable, complaints than any real syndrome generates; this is the logic of **validity testing** applied to what the examinee says. The other asks whether the person is genuinely trying on a cognitive task, typically through forced-choice formats where even severe honest impairment leaves performance near the level that chance alone would give. Performing consistently below that level is a powerful single indicator, because doing worse than random guessing implies the examinee knew the correct answer and steered away from it, an effort that only a person controlling their own responses could produce.

AXIS	SYMPTOM VALIDITY: OVER-REPORTING	PERFORMANCE VALIDITY: POOR EFFORT
What it asks	Is the person reporting more, and more improbable, symptoms than a real syndrome produces	Is the person genuinely trying on the task
What flags feigning	Atypical, rare and over-endorsed symptoms	Effort below what severe genuine impairment or chance would give
What genuine illness looks like	A coherent pattern that fits the disorder's natural shape	Impairment that still shows real, sustained effort

Beyond the interview and these tests lie the instrumental methods of deception detection - narcoanalysis, brain mapping and the polygraph. They belong to the malingering conversation because they too claim to separate truthful from feigned or concealed report, but their reliability and, above all, their legal admissibility are contested, and that question is set out elsewhere in this chapter, where narcoanalysis, brain mapping and the polygraph are discussed. The malingering examiner should know these methods exist, should treat a positive instrumental result as neither necessary nor sufficient to establish feigning, and should defer the question of when they may lawfully be used to that discussion. The distinct ethical problem of subjecting an unwilling examinee to a procedure designed to catch them out belongs to the Forensic ethics, consent and legal procedure notes and is not settled here.

IN INDIA

The Indian settings that generate external incentives are the ones that generate malingering: criminal referrals in which an accused may feign illness to claim the unsound-mind exception or to be found unfit to plead, both of which are taken up elsewhere in this chapter, and compensation, disability and fitness-to-work assessments in which a certificate carries money or a livelihood. Well-standardised symptom and performance measures are often not to hand in routine practice, so the Indian assessment leans hardest on the two tools that are always available - careful documentation of observed against reported function, and collateral gathered from records and informants. The instrumental methods sometimes pressed for by investigating agencies sit under a contested legal position covered elsewhere in this chapter, and a psychiatrist asked to rely on them should keep that limit clearly in view.

27.5 The forensic assessment and its dangers

How the examination is actually conducted. Because the whole question is whether a self-report can be trusted, the assessment is built to test consistency rather than to take the account at face value. The examiner moves from open, unstructured enquiry to specific probing, re-examines the same ground at different times to see whether the story holds, and observes the examinee outside the formal interview where the effort of maintaining a fabricated deficit relaxes. Collateral is gathered before the interview, not after, so that the account can be checked against something independent while the person is still in the room. Throughout, the stance is neutral: malingering

is detected and documented, not confronted, because an accusation across the desk yields defensiveness and loses the observational advantage without adding evidence.

The hardest discipline is to hold two truths together. A person can be both malingering and genuinely ill, so a finding that some symptoms are exaggerated does not establish that the person is well, and detecting feigning never closes the separate question of real illness underneath it. Feigning is also a matter of degree rather than a switch, ranging from mild embellishment of a real complaint to wholesale fabrication, and the report should say where on that range the evidence places the presentation. What the psychiatrist supplies is a description of the evidence and the reasoning from it to a conclusion, framed as an inference of a stated strength; the report certifies findings, not a motive it cannot evidence, and the conventions for putting such an opinion before a court belong to the Forensic ethics, consent and legal procedure notes.

GOOD TO REMEMBER

Gather the collateral before you interview, not after, so the account can be tested against something independent while the person is in front of you. Keep the stance neutral, because malingering is detected rather than confronted, and hold on to the fact that feigning and genuine illness coexist, so exaggeration in part never proves wellness in whole. Describe the observed against the reported, let the convergence carry the weight, and where the evidence supports only doubt, write doubt and name what further information would settle it.

PITFALL

Committing the word "malingerer" to a medical record or a court report on an impression rather than on convergent evidence. The label is an accusation of deliberate fraud; asserted without the positive findings to support it, it is clinically wrong, because it forecloses a genuine illness that may coexist, and medico-legally reckless, because the opposing side needs only to show that the conclusion rested on suspicion for the whole report to fall. If the evidence supports only doubt, record doubt; a defensible report never reaches further than its findings allow.

28 · Psychiatric aspects of homicide and filicide

Why the marks are here. Killing is the point at which psychiatry and the criminal law meet most sharply, and the questions a court then puts to the psychiatrist - was this person responsible, what drove the act, could it have been foreseen and prevented - all turn on the mental state at the moment of the offence. **Filicide**, the killing of a child by a parent, concentrates these questions further, because it forces the assessor to hold together parental psychopathology, the safety of any surviving children and a society that finds the act almost unthinkable. This topic is examined less for its epidemiology than for two things a candidate must produce cleanly: the recognised classification of these killings, and the specific clinical contexts in which the risk is real.

The foundation is a base-rate fact that must be stated with care, because getting it wrong in either direction is a failure of both scholarship and fairness. Homicide committed by a person with mental illness is uncommon, and the great majority of people with even severe mental illness are never violent. What raises the risk is not the diagnostic label but the active symptomatic state:

lethal violence is over-represented in florid psychosis carrying persecutory or command features, and in acute substance intoxication. Holding both halves of that sentence together - the rarity and the specific high-risk state - is what separates a defensible answer from a stigmatising one.

Homicide by a person with mental illness is uncommon but is over-represented in active psychosis with persecutory or command features and in substance intoxication; filicide is classified by the parent's motive, neonaticide is a separate category tied to concealed pregnancy in a young mother, and postpartum psychosis is a recognised high-risk context for infanticide.

5	first day
RESNICK FILICIDE MOTIVES	NEONATICIDE WINDOW

28.1 Homicide in the context of major mental illness

The link between psychosis and homicide is real but narrow, and understanding its shape prevents both complacency and over-prediction. Risk rises when psychotic symptoms directly engage a potential victim: a **persecutory** delusional system that casts a specific person as a lethal threat, or hallucinations that **command** the patient to act, convert a private illness into a danger to others. The mechanism is one of subjective self-defence or of felt compulsion: the patient acts not on ordinary motive but within a delusional reality in which the act feels necessary or unavoidable. Substance intoxication is the second and independent amplifier - it disinhibits, distorts perception, and in combination with psychosis is a far stronger driver than either state alone.

The features that should raise concern in an acutely psychotic patient are worth holding as a short set:

- persecutory delusions that name or locate a specific persecutor, rather than a diffuse sense of threat;
- command hallucinations to harm, particularly where the patient shows early compliance or feels unable to resist them;
- delusions of passivity or control, in which the patient experiences their own actions as imposed from outside;
- comorbid substance intoxication, which lowers the threshold for acting on any of the above.

These are state markers, not a general risk formulation. The systematic taxonomy of static and dynamic risk factors, and the structured tools that weigh them, are developed elsewhere in this chapter; the point here is narrower - that lethal violence in mental illness is bound to the active symptomatic state, which is why it is often reversible with treatment and why the assessment of any homicide case begins with a disciplined reconstruction of the mental state at the time of the act. Where that reconstruction establishes that the act arose from an illness meeting the legal threshold, the matter becomes one of criminal responsibility, the insanity defence, taken up in full elsewhere in this chapter; short of that threshold, India has no diminished-responsibility

defence, so the mental abnormality may instead bear on proof of an offence-specific mental element or on sentence, or engage the grave-and-sudden-provocation exception where its own conditions are independently established, matters taken up in full elsewhere in this chapter.

28.2 Filicide and its classification by motive

Filicide is the killing of a child by a parent, and the single most examinable fact about it is that it is classified by the parent's motive, not by the method or the age of the child. The most widely used scheme is **Resnick**'s, which separates the killings into motivational groups. Learning them as motives rather than as a bare list is what makes them clinically useful, because the motive is what predicts the mental state behind the act and the way the law is likely to treat it.

In **altruistic** filicide the parent kills out of a distorted belief that death spares the child suffering - the severely depressed mother who can see no future for herself or her child, or the psychotic parent convinced the child is doomed. It is the category most strongly associated with serious affective or psychotic illness and with maternal suicide, the killing forming part of an extended suicide. **Acutely psychotic** filicide is killing driven directly by psychosis, by command hallucinations or delusions, without the coherent if deluded protective logic of the altruistic type; here the act may be bizarre and, in any ordinary sense, unmotivated. The **unwanted-child** type is the killing of a child the parent regards as an obstacle or a burden, classically where the child is genuinely unwanted and the parent unsupported. **Fatal maltreatment**, sometimes called accidental filicide, is death resulting from cumulative abuse or neglect rather than from an intention to kill, and it is the category that sits at the interface with child protection. The **spouse-revenge** type, the rarest, is the killing of a child in order to inflict suffering on the other parent.

RULE **Filicide is classified by the parent's motive, not by the act.** The same outcome, a dead child, can arise from profound depressive illness, from florid psychosis, from an unwanted pregnancy or from cumulative neglect, and it is the motive that fixes the likely mental state, the risk to any surviving children and the legal disposal. An answer that catalogues methods or injuries has missed the axis the examiner is testing.

RESNICK CATEGORY	CORE MOTIVE	TYPICAL MENTAL STATE	FORENSIC AND CLINICAL EMPHASIS
Altruistic	To spare the child suffering	Severe depression or psychosis; risk of extended suicide	Strongest link to major mental illness; assess the parent's own suicidality
Acutely psychotic	No rational motive; act driven by symptoms	Active psychosis, command hallucinations, delusions	Reconstruct the symptoms operating at the time of the act
Unwanted child	Child experienced as a burden or obstacle	Often no major mental illness; situational	Social adversity, support, and safeguarding of future children
Fatal maltreatment	No intent to kill; death from abuse or neglect	Variable; personality, substance use, stress	Interface with child protection and surviving siblings
Spouse revenge	To make the other parent suffer	Often personality pathology rather than psychosis	Rarest; focus on the parental relationship

28.3 Neonaticide as a distinct category

Neonaticide, the killing of a newborn within **the first day of life**, is commonly treated as a special, age-defined subtype of filicide, analysed separately because its perpetrator profile is different. It is classically committed by a young mother who has denied or concealed the pregnancy, often frightened, unsupported and without antenatal care, who delivers alone and disposes of the newborn in a state of panic or dissociation. Major mental illness is usually absent; what dominates is denial, immaturity and social desperation rather than psychosis or depression. Because both the psychopathology and the social setting differ so completely from the filicide motives, neonaticide is analysed on its own terms, and folding it into the motive list for older children is a standard and costly error.

TRAP **Neonaticide is a special, age-defined subtype of filicide, and it is not usually a mental-illness case.** Candidates absorb the first-day killing into the motive classification and reach for psychosis or depression to explain it. The prototypical picture is the opposite: a concealed pregnancy in a young, unsupported woman, a solitary delivery, and a dissociative or panic-driven act, with no major mental illness at all. The discriminator the examiner wants is the perpetrator profile, not a motive.

28.4 Postpartum psychosis and the risk of infanticide

Standing apart from both the situational neonaticide and the diverse filicide motives is the killing that arises out of **postpartum psychosis**, a recognised high-risk context for infanticide. Puerperal psychosis is a psychiatric emergency: it can arise abruptly in the early period after delivery, it is frequently affective in colour, and it can carry delusions concerning the infant - that the baby is defective, evil, or better off dead - together with command phenomena. The lethal danger is that these beliefs generate exactly the altruistic and acutely psychotic mechanisms described above, now directed at a wholly dependent newborn who cannot protect itself. This is

why the condition is treated as an emergency regardless of how settled the mother appears in the intervals between disturbance.

GOOD TO REMEMBER

A mother with postpartum psychosis should never be assumed safe to be the sole carer of her infant on the strength of a calm interview. Ask directly about intrusive or command-driven thoughts of harming the baby, arrange urgent review and admission, and keep mother and infant together only under supervision. The decision to admit jointly or to separate is a safeguarding decision as much as a treatment one.

Treatment is urgent, and where the illness is severe or life is at risk it may include physical treatments whose clinical technique and consent framework belong with the ECT and neurostimulation notes; the forensic point here is only that recognition and containment of the risk must come first.

28.5 The psychiatric assessment of the parent or perpetrator

What the psychiatrist actually does. The psychiatric contribution to a homicide or filicide case is a careful reconstruction of the mental state at the time of the act and a formulation of the motive, because these determine everything that follows: the availability of the insanity defence or a partial defence, the risk to any surviving children, and the treatment the perpetrator needs. The assessment gathers the person's account of the act, the pre-offence history and mental state, collateral and documentary evidence, and screens specifically for the depressive, psychotic and intoxication states that carry the risk. In a parent, it must always extend to the safety of other children in the household.

PITFALL

The dangerous clinical error is to hear a depressed mother say her children would be better off without her, or better off coming with her, as if it were ordinary depressive worthlessness. In a parent, the thought that a child would be better off dead is altruistic-filicide ideation until proven otherwise, and it must be asked about as directly and as specifically as suicidal ideation, with the same threshold for protective action. Missing it because it was heard as routine rumination is how a preventable death is not prevented.

IN INDIA

In Indian practice the evaluation of a mother who has killed her infant or newborn usually turns on reconstructing the perinatal mental state and screening for postpartum psychosis and severe depression, because the legal disposal runs through the general criminal law and the defences taken up elsewhere in this chapter. The classic neonaticide setting, a concealed pregnancy in a young and unsupported woman, is a recurring feature of casework, and it calls for a social and safeguarding response as much as a psychiatric one.

Two boundaries frame the work and should be named rather than absorbed. The formal examination for the court, the expert report, and the ethics of acting where treatment meets

evidence belong with the Forensic ethics, consent and legal procedure notes. Where fatal maltreatment or the safety of surviving children brings child-protection law into play, the governing statutes are set out in the Child psychiatry: assessment, treatment, services and protection notes. The forensic psychiatrist names these frames and works within them, but the assessment itself remains what it has always been: a disciplined reconstruction of a mind at the moment it did something almost unbearable to contemplate.

Civil law, capacity and family law

29 · Testamentary capacity (criteria and assessment)

Why the marks are here. A will speaks only after its maker is dead, at the one moment when the person who could explain it can no longer be asked, so the law insists that the mind behind it was sound when the document was made. Disputes about that soundness are common - a late will that cuts out one child, a large gift made in the shadow of dementia, a bequest a family says was the product of illness - and the court that must resolve them turns to the psychiatrist for an opinion on capacity. The examiner rewards the candidate who treats **testamentary capacity** as what it is: a functional, decision-specific and time-specific test, governed by a statute that says who may make a will and by a classic common-law authority that says what a sound mind for that particular purpose actually involves. A bare diagnosis is not the answer to any of it.

Two sources hold this topic together, and the disciplined answer keeps both in view at once. The Indian Succession Act supplies the statutory frame: it names who is competent to make a will and, through a short set of Explanations, tells us what soundness of mind means for this act and when it is measured. The common law supplies the anatomy of that soundness through the case every examiner expects by name, which breaks the "sound mind" of the statute into the concrete faculties a testator must actually exercise. Learn the two together and the wrong-statute traps that cluster around this topic fall away.

59	1925	1870	4
MAKING A WILL	INDIAN SUCCESSION ACT	BANKS V GOODFELLOW	LIMBS OF SOUNDNESS

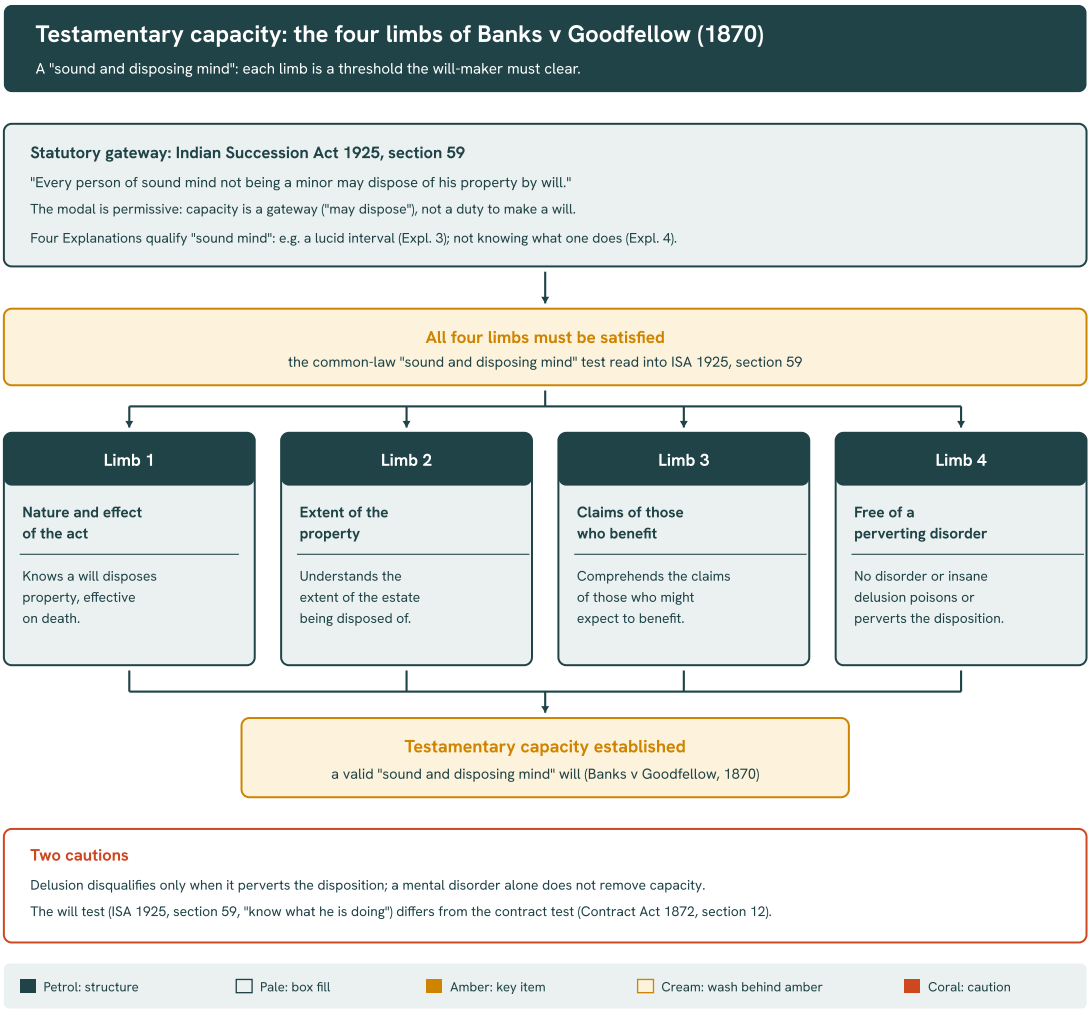


Fig 25.13. The four limbs of testamentary capacity from Banks v Goodfellow (1870), read into the permissive gateway of Indian Succession Act 1925, section 59. All four thresholds must be cleared for a "sound and disposing mind"; a mental disorder or delusion disqualifies only when it perverts the disposition.

29.1 Who may make a will

The starting provision sits in the Indian Succession Act of **1925**, at section **59**, and its opening words set both the standard and its character: every person of **sound mind** not being a minor may dispose of property by will. Two features of that sentence repay slowing down on. The first is that the operative verb is permissive - the section says such a person may make a will, conferring a power rather than imposing a duty. It is an enabling provision, naming who is free to dispose of their estate rather than commanding that anyone must. The second feature is that competence is stated as the pairing of two requirements, soundness of mind and majority, joined so that a sound-minded child cannot make a valid will and neither can an adult whose mind is not sound at the material time.

For the psychiatrist the majority limb is not our concern - age is a matter of record the court establishes for itself - and the whole clinical enquiry lives in the words "sound mind." That phrase is the hinge of the topic. It is not used in its loose everyday sense; the Act gives it content through

the Explanations that follow the main provision, and it is those Explanations, not a diagnostic label, that the examiner wants reproduced and applied.

29.2 What soundness of mind means for a will

The provision qualifies "sound mind" through **four** Explanations, and together they convert a vague adjective into a set of workable rules. The first preserves the will-making power of a married woman over any property she could dispose of by her own act during her life; it is a rule about legal personality rather than about psychiatry, and it does not turn on any mental state. The remaining Explanations are the ones that matter clinically, because each fixes a relationship between a mental state and the power to make a will.

The second Explanation is a caution against equating a sensory or communication impairment with incapacity: persons who are deaf or dumb or blind are not, on that account, incapacitated from making a will, provided they are able to know what they do by it. The condition attached is the whole of the rule: the impairment does not disqualify so long as the person can understand what the act of making the will achieves. The third Explanation is the one candidates most often reach for: a person who is ordinarily insane may make a valid will during an interval in which he is of sound mind, the **lucid interval** in which the standing illness has, for the time being, lifted. The rule is permissive and it is real: an established diagnosis of chronic mental illness does not bar a will made in a genuine window of clarity.

The fourth Explanation states the outer bound in the negative and in absolute terms: no person can make a will while he is in such a state of mind, whether arising from intoxication or from illness or from any other cause, that he does not know what he is doing. The modal force here is worth marking, because it is the mirror of the third: this is not a "may not" that admits of exception but a flat "cannot," and it is deliberately cause-neutral, reaching any state, however it is arrived at, that robs the person of knowing what the act of willing is. The through-line of those clinical Explanations is a single test seen in different situations - the will stands or falls on whether, at the moment of making it, the person knew what they were doing by it.

Held as a single picture, the four Explanations read as follows.

THE SITUATION	WHAT THE WILL-MAKING PROVISION SAYS
A married woman	May dispose by will of any property she could alienate by her own act during her life
A person who is deaf, dumb or blind	Is not thereby incapacitated, provided able to know what they do by the will
A person who is ordinarily insane	May make a will during an interval in which he is of sound mind - a lucid interval
Any person whose mind is disordered by intoxication, illness or any other cause	Cannot make a will while in a state in which he does not know what he is doing

29.3 The common-law test: a sound and disposing mind

The statute tells us that soundness is required and, through the third and fourth Explanations, that it is judged at the moment of making the will, but it does not itself spell out the faculties that soundness comprises. That anatomy comes from the common law, from **Banks v Goodfellow** of **1870**, in which Cockburn CJ set out the test of the **sound and disposing mind** that Indian courts continue to apply. The judgment identifies **four** things a testator must be able to do. The testator must understand the nature of the act of making a will and its effects - that this document directs who will take the estate after death. The testator must understand the extent of the property being disposed of, in broad terms rather than to the last rupee. The testator must be able to comprehend and appreciate the claims of those who might expect to benefit, the persons who have a natural call on the testator's bounty, whether or not the testator chooses in the end to provide for them. And, negatively, no disorder of the mind must poison the affections or pervert the sense of what is right so as to distort the disposition itself.

The understanding limbs are cognitive and specific to the act of testation: they ask what the person can grasp and weigh about this will, this estate and these potential beneficiaries. The final limb is different in kind. It is not a further thing to understand but a negative condition, a requirement that no mental disorder reach into and distort the very choices those limbs describe. That structure is why the test can be satisfied by a person who is far from mentally well, and can fail in one whose cognition on formal testing looks intact: the four limbs ask not whether the mind is healthy but whether it was, for this act, sound and disposing.

MNEMONIC

Deed, Extent, Claims, Delusion

The four limbs of the sound and disposing mind, in order: understand the **Deed** - the nature of making a will and its effect; grasp the **Extent** of the property being given; comprehend and appreciate the **Claims** of those who might expect to benefit; and be free of any disorder or delusion that perverts the disposition. The understanding limbs are faculties the testator must have; the delusion limb is a distortion they must not have.

RULE **A valid will needs a sound and disposing mind at the moment of execution.** The statute sets the standard - soundness of mind together with majority - and the common-law test unpacks soundness into the four faculties the testator must exercise: understanding the act and its effect, the extent of the estate, and the claims of those who might benefit, with no disorder of the mind perverting the disposition. It is a capacity for this decision at this time, not a global verdict on the person or a certificate of mental health.

29.4 Disorder, delusion and the survival of capacity

Capacity survives a diagnosis. The single most discriminating feature of the test lives in its fourth limb, and it runs against intuition. A testator may carry a serious mental disorder, and may even hold frank delusions, and still have testamentary capacity; the presence of illness does not, by itself, defeat the will. What defeats it is narrower and more specific: an **insane delusion** counts only when it is one that influences the disposition, poisoning the testator's natural affections or

their sense of who has a claim, and so bringing about a gift that a sound mind would not have made.

The distinction is best held with a pair of examples. A testator who harbours a fixed, unfounded belief about some matter wholly unconnected with the estate - a delusion about a neighbour, or about events long past - may still make a perfectly valid will, because that belief plays no part in how the property is divided. Contrast the testator who believes, against all reason and evidence, that a devoted child is an enemy conspiring against them, and who disinherits that child precisely for that reason: here the delusion has reached into the disposition and perverted it, and capacity fails. The question the assessor must answer is therefore not "is this person deluded" but "did a delusion shape this will," and only the second defeats it. This is why testamentary capacity can be partial and disposition-specific rather than all-or-nothing.

None of this is a historical curiosity. The sound-and-disposing-mind test remains the governing common-law standard for testamentary capacity, applied and reaffirmed in modern probate litigation, including the recent English authority of **Hughes v Pritchard** - the live framework the assessment must be built around, not a nineteenth-century relic to be recited and set aside.

TRAP **Assuming that a mental disorder, or a delusion, automatically destroys testamentary capacity.** It does not. A testator may have a diagnosis, or even hold delusions, and still make a valid will; capacity fails only where a delusion actually influences the disposition. Writing that the testator "was psychotic and therefore lacked capacity" answers the wrong question and loses the mark, because the examiner is looking for the causal link between the delusion and the terms of the gift, not the mere co-existence of illness and a will.

Testamentary capacity is decision-specific and time-specific: a valid will needs a sound and disposing mind at the moment of execution - the testator understanding the act, the extent of the estate and the claims upon it - and a mental disorder defeats it only when a delusion actually perverts the disposition.

29.5 Assessing and recording testamentary capacity

Because the test is functional and fixed to a moment, the assessment must be functional and, very often, retrospective. Two quite different referrals arise. In the contemporaneous referral the psychiatrist assesses a living testator - typically elderly or seriously ill - at or near the time the will is made, so that a record of capacity exists should it later be contested. In the retrospective referral, the commoner one, the testator has died and the mental state at execution must be reconstructed from whatever survives: the clinical record, the notes of the person who took instructions and prepared the will, informant accounts of the testator's conduct at the time, and the terms of the will itself. In neither case is the task to certify a diagnosis or to pronounce the person globally capable or incapable; it is to map the limbs of the test onto this particular will.

In practice the enquiry tracks the limbs of the test:

- Does the testator understand that they are making a will, and what a will does - that it directs who receives their property after death?

- Do they have a realistic grasp of the nature and extent of the property they are disposing of?
- Can they identify and weigh the claims of those who might expect to benefit, family and dependants, even where they choose in the end to exclude them?
- Is there a mental disorder present, and if so, is any delusion influencing the disposition, or is the illness irrelevant to the choices actually made?

Two habits separate a useful opinion from a dangerous one. The first is to record the testator's actual reasoning - the words in which they described the estate, named the family, and explained the exclusions - rather than a bare conclusion, so that the court can see how each limb was met or failed. The second is candour about the evidence: where the contemporaneous record is thin the psychiatrist should say so and frame the view as an inference, because an overstated report both misleads the court and destroys the witness's credibility under challenge. Good practice, though not a statutory command, is to arrange a capacity assessment whenever an aged or gravely ill person makes a will. The form in which the opinion is finally put before a court, the expert report and the certificate for the court, is not testamentary law and is treated in the Forensic ethics, consent and legal procedure notes.

GOOD TO REMEMBER

Assess and record the testator's grasp of three things against the actual will - the act of making it, the extent of the estate, and the claims of those with a call on their bounty - and ask specifically whether any delusion is shaping the gift. Where a testator is elderly or seriously ill, a capacity assessment made at the time the will is executed is worth far more than any reconstruction attempted after death, once memory has hardened into partisanship.

IN INDIA

Wills are governed by the Indian Succession Act, and its provision on who may make a will supplies the statutory soundness standard that the courts read together with the Banks v Goodfellow limbs. The psychiatrist advises and the court decides, since testamentary capacity is ultimately a finding of fact for the judge. In everyday practice the referral is civil and usually retrospective, arising from a contested will, and the useful report is the one that tracks the limbs of the test against the particular will and testator rather than offering a diagnosis or a blanket judgement on the deceased.

29.6 Keeping the will test apart from its neighbours

Testamentary capacity is one of a family of legal capacities, each with its own standard and its own governing text, and the examiner's favourite move is to run them together. The capacity to make a binding agreement - contractual capacity - is governed by its own provision in the Indian Contract Act, with its own definition of soundness of mind, and it is taken up as its own topic in this chapter; its test is not the will test and must not be borrowed for one. The capacity to make a mental-healthcare or treatment decision has its own statutory test under the Mental Healthcare Act and is likewise treated elsewhere in this chapter. What these capacities share is a common structure, not a common test: each is decision-specific and time-specific, so the assessor must first

identify which decision the law has actually raised, reach for the right standard, and apply that standard's own limbs.

India retains these as distinct, separately worded tests rather than a single all-purpose capacity, and for the careful examinee that is a help rather than a burden. The discipline is simply to pair the decision with its own test - a will with the sound and disposing mind, a contract with the contract-law definition of soundness, a treatment decision with the mental-health-law test - and never to answer one capacity question with another's wording or another's statute. The candidate who keeps the acts, the standards and the limbs paired loses nothing to the confusion the paper is built to induce.

PITFALL

Answering a will question with the wrong statutory test. Soundness of mind for a contract has its own definition in the Indian Contract Act, and it is not the standard for a will; a testator's capacity is measured against the Indian Succession Act's soundness requirement and the Banks v Goodfellow limbs, at the moment of execution. Lifting the contract-law soundness test - or a standing "of unsound mind" label from the case notes - across to a disputed will is a scope error that produces the wrong answer even when every clinical fact in the report is correct.

30 · Contractual capacity and competence

Why the marks are here. A psychiatrist is pulled into contract law the moment a family disputes a gift, a sale, a loan or an agreement signed by a relative who was, or is said to have been, mentally unwell. The court does not ask whether the person carried a diagnosis; it asks a narrower and far more answerable question - was this particular person, at the particular moment of the transaction, able to understand what they were doing and to judge its effect on their own interests. Contractual capacity is therefore a functional and time-bound test, and the examiner rewards the candidate who can name the governing sections precisely, reproduce their exact wording, and keep this test cleanly apart from the neighbouring tests of testamentary capacity and of capacity to make a treatment decision.

The whole topic sits in two short sections of one old statute, and the discipline the examiner is testing is statutory rather than clinical: can you say who the law treats as competent, what it means by soundness of mind, and at what instant that soundness is measured. Each of those is a separate provision with its own wording, and the difference between a discretionary "may" and a mandatory rule is exactly the kind of detail the paper is built to find. A candidate who paraphrases the gist loses marks a candidate who quotes the limbs keeps.

11	3	12	2
COMPETENCE	CUMULATIVE CONDITIONS	SOUND MIND	SOUNDNESS LIMBS

30.1 Who is competent to contract

The law of who may enter a binding agreement is set out in the Indian Contract Act of **1872**, at section **11**. It treats a person as **competent to contract** only when **three** conditions hold together, joined in the text by "and" and therefore strictly cumulative: the person is of the **age of**

majority according to the law to which they are subject; is of sound mind; and is not disqualified from contracting by any law to which they are subject. Because the conditions are cumulative, the failure of any single one defeats competence. A mentally sound adult who happens to be disqualified by some other statute is not competent, and neither is a mentally sound person who is below the age of majority.

The age limb is why a minor cannot bind themselves. An agreement made by a minor is not merely unenforceable against them; it is **void ab initio**, void from the very beginning, the position long settled in the **Mohori Bibee** line of authority. This void-from-the-outset position is settled for a minor's agreement specifically, and it should not be read across to the other two limbs as though incompetence from any source produced the identical result. The consequence of an agreement made by a person who was not of sound mind is left to the statutory provisions taken up below and is not asserted here.

The third limb, that the person is not disqualified by any other law, is a reminder that soundness of mind is only one of the doors that must be open. Various statutes disqualify particular persons or particular kinds of transaction, and where they bite, competence fails regardless of how lucid the person was. For the psychiatrist this is a useful boundary: the remit is the sound-mind limb, and it is neither necessary nor appropriate to opine on age or on legal disqualifications, which the court establishes for itself. The clinical question is confined to the one limb the law actually refers to a mental state.

MNEMONIC

Age, Mind, No-bar

The three cumulative requirements of the competence section, in order: **Age** of majority, sound **Mind**, and **No** legal **bar** - not disqualified from contracting by any law to which the person is subject. All three must hold at once; the failure of any one defeats competence.

30.2 What "sound mind" means for a contract

Soundness of mind is not left to ordinary usage; it is given its own definition, for this purpose alone, at section **12**, and this is the provision the psychiatrist is really being asked about. A person is of **sound mind** for the purpose of making a contract if, at the time of making it, they are capable of two things together: understanding the contract, and forming a **rational judgement** as to its effect upon their interests. The test therefore has **two** limbs - comprehension of the transaction, and rational appraisal of what it will do to one's own position - and both must be present for the mind to count as sound.

The two limbs are worth pulling apart, because they fail in different ways. The first is cognitive and specific to the deal: does the person grasp the nature and the terms of this transaction, what is being given and what is being received. The second is evaluative and self-referential: can the person weigh the consequences of the bargain against their own interests, seeing that a sale below value depletes their estate, or that standing surety exposes them to another's debt. A person may

understand the mechanics of a contract in the abstract and still be unable, through illness, to appraise its effect on themselves; it is the pairing of the two capacities that the section demands.

A functional test, not a diagnostic one. Nothing in this definition turns on a label. A person may carry a serious psychiatric diagnosis and still satisfy both limbs for a given transaction, and a person with no diagnosis at all may fail them in a state of acute confusion. The statute asks what the mind could do at the moment, not what condition it bears. This is why a bare certificate that the person "suffers from a mental illness" answers the wrong question: the court needs to know whether, for this transaction, the person could understand it and reason about its effect on their own interests, which a diagnosis alone can neither establish nor exclude.

RULE **A contract needs a competent mind at the moment it is made.** Competence is the cumulative package of the competence section - majority, sound mind, and no disqualification - and soundness of mind for this purpose is the capacity, at the time of contracting, to understand the agreement and to form a rational judgement of its effect on one's own interests. Both the standard and the timing are set by statute, not by the assessor's general impression of the person.

30.3 Soundness is judged at the moment of contracting

The most examined feature of the definition is its timing. Soundness is assessed at the instant the contract is made, not as a standing trait, and the statute spells out what that means through two situational rules that cut in opposite directions. A person who is usually of unsound mind, but occasionally of sound mind, may make a contract when they are of sound mind: the recognised illustration is the **lucid interval**, in which an otherwise incapacitated person contracts validly during a genuine window of clarity. The mirror rule is stricter and is the one candidates forget: a person who is usually of sound mind, but occasionally of unsound mind, may not make a contract while they are of unsound mind, so the ordinarily capable person who signs while delirious or intoxicated is, for that transaction, outside the section's protection.

The reason the section is built this way is evidential as much as conceptual. If capacity can flicker, then what governs a disputed deal is the mental state at the material time, and contemporaneous evidence of that state - the notes of the day, the observations of those present, the person's own conduct around the transaction - becomes decisive. Conditions that wax and wane, such as delirium or intoxication, make the timing the whole question, because the same person may be within the section one hour and outside it the next. The two rules together say that neither a usual incapacity nor a usual capacity settles the matter; only the state at the moment does.

The two situational rules are best held as a single picture, since a candidate who remembers one half routinely forgets that it works both ways.

USUAL BASELINE	STATE AT THE MOMENT OF CONTRACTING	EFFECT ON THIS CONTRACT
Usually of unsound mind, occasionally sound	Sound - a genuine lucid interval	May make the contract
Usually of sound mind, occasionally unsound	Unsound - for example delirium or intoxication	May not make the contract

Contractual capacity is transaction-specific and time-specific: the only question is whether, at the moment of the deal, the person could understand it and form a rational judgement of its effect on their own interests.

30.4 Assessing and reporting contractual soundness

Because the statutory test is functional and tied to a moment, the assessment must be functional and, very often, retrospective. By the time a dispute reaches a psychiatrist the transaction is usually months or years past, so the opinion is reconstructed from contemporaneous records, the person's own account, informant histories, and any independent evidence of the mental state around the material time. The psychiatrist is not certifying a diagnosis and is not declaring the person globally capable or incapable; the task is to map the two statutory limbs onto the specific agreement in question, and to say, as far as the evidence allows, whether they were met when it was signed.

In practice the enquiry follows the section's own structure:

- Did the person understand the nature of this transaction - what was being given, received or promised, and on what terms?
- Could they form a rational judgement as to its effect on their own interests, weighing the benefit against the cost or the risk?
- Was that capacity present at the time the contract was made, allowing for fluctuation and for genuine lucid intervals?
- Is the opinion documented with the person's actual reasoning, rather than a bare conclusion, so that a court can see how each limb was met or failed?

The honest retrospective opinion is careful about its own limits. Where the contemporaneous record is thin, the psychiatrist should say so and frame the view as an inference rather than a certainty, because the burden of persuading the court sits with the party challenging the transaction and an overstated report does that party's work while damaging the witness's credibility. The manner in which the opinion is finally put before a court - the form of the report, the psychiatrist's duties as an expert, and the certificate for the court - is not contract law and is treated in the Forensic ethics, consent and legal procedure notes; here the point is only that the clinical content of the opinion is dictated by the two statutory limbs and by the moment at which they must be shown.

GOOD TO REMEMBER

Assess and record the person's understanding of the particular deal and their reasoning about its effect on their own interests, at the material time. A global label - "of unsound mind" - is not what the court can act on; the demonstrated grasp of this transaction is. Where the records will not support a firm view, say the evidence is insufficient rather than filling the gap with an impression.

IN INDIA

The governing standard is statutory: the Indian Contract Act fixes the definition of soundness, and the psychiatrist advises rather than decides, since competence is ultimately a finding for the court. In everyday practice the referral is civil and retrospective, arising from a contested gift, property transfer, sale or agreement, and the useful report is the one that tracks the two statutory limbs against the specific transaction rather than offering a diagnosis or a blanket verdict on the person.

30.5 Keeping the contracting test apart from its neighbours

Contractual soundness is one of a family of legal capacities, each with its own test, and the examiner's favourite error is to run them together. The capacity to make a valid will - testamentary capacity - is governed by a different provision, in the Indian Succession Act, and by a different standard; it is taken up as its own topic in this chapter and must not be answered with the contracting definition. The capacity to make a mental-healthcare or treatment decision has its own statutory test under the Mental Healthcare Act and is likewise treated elsewhere in this chapter. What these capacities share is a boundary rather than a common test: because each has its own statutory standard, the contracting definition cannot be lent to a will dispute or to a treatment-refusal question, and the psychiatrist must answer the exact capacity the court has actually raised.

India retains these as distinct, separately worded tests rather than a single all-purpose capacity, and that is a strength for the careful examinee: the discipline is simply to identify which act is in issue, reach for the right statute, and apply its limbs. The contracting test measures understanding and rational judgement of a bargain's effect on the maker's interests; a will and a treatment decision each ask something with its own wording and its own moment. The candidate who keeps the acts, the statutes and the limbs paired loses nothing to the confusion the paper is trying to induce.

TRAP **Answering a will or a treatment-refusal question with the contracting test.** The soundness-of-mind definition for contracting is a distinct statutory test. Testamentary capacity lives in the Indian Succession Act under its own standard, and treatment-decision capacity under the Mental Healthcare Act; quoting the contract definition for all three, or naming the wrong statute, is the classic way to lose an otherwise easy mark.

PITFALL

Treating a diagnosis as though it settled the matter. A standing diagnosis of mental illness, dementia or intellectual disability does not by itself void a contract, and a person may hold a serious diagnosis yet retain soundness for a particular deal, or regain it in a lucid interval. Reading soundness as a global, once-and-for-all status rather than a transaction-specific and time-specific finding is how a clinician's report overreaches what the statute actually asks - and it cuts the other way too, since an ordinarily well person can lose soundness for a transaction signed while acutely confused.

31 · Marriage, nullity and mental illness (Hindu Marriage Act, Special Marriage Act)

Where the marks sit. Mental capacity at the time of the marriage decides whether a ground for nullity exists, not whether the parties are married at all: a defect present at the wedding leaves the marriage standing until a court acts on it, and the governing Act decides whether that route is annulment of a voidable marriage or a declaration that the marriage was void. When mental illness is said to have been present at the moment the marriage was contracted, the question the court is really asking is one of formation - was this a good marriage in the first place - and the answer is nullity, not divorce. The psychiatrist is drawn in to speak to the state of a party's mind at the wedding, not at some later crisis, and the marks reward the candidate who keeps a formation defect apart from a dissolution ground and who can reproduce the exact statutory wording rather than gesture at its gist.

Two statutes carry this in the personal law a candidate must know. The Hindu Marriage Act governs marriages between Hindus, and the Special Marriage Act governs a civil, secular form of marriage irrespective of religion, subject to the section 4 conditions and the current law; each sets a mental-capacity condition for a valid marriage in near-identical words, but the two Acts part company on what a breach of it does to the marriage. Under the Hindu Marriage Act a breach makes the marriage voidable and open to annulment by a decree of nullity; under the Special Marriage Act the same breach makes the marriage void. The discipline the paper tests is statutory: the right section, the right limb, the right modal verb, and the clean line between void and voidable, which here runs between the two Acts themselves.

5	12	4	24
HINDU CONDITIONS	HINDU VOIDABLE	CIVIL CONDITIONS	CIVIL VOID

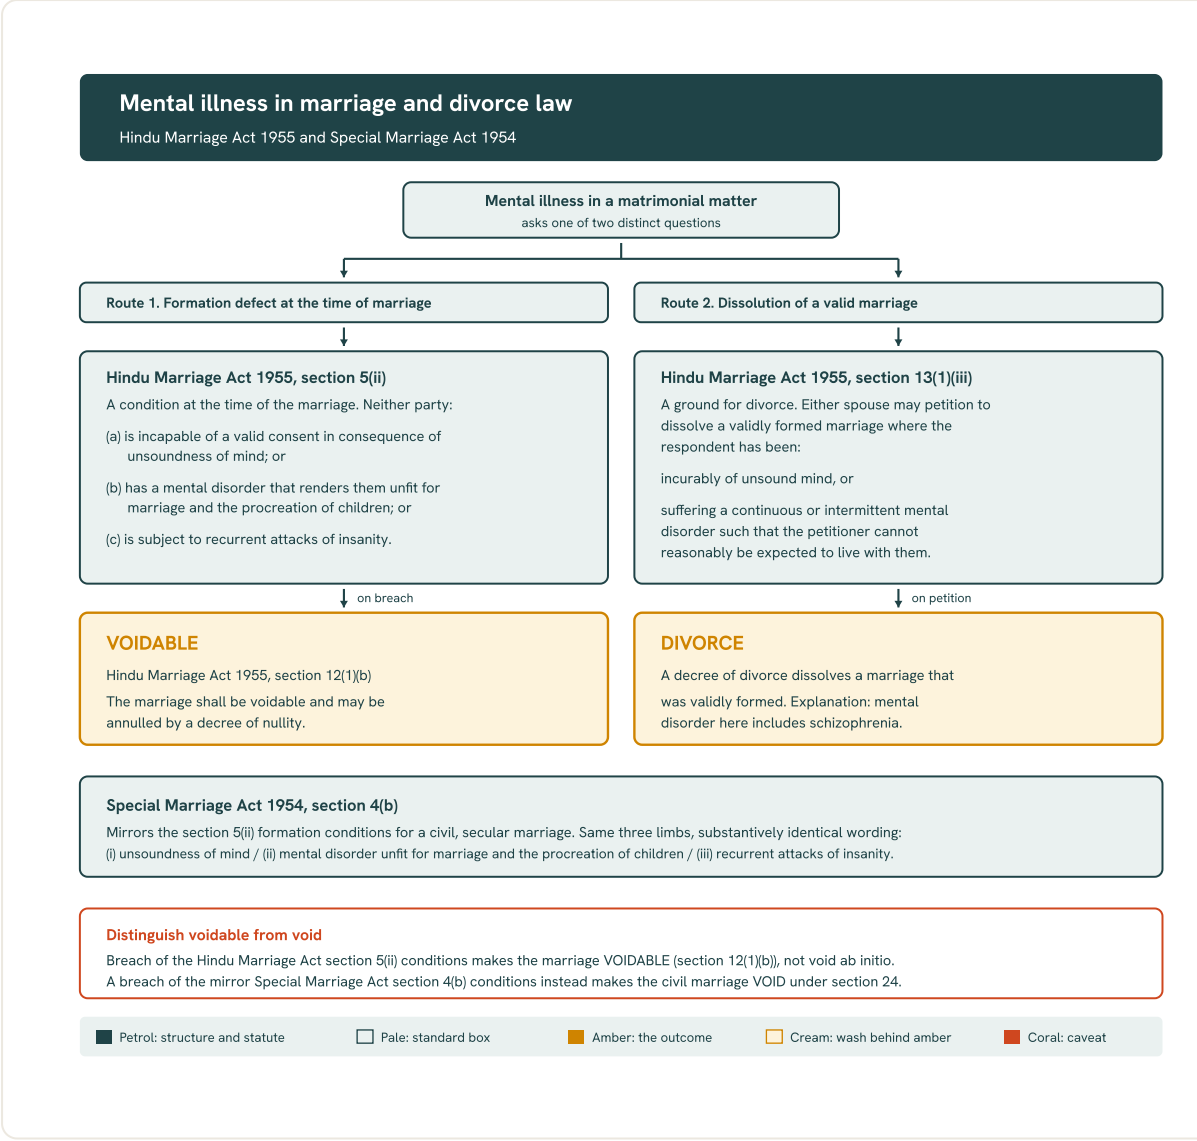

Fig 25.14. Mental illness reaches a marriage by two distinct routes. A formation defect under Hindu Marriage Act 1955 section 5(ii) makes the marriage voidable (section 12(1)(b), annulled by a decree of nullity), while section 13(1)(iii) is a ground to dissolve a validly formed marriage by divorce; the Special Marriage Act 1954 section 4(b) mirrors the formation conditions, but a breach of them makes a civil marriage void under section 24, not voidable.

31.1 The mental-capacity condition for a valid Hindu marriage

The conditions for a valid Hindu marriage are set out in the Hindu Marriage Act of **1955**, and the mental-capacity condition among them is clause (ii) of section **5(ii)**. The Act permits a Hindu marriage to be solemnised only where the conditions in that section are fulfilled, so this is a **formation condition**: it looks at the parties as they were at the time of the marriage and asks whether the marriage was well made, and it is indifferent to anything that befalls either of them afterwards. That temporal anchor is the whole of the topic. A condition that speaks to the moment of formation cannot be satisfied or defeated by a later illness, and a later illness cannot be crammed into it; that is what separates this ground from the neighbouring divorce ground and is where most candidates lose the mark.

The condition is breached if, at the time of the marriage, either party falls within any one of three alternative situations:

- is incapable of giving a valid consent to the marriage in consequence of unsoundness of mind;

- though capable of giving a valid consent, has been suffering from mental disorder of such a kind or to such an extent as to be unfit for marriage and the procreation of children; or
- has been subject to recurrent attacks of insanity.

The clause in its present form is not original to the Act as first enacted. It was substituted by **Act 68 of 1976**, the reform that recast the mental-capacity requirement into the three-limbed shape now examined. Reading the current text as though it were the Act as first enacted is a small but common error, and the wording the paper tests is the substituted wording, not what stood before it.

31.2 Reading the three limbs apart

The three situations are alternatives, not a cumulative test: any one of them, present at the time of the marriage, breaches the condition, and they are worth separating because they weigh quite different things. The first turns on consent. Here the disturbance is grave enough that the person is **unsoundness of mind** incapable of giving a valid consent to the marriage at all; the defect is in the very act of agreeing, so the marriage rests on a consent the law does not recognise. The second limb assumes the opposite starting point. The person can give a valid consent, and does, but carries a mental disorder of such a kind or to such an extent as to render them **unfit for marriage and the procreation of children**. This is a fitness test rather than a consent test, and its threshold is one of gravity: a diagnosis is not enough, the disorder must reach the kind or the extent the clause names. The third limb is the person **recurrent attacks of insanity**, and it captures a relapsing course rather than a settled state, using the archaic statutory word that the substituted clause retained.

The middle limb is the one that repays care, both because its threshold is a matter of degree and because its procreation-linked wording sits awkwardly with the modern rights-based understanding of mental illness and disability; a candidate should reproduce the clause as it stands while recognising that the phrase has drawn sustained criticism. Note too that the clause speaks of "mental disorder", a term the Act defines for the purpose of its divorce ground; that definition belongs to the topic on dissolution and is not restated here, and it should not be read across uncritically to the formation condition. What the formation limbs share is the moment they examine: each asks about the mind at the time of the marriage, and none is concerned with what the illness does to the marriage years later.

MNEMONIC

Consent, Fitness, Freedom

The three alternative situations of the mental-capacity condition, in order: incapacity of **Consent** through unsoundness of mind; a mental disorder that defeats **Fitness** for marriage and the procreation of children despite valid consent; and the absence of **Freedom** from recurrent attacks of insanity. Any one, present at the time of the marriage, breaches the condition.

31.3 The Hindu Marriage Act consequence: voidable, not void

The consequence of breaching the mental-capacity condition is the second half of the topic, and it is stated precisely at section **12(1)(b)**. A marriage in contravention of the condition in clause (ii) of the conditions section shall be **voidable** and may be annulled by a **decree of nullity**. The two modal verbs are doing exact work and must be preserved. The marriage *shall be* voidable, which fixes the category the defect falls into; a party *may* then seek annulment, which is discretionary in the sense that it depends on a party bringing the petition and on the court granting a decree. A voidable marriage is not the same thing as no marriage. It is valid and fully effective for every purpose until a party obtains a decree, and if no one ever petitions it stands. That is the opposite of a **void ab initio** union, which the law treats as never having been a marriage at all and which needs no decree to be a nullity.

Why the distinction bites. It is not academic. It decides who can act, when the marriage ends, and from what point. Because a Hindu Marriage Act mental-capacity breach yields a voidable marriage, the union survives until it is set aside at the instance of a party, and children and property questions are answered against a marriage that existed in law up to the decree.

AXIS	VOID MARRIAGE	VOIDABLE MARRIAGE
What the law treats it as	never a valid marriage at all	a valid marriage until it is annulled
Status before any decree	a nullity from the outset	valid and fully effective
Who ends it, and how	no decree is needed to treat it as a nullity, though one may be sought	only a party may petition, and the court may annul by a decree of nullity
Where a Hindu Marriage Act mental-capacity breach sits	not here	here - contravention of the clause (ii) condition

RULE **Under the Hindu Marriage Act, a mental-capacity defect at the wedding makes the marriage voidable, not void.** Breach of the formation condition renders the marriage liable to be set aside on a party's petition; until a decree of nullity is granted the marriage is valid for all purposes. The Hindu Marriage Act says the marriage shall be voidable and may be annulled, and the candidate must keep both verbs and must not upgrade this ground to a void marriage. The Special Marriage Act runs the other way: there the same breach is void, so the void-or-voidable answer turns on which Act governs.

31.4 The Special Marriage Act: same condition, void not voidable

The civil, secular route to marriage is the Special Marriage Act of **1954**, a form of civil marriage open irrespective of religion, which the parties may solemnise in whatever form they choose since the Act does not require a religious ceremony, subject to the Act's conditions and to the current law. This is the Act's solemnisation chapter, and it is this chapter, not the Act's separate provision for registering a marriage already performed in some other form, that carries the mental-capacity condition examined here. Its mental-capacity condition is clause (b) of section **4(b)**, and its three limbs are substantively identical to the Hindu Act's: incapacity of valid consent through unsoundness of mind; a mental disorder of such a kind or extent as to be unfit for

marriage and the procreation of children despite capacity to consent; and recurrent attacks of insanity. The same clinical test therefore serves both statutes, so the psychiatric opinion does not change with the Act. What changes, and this is the discrimination the paper rewards, is the consequence of a breach. Under the Hindu Marriage Act a breach of the mental-capacity condition renders the marriage voidable under section **12(1)(b)**, valid until a party has it annulled; under the Special Marriage Act a marriage solemnised under that chapter with the same breach is **null and void** under section **24**, a nullity from the outset that a party may have declared by a decree of nullity. A civil marriage solemnised under this chapter that fails the mental-capacity clause is therefore void, not merely voidable, and this void-versus-voidable split between the two Acts, on identical clinical facts, is the examined point. Registration of a marriage already performed in some other form is a separate current route under the Act, carrying its own condition on the parties' mental state at registration and its own, milder consequence for breach, namely that the registration rather than the marriage may be declared of no effect; that registration route is not restated here. The practical work is to cite the Act that governs the marriage in front of you and the consequence that Act attaches to a breach. That section also sets the Act's other conditions for a valid civil marriage, including that neither party already has a living spouse and that each has reached the minimum age the Act fixes for a bride and a groom; those are named here only to place the mental-capacity clause within its section, and are not the psychiatric ground.

IN INDIA

The clinical opinion is identical across the two statutes; what changes is the governing Act, and with it the section cited and the void-or-voidable consequence a breach carries. A marriage solemnised under Hindu personal law is tested against the Hindu Marriage Act, while a civil or inter-faith marriage is tested against the Special Marriage Act, and comparable mental-capacity conditions run through the other personal-law statutes with wording of their own. Match the governing Act to the parties before framing the report, because quoting the wrong statute for the right facts is an avoidable and much-penalised slip in a viva.

31.5 Nullity is a formation defect, not a divorce ground

The title of this topic pairs marriage with nullity, and the trap the paper sets is the line between nullity and divorce. Nullity, the route owned here, rests on a defect present when the marriage was formed: the mind was not fit to marry at the wedding, so the marriage was defective at its formation and may be unravelled by a decree. Divorce is the opposite premise. It is the **dissolution** of a marriage that was validly formed and subsisting, brought to an end for a reason that matters now, and where mental illness is the reason it operates as a ground of divorce with its own threshold. That dissolution ground is taken up as its own topic elsewhere in this chapter and is not restated here; what this section owns is the formation defect and the nullity that follows from it.

The reason the distinction earns marks is not that a single variable, the timing of the illness, sorts the same facts into one route or the other. Nullity and divorce ask different questions of those facts. Nullity asks whether the mental-capacity condition in section **5(ii)** stood breached at the

time of the marriage; if it did, the marriage is voidable under section **12(1)(b)** and may be annulled, whatever course the illness took afterwards. Divorce under section **13(1)(iii)** asks a different question: it presupposes a validly formed and still subsisting marriage and turns on whether the illness now meets the statutory severity threshold that ground sets, irrespective of when the disorder first began. Timing is therefore decisive for one question only, whether the section **5(ii)** condition was breached at solemnisation, and it does not by itself fix which remedy the facts will support: a disorder that predated the wedding can found a nullity petition if it breached the condition then, and can equally found a divorce if the marriage was validly made and the dissolution threshold is now met. This is why the psychiatric history should still fix onset against the date of the marriage as precisely as the records allow, but as evidence going to the formation condition, not as a switch that routes the whole case.

TRAP **Reading a formation defect as a divorce ground, or the reverse.** Facts that show incapacity or unfitness at the time of the marriage answer the nullity question; facts that show a grave illness arising within a valid marriage answer the divorce question. Citing the dissolution ground for a defect present at the wedding, or the formation condition for an illness that developed later, answers the wrong question and forfeits the mark.

PITFALL

Two currency-and-scope errors recur in practice. The first is treating a voidable marriage as if it were void from the outset, and advising a family that "there is no marriage" when in law the marriage stands until a party obtains a decree. The second is conflating the formation ground with the divorce ground, so that a clinician frames an opinion about a spouse's current illness as though it bore on the validity of the wedding years earlier. Both overstate what the statute allows and mislead the very people who have come for guidance.

31.6 The psychiatrist in nullity proceedings

Because the condition is anchored to the moment of the marriage, the assessment is almost always retrospective and is functional rather than diagnostic. By the time a nullity petition reaches a psychiatrist the wedding may be long past, so the opinion is reconstructed from contemporaneous records, informant accounts and any independent evidence of the party's mental state around the date of the marriage. The task is not to certify a diagnosis or to pronounce the person globally sound or unsound, but to map the statutory limbs onto that moment, and the enquiry follows the section's own structure:

- the diagnosis, and how securely it can be made for the relevant period;
- the mental state at the time of the marriage, reconstructed as far as the evidence allows;
- whether, on the first limb, the person could give a valid consent to the marriage;
- whether, on the second limb, a disorder reached the kind or extent that makes for unfitness for marriage and the procreation of children;
- the course of the illness, and whether it ran in the recurrent pattern the third limb describes.

The burden of establishing the ground rests on the party seeking nullity, and the ground must be proved on the whole admissible evidence; medical evidence is ordinarily important, especially where available, but is not an invariable statutory prerequisite, so the quality of the reconstruction frequently decides the case. That makes candour about the limits of a retrospective opinion a professional duty rather than a weakness: where the contemporaneous record is thin, the honest report says so and frames the view as an inference, since an overstated opinion does the petitioner's work while damaging the witness. How the opinion is finally put before a court, the form of the expert report and the duties of the expert witness, is not family law and is treated in the Forensic ethics, consent and legal procedure notes; here the content of the opinion is dictated entirely by the limbs and by the moment at which they must be shown.

GOOD TO REMEMBER

Pitch the opinion to the wedding, not to the clinic today. Set out the diagnosis, the mental state at the time of the marriage, and whether the person could consent or was rendered unfit, and tie each finding to the limb it bears on. Resist a global "of unsound mind" verdict, which is not what the court can act on, and where the historical evidence will not support a firm view, say the evidence is insufficient rather than filling the gap with an impression.

The mental-capacity condition for a valid marriage is judged at the time of the marriage, and its breach is a defect of formation, never a ground of divorce; under the Hindu Marriage Act that breach makes the marriage voidable and annullable by a decree of nullity, while under the Special Marriage Act the same breach makes the marriage void from the outset.

32 · Divorce and annulment on grounds of mental illness

Where the marks sit. A marriage can end in law in more than one way, and the psychiatrist is drawn in whenever mental illness is said to be the reason. The route addressed here is divorce - the dissolution of a marriage that was validly contracted and subsisting - on the ground that the other spouse is mentally ill. Under the Hindu Marriage Act of **1955** this ground lives at section **13(1)(iii)**, and it is worded with a precision the examiner rewards: it is not enough that a spouse carries a psychiatric diagnosis. The section asks a question about severity, endurance and curability, and it leaves the final decision to the court.

Most of the marks turn on keeping divorce apart from nullity, and a diagnosis apart from a legal ground: dissolving a valid marriage is a different legal act from declaring one void or voidable for a defect present when it was formed, and naming a disorder is not the same as satisfying the statutory threshold. Keep those distinctions clear and the topic is secure.

32.1 A dissolution ground, and its pedigree

Divorce is the **dissolution** of a subsisting, validly formed marriage: the union existed in law and is now brought to an end by a **decree of divorce**. Holding that firmly is the key to placing this ground correctly, because the same clinical facts can be argued along a quite different legal route. Under the Act a marriage "may ... be dissolved" on the mental-illness ground, and the verb is

doing real work: dissolution is discretionary and judicial, so even where the clinical picture is made out the court is asked to grant a decree, not compelled to. The petition may be presented by either the husband or the wife, and the ground looks throughout to the other party's condition, so a petitioner cannot found the case on their own illness. The mental-illness ground sits among the Act's other grounds of divorce, but it is the one that turns squarely on psychiatric evidence, which is why the clinical case the section needs falls to the psychiatrist to build rather than to the lawyer.

The clause in its present form is not original to the Act as first enacted. It was substituted by **Act 68 of 1976**, the reform that recast several of the fault grounds and, importantly, attached a statutory Explanation defining what "mental disorder" means for this purpose. Reading the current wording as though it were the original provision is a common slip; the definitions that make the ground workable were a later addition, and it is those definitions the examiner most often tests.

1955	13(1)(iii)	1976
HINDU MARRIAGE ACT	MENTAL-ILLNESS GROUND	EXPLANATION ADDED

32.2 The alternative limbs of the ground

The section gives the petitioner alternative ways of making out the same ground, set down as one or the other and not as a single combined test. The first is that the respondent has been **incurably of unsound mind**. Here the operative words are unsoundness and, decisively, its incurability: a disturbance that can be cured, however severe while it lasts, does not answer this limb. The second is that the respondent has been suffering, continuously or intermittently, from **mental disorder** of such a kind and to such an extent that the petitioner cannot reasonably be expected to live with the respondent. This limb says nothing about cure; its test is one of gravity and of the effect of that gravity on married life.

The phrase "continuously or intermittently" in the second limb is deliberate and clinically apt. A relapsing and remitting illness that returns in episodes is not taken outside the ground merely because the respondent is well between them; what the limb asks is whether the disorder, taken as it actually runs, reaches the kind and extent that makes cohabitation unreasonable. The limbs are worth pulling apart because they weigh different things: the first asks whether the condition can be cured, the second asks whether, cure or no cure, the disorder is grave enough that continued life together cannot reasonably be expected of the petitioner. In clinical terms the hard work usually lies in the first limb, because incurability is a strong and unforgiving word - a prognosis of persistent, treatment-refractory illness is a very different assertion from a diagnosis, and it should be offered only where the course genuinely supports it. A candidate who runs the limbs together, importing incurability into the second or dropping the cohabitation test from it, has misread the clause.

AXIS	FIRST LIMB: INCURABLE UNSOUNDNESS	SECOND LIMB: GRAVE MENTAL DISORDER
Statutory core	the respondent "has been incurably of unsound mind"	a "mental disorder ... of such a kind and to such an extent" that cohabitation cannot reasonably be expected
What must be shown	unsoundness of mind, and that it is incurable	a qualifying mental disorder of sufficient kind and extent
Does curability decide it	yes - incurability is itself the threshold	no - severity and its effect on married life are
Course of the illness	a settled, enduring unsoundness	may be continuous or intermittent
The question for the court	can the condition be cured	can the petitioner reasonably be expected to live with the respondent

32.3 What the Act means by "mental disorder"

The reason this ground is examinable, and not merely a gesture at illness, is that the Act refuses to leave "mental disorder" to ordinary usage. The Explanation to the clause defines it, and defines it broadly. For this purpose "mental disorder" is stated to mean:

- mental illness;
- arrested or incomplete development of mind;
- **psychopathic disorder**; or
- any other disorder or disability of mind;
- and it is expressly stated to include **schizophrenia**.

Two features of the definition repay attention. It is a broad means-and-includes definition: the defined categories are exhaustive at category level, but one category, "any other disorder or disability of mind", is itself a wide catch-all, and "arrested or incomplete development of mind" brings intellectual disability within the term rather than confining it to psychotic illness. The express naming of schizophrenia is the detail candidates remember, and it is a real feature of the provision - the most litigated diagnosis was put beyond argument as to whether it can, in principle, count.

The Explanation also defines psychopathic disorder in its own right: a persistent disorder or disability of mind, whether or not it includes sub-normality of intelligence, that results in abnormally aggressive or seriously irresponsible conduct on the part of the respondent, and it holds whether or not the condition requires or is susceptible to medical treatment. That last clause is easily missed and worth stressing: a psychopathic disorder can found the ground even if it is untreatable or needs no treatment, because the definition turns on the resulting conduct, not on treatability. The breadth of the definition has a practical consequence worth carrying into the witness box: a psychiatric label will rarely take a genuine condition outside "mental disorder", so

the real contest in almost every case is not whether the condition counts but whether it reaches the threshold the limbs set.

32.4 A threshold, not a diagnosis

The crux of the topic. Because the Act names disorders and even singles out schizophrenia, it is tempting to read the ground as satisfied the moment a diagnosis is made. It is not. The definition of "mental disorder" tells you which conditions are capable of founding the ground; it does not tell you that every instance of them does. Each limb imposes a further test that is about degree rather than label - incurability on the first, and a kind and extent that makes cohabitation unreasonable on the second. A stable, treated illness, or a diagnosis that leaves the person able to sustain married life, meets neither.

Consider a respondent whose illness is well controlled between relapses and who functions in the marriage for long stretches. The diagnosis is not in doubt, yet neither limb may be made out: the first is defeated by treatability, and the second by the absence of the required gravity. The section's questions are answered by the course and the consequences of the illness, not by its name in the case notes. This is where the clinical and the legal part company - the diagnosis is a clinical fact the psychiatrist can supply, but whether it reaches the statutory threshold is a mixed question the court decides on the whole of the evidence.

RULE **The ground is a threshold, not a diagnosis.** The Act asks how grave the condition is and, on the first limb, whether it is incurable, not merely what it is called. Naming a disorder, schizophrenia included, establishes only that it is capable of founding the ground; the petitioner must still prove the incurability, or the kind and extent, that the section actually demands.

PITFALL

Asked whether a spouse's illness "is a ground for divorce", a clinician may answer yes on the strength of the diagnosis alone, encouraged by the Act expressly listing schizophrenia. The express inclusion only makes a disorder capable of founding the ground. Treating the diagnosis as though it settled the legal question overstates what the clinical evidence can carry and steps into the court's role of applying the statutory test.

32.5 Divorce is dissolution, not nullity

The title of this topic pairs divorce with annulment, and that pairing is exactly where candidates come to grief. Divorce dissolves a marriage that was validly formed and subsisting, and it operates from the date of the decree forward. **Nullity**, or annulment, rests on the opposite premise: it is a finding that the marriage was void, or voidable and then set aside, because something was wrong at its very formation. Mental illness can feature in both routes, but it enters through different doors. As a divorce ground it speaks to a condition that makes the continued marriage unsustainable; as a nullity ground it speaks to a defect of capacity or consent that was present when the marriage was contracted.

The consequences differ, which is why the distinction is not merely formal. A decree of divorce accepts that a marriage existed and brings it to an end; a decree of nullity treats the marriage as

never having been valid, or unravels it from the outset. In practice the same clinical picture can be pleaded along either route, but what selects the route is whether the marriage was validly formed, not when the illness began: the divorce ground presupposes a valid, subsisting marriage and asks only whether the condition reaches the threshold, so an illness that predated the wedding can still found a divorce where the marriage was validly contracted and the severity test is met. Onset relative to the marriage bears on the nullity question alone, whether a disqualifying condition existed at solemnisation and so vitiated the formation, so the psychiatrist should record onset for that inquiry without treating a pre-marital start as evidence against divorce. The formation conditions, the void and voidable categories and the nullity procedure are taken up as their own topic, in the account of marriage and nullity elsewhere in this chapter, and are not restated here; what this section owns is the dissolution ground and its threshold.

TRAP **Reading a formation defect as a divorce ground, or the reverse.** Facts that show unsoundness or want of capacity at the time of the marriage point to nullity, because they go to how the marriage was formed. Divorce, by contrast, dissolves a validly formed and subsisting marriage whenever the respondent's condition meets the statutory threshold, whether or not the illness began after the wedding. Citing the dissolution ground for a genuine formation defect is one error; treating a pre-marital onset as by itself a bar to divorce, when the marriage was validly contracted and the threshold is met, is the other.

32.6 The psychiatrist in matrimonial proceedings

In practice the psychiatrist is brought in to examine the respondent, or to comment on the records, and to give the court an opinion pitched to the statutory limbs. The burden of proving the ground rests on the petitioner, and the mental-illness ground is proved on the whole of the legally admissible evidence, medical evidence being ordinarily important, especially where available, but not an invariable statutory prerequisite, so the quality of the psychiatric opinion frequently decides the case. What the examination should capture follows the section's own structure:

- the diagnosis, and how securely it can be made;
- the current mental state and its severity;
- the course, whether continuous or intermittent;
- the prognosis, and specifically whether the condition is curable;
- the functional impact on the capacity for married life.

The opinion is then framed to the section: address curability squarely where the first limb is in play, and kind and extent where the second is, and leave the ultimate question of whether the marriage should end to the court. That opinion is often retrospective and always partial, since the examiner may be meeting the respondent long after the events pleaded, so it should be pitched with candour about its limits, because an overstated report does the petitioner's work while weakening the witness. How the psychiatrist actually gives that evidence - the form of the expert report, the duties of the expert witness and the conduct of testimony - is not family law and is

treated in the Forensic ethics, consent and legal procedure notes; here the point is only that the clinical content is dictated by the limbs and by the thresholds each of them sets.

IN INDIA

Indian courts have read the qualifying threshold strictly: neither a bare diagnosis nor a spell of psychiatric treatment establishes the ground by itself, and the petitioner must show on the evidence that the statutory test, incurability or a disorder of the required kind and extent, is actually met. Comparable mental-illness grounds run through the other personal-law statutes and the secular marriage law, though their wording and their thresholds differ, so the governing provision must be matched to the parties before the clinical opinion is shaped.

GOOD TO REMEMBER

When you examine a spouse for matrimonial proceedings, keep the opinion clinical: set out the diagnosis, severity, course, prognosis and curability, and the impact on the capacity for married life, and map each to the limb it bears on. Resist being drawn into whether the marriage should be dissolved, which is the court's question and not the clinician's, and where the evidence is thin, say so rather than filling the gap with an impression.

The divorce ground for mental illness dissolves a valid marriage only where the petitioner proves incurable unsoundness of mind, or a mental disorder so grave that cohabitation cannot reasonably be expected; a diagnosis alone, schizophrenia included, is never enough.

33 · Child custody and psychiatric evaluation

Why the marks are here. A custody question reaches the psychiatrist because a court has to decide something it cannot observe for itself: which arrangement will let a particular child grow up safe, stable and well. When one parent has, or is alleged to have, a mental illness, the court needs someone to translate that illness into what it actually means for the day to day care of the child. The examiner is testing three things at once - that you lead with the principle the whole area turns on, that you will not mistake a diagnosis for the answer, and that you understand the limits of your own role. Get those three right and the rest of the answer writes itself.

State the governing idea before anything else, because every later step serves it. In an Indian custody matter the **welfare of the child** is the paramount consideration, standing above the claims of either parent. The **Guardians and Wards Act 1890**, which applies across communities, and the **Hindu Minority and Guardianship Act 1956**, which applies to Hindus, both make the child's welfare the decisive test. The psychiatric evaluation exists to inform that test, and nothing more.

In an Indian custody dispute the child's welfare is the paramount test; a parent's mental illness counts only through its effect on parenting capacity and on the child, and the psychiatrist informs the decision without making it.

Welfare	Function	Informs	Both
THE PARAMOUNT TEST	NOT THE DIAGNOSIS	THE COURT STILL DECIDES	PARENTS AND CHILD ASSESSED

33.1 The welfare principle and the statutory frame

Custody is decided by the court acting as **parens patriae**, the guardian of those who cannot protect their own interests. This is why the parents' wishes, their relative wealth, and even the ordinary preferences written into personal law are all subordinate to a single question: what does this child need. It helps to separate two ideas that candidates routinely blur. Custody is the day to day care and control of the child; guardianship is the wider legal authority over the child's person and property. A parent may hold custody while the framework of guardianship sits elsewhere, and the welfare test governs both.

Both governing statutes point the same way. Where a personal law names one parent as the preferred natural guardian, that preference *yields* the moment it collides with the child's welfare, because welfare, not lineage and not gender, is the criterion the court is bound to apply. In practice the court weighs the age and sex of the child, the continuity and stability of the child's existing environment, the character and capacity of each parent, the child's own ascertainable wishes, and any threat to safety. None of these is applied mechanically; they are balanced against one another, and the psychiatric evaluation feeds several of them at once.

RULE **Custody turns on the child's welfare, not on a parent's label.** The statutes make welfare the decisive test, so the evaluation exists to translate any parental illness into its concrete effect on care and on the child, and to stop precisely there. An opinion that says more than that has stepped outside the psychiatrist's remit and into the court's.

33.2 From status to function: why a diagnosis does not decide

The single most important clinical and legal move in this area is the shift from status to function. A diagnosis is a status; parenting is a set of functions. A parent's mental illness is not, by itself, disqualifying. What the law asks is whether, and how, the illness affects the parent's capacity to care for this child and the welfare of the child, never the name of the condition on the certificate. This is also the posture the modern rights-based framework of disability law expects: a person is not defined, and must not be written off, by a diagnostic label.

Worked through, the discrimination is straightforward. A parent whose illness is well treated, who has insight, who adheres to treatment and who has a supportive network may parent perfectly well, and a diagnosis alone neither proves nor disproves that. An illness becomes relevant only through its functional consequence: active psychosis with command phenomena that concern the child, a manic episode with reckless endangerment, a depression so severe that a young child is left unfed or unsupervised, or disorganisation that removes basic protection. In each of those the concern is what the parent cannot currently do for the child, not the diagnostic heading under which it falls. The evaluator's job is to make that functional link explicit, or to say clearly that no such link exists.

TRAP **Treating a diagnosis as automatic unfitness.** Candidates write that a parent with schizophrenia or bipolar disorder should lose custody. The law asks for the effect of the illness on parenting and on welfare, not for the diagnosis; a well-treated, insightful, supported parent may care for a child perfectly, and a label on its own decides nothing. Answer with function, and the mark follows.

33.3 Parenting capacity: what the evaluation actually assesses

The core of the psychiatric evaluation is an assessment of **parenting capacity**: not whether a parent is ill, but whether the parent can meet this particular child's needs, now and in the foreseeable future. It is a functional, here-and-now and forward-looking judgement, and it is best broken into domains that can each be observed, described and, where necessary, defended under cross-examination:

- basic care and physical safety - feeding, supervision, medical needs, and protection from harm;
- emotional availability and warmth - the capacity to attune to the child and to respond to distress;
- consistency, structure and boundaries - predictable routines and reliable containment;
- a realistic understanding of the child's developmental and emotional needs;
- the capacity to place the child's needs above one's own, including during adult conflict;
- willingness to support the child's relationship with the other parent rather than obstruct it.

The last domain matters more than trainees expect. A parent who actively works to poison the child's bond with the other parent is displaying a parenting deficit, whatever their diagnostic status, and a parent with an illness who nonetheless protects that bond is showing real capacity. Capacity is established not by assertion but by method: an interview and mental state examination of each parent, a developmental and psychiatric history, and, above all, direct observation of each parent interacting with the child. What a parent describes and what a parent does with the child in the room are different data, and the evaluation needs both.

MNEMONIC

Parent, Child, Fit, Risk

A custody evaluation moves through the **parent** (the parenting capacity of each caregiver), the **child** (developmental needs, attachments and age-weighted wishes), the **fit** between them (how well each parent meets this particular child's needs), and the **risk** to the child's safety. The four run in the order a careful assessment actually follows, and none of them is the diagnosis.

33.4 The child's side: attachment, needs and age-weighted wishes

An evaluation that examines only the parents has done half the work. The child is assessed in their own right. The quality and security of the child's **attachment** to each caregiver, and the continuity of care the child has actually experienced, carry real weight, because welfare is a matter of relationships and stability rather than an idealised parent chosen in the abstract.

Developmental needs shift with age, and an arrangement that serves an infant well may fail an adolescent; the evaluation is always about this child at this stage, not a generic child.

The child's own voice. The child's wishes are ascertained and given weight according to age and maturity - the more developmentally mature the child, the more their stated preference counts, without it ever becoming the sole determinant. Here the evaluator must tread carefully. A child's stated preference can be authentic, or it can be coached, or it can reflect a wish to placate the more frightening parent or to protect the more fragile one. Eliciting the child's voice sensitively and alone, and interpreting it against the whole picture rather than taking it at face value, is a skill the examiner expects you to name explicitly. The child is heard; the child is not asked to choose.

33.5 Risk to the child within the evaluation

Safety is the threshold that sits inside welfare: no arrangement can be in a child's interest if it exposes the child to harm. The evaluation therefore screens actively for risk - domestic violence, substance misuse, neglect, and physical, sexual or emotional abuse - as well as for danger arising directly from untreated parental psychopathology. **Parental alienation**, in which one parent systematically corrodes the child's relationship with the other, is itself a form of emotional harm to the child and belongs squarely in the risk formulation rather than being dismissed as ordinary post-separation hostility.

Where abuse of a child is alleged or suspected, the matter stops being a purely private custody dispute and engages the statutory child-protection machinery. The child-protection statutes, and the systems that assess and safeguard children at risk, are set out in the Child psychiatry: assessment, treatment, services and protection notes; the custody evaluator's task is to recognise the threshold, document the concern accurately, and route it into that machinery, not to adjudicate the abuse allegation itself. Confusing the two - trying to prove or disprove abuse within a custody opinion - is how an evaluator exceeds both competence and remit.

33.6 Method and the limits of the psychiatrist's role

A defensible custody opinion rests on more than one voice. The evaluator interviews and examines each parent, observes each parent together with the child, sees the child sensitively and alone, and gathers **collateral information** from school, treating clinicians, and documentary records. Triangulating these sources is precisely what protects the opinion from a single parent's partisan account, and it is the difference between an assessment and an endorsement.

The most important boundary is the one written into the nature of the task: the psychiatric evaluation informs the court's welfare determination, it does not make it. The evaluator describes parenting capacity, the child's needs and attachments, and any risk, and shows the reasoning that connects them; the choice of custody arrangement remains the court's alone. Staying inside that boundary is not diffidence, it is the correct forensic posture, and it is what keeps the opinion admissible and useful. The wider ethics of acting as an expert - confidentiality in the forensic setting, the avoidance of a mixed treating and evaluating role, and the certification of a report or

opinion for the court - are the subject of the Forensic ethics, consent and legal procedure notes, and are named here rather than taught.

PITFALL

Forming a view from one parent's account without ever observing the child, seeing each parent together with the child, or gathering independent collateral. A custody opinion built on a single, interested informant is unsafe, it tends to import that informant's bias unexamined, and it rarely survives cross-examination.

GOOD TO REMEMBER

Write your opinion as parenting capacity and welfare, never as a verdict on the parent. Say what each parent can and cannot do for this particular child and why, flag any risk plainly, and leave the arrangement itself to the court. An opinion framed this way is both more useful to the judge and far harder to discredit.

33.7 The components at a glance, and how it is examined

Set out side by side, the evaluation separates cleanly on what each part examines and how each part goes wrong. The accompanying table lays out the axes an examiner tests; commit the structure, because a viva question almost always asks you to reason across the whole assessment rather than recite one piece of it.

AXIS	WHAT IT EXAMINES	WHY IT MATTERS	COMMON ERROR
The parent	Parenting capacity: safety, warmth, consistency, insight, the ability to prioritise the child, support for the other parent's contact	Determines whether care will be adequate and stable	Reading the diagnosis instead of the function
The child	Age, developmental needs, attachments, and age-weighted wishes	Anchors the decision in this child's actual needs	Ignoring the child's voice, or over-weighting a coached wish
The fit	How well each parent meets this particular child; continuity of care and environment	Welfare is about a relationship, not a parent in isolation	Assessing parents in the abstract
The risk	Violence, substance misuse, neglect, abuse, alienation, illness-driven danger	Safety is the threshold within welfare	Missing risk by focusing only on capacity

IN INDIA

Indian courts decide custody as guardians of the child, and the welfare test cuts across community and personal law: even where personal law names a preferred natural guardian, that preference gives way to the child's welfare. Custody of a child of **tender years** is often, though never automatically, entrusted to the mother on a welfare rationale rather than by a fixed rule. Because custody usually arises within divorce or judicial-separation proceedings, the psychiatrist is generally asked for an opinion in a matrimonial context in which feelings run high and each side may try to recruit the evaluation to its own case. The welfare test, however, is distinct from and outlives the question of whether the marriage itself survives, and the evaluation should be framed to serve the child even when the adults are framing it to serve themselves.

In the examination this topic rewards the candidate who leads with the welfare principle, refuses to be drawn into equating a diagnosis with unfitness, describes a structured multi-source evaluation, and states plainly that the psychiatrist informs but does not decide. Say those four things clearly, name the two governing statutes, and the answer reads as the work of someone who has actually stood in the witness box rather than only read about it.

34 · Guardianship and management of property of mentally ill

Why the marks are here. When mental illness erodes a person's ability to look after money, land and everyday affairs, the law is asked to do two things at once: shield the person and the estate from loss and from exploitation, while intruding on their autonomy no more than the situation demands. The mechanism it reaches for is the guardianship of property and the appointment of someone to manage the estate. For the examiner this is less a topic than a discrimination. Mental illness can trigger several distinct legal offices, and candidates routinely fold them into one. The task is to hold the property-management route apart from the healthcare-facing office and from treatment-decision capacity, and to know that the framework a psychiatrist works inside today is not the custodial one the older textbooks were built around.

34.1 From custody of the estate to management of it

The oldest Indian machinery for the property of the mentally ill treated the ill person as a ward to be taken in charge. Under the colonial lunacy law the emphasis was custodial: the state, through the court, assumed control of the estate of a person found to be of unsound mind and installed someone to hold it. That **custodial guardianship** of the estate has been superseded. The modern posture begins from the presumption that legal capacity is retained, treats impairment as specific to particular decisions rather than a global forfeiture of legal personhood, and asks for the least intrusion that will protect the person and the property. The rights-based reworking of guardianship for the disabilities it covers, under the disability-rights statute and the National Trust legislation, is set out with the account of benefits, reservations and guardianship elsewhere in these notes. What remains here is the ordinary statutory route, the residual position where no statute fits, and how property management differs from the healthcare offices around it.

PITFALL

The commonest real-world error is to describe property guardianship in the vocabulary of the repealed lunacy law, as though a finding of unsoundness still stripped a person of legal personhood wholesale and handed a relative standing, all-purpose control. It does not. An opinion or an application written on that assumption over-reaches the patient's rights and invites the court to reject it. Anchor the reasoning to the current, least-restrictive frame, not the custodial one it replaced.

34.2 The ordinary statutory route, and the residual jurisdiction

The ordinary route today runs through statute. Because mental illness is itself a specified disability, a person whose illness erodes decision-making is reached by the **disability-rights statute's limited guardianship**, a supported, joint model named and taught with the reform statutes elsewhere in these notes; where its covered conditions apply, the National Trust legislation runs its own committee-appointed guardianship. What there no longer is, is a free-standing, nationwide civil-court power to appoint a guardian of the person and a manager of the estate at large. The property-management machinery of the old Mental Health Act 1987, the judicial inquisition and management of the estate through the district court, was repealed with that Act and not re-enacted by the present mental-health legislation. Beyond the disability statutes, then, the position is a legislative vacuum: where no statutory route fits, the only residual power is the exceptional parens patriae jurisdiction of the chartered High Courts, derived from Clause XVII of their Letters Patent and recognised in recent Bombay High Court authority. That jurisdiction is territorially and institutionally limited, confined to those courts and their territory, and is not a general civil court supplying property management to all. These notes therefore do not assert a nationwide civil-court manager route, because none is grounded; what precisely fills the vacuum for a person outside the disability statutes and outside a chartered High Court's reach is unsettled, and is flagged here as a gap rather than invented. The psychiatrist's contribution is the same throughout: the medical evidence, a reasoned opinion framed to the particular affairs at issue, that the person's illness presently deprives them of the capacity to manage them.

Because a guardian's or manager's authority is tied to the person's incapacity, a restoration of soundness or an increase in capacity is a ground to review, reduce, dismantle or terminate the arrangement through the applicable statutory or judicial mechanism, not a universal automatic discharge. Guardianship of property is therefore a contingent trust, not a permanent status conferred by the diagnosis, and it is administered for the benefit of the ill person under the appointing forum's continuing supervision rather than handed over as ownership.

RULE **Guardianship of property is a protective trust, not a transfer of ownership or a global loss of legal personhood.** The manager administers the estate for the ward's benefit under the appointing statutory or judicial forum's supervision, which is continuing judicial oversight only where a court has made and retained that supervision; recovery or increased capacity is a ground to review, reduce, dismantle or terminate the arrangement through the applicable statutory or judicial mechanism, not a ground for automatic surrender.

34.3 Where the reform statutes take over

These statutory routes are where the ordinary work is done. For the disabilities they cover, two rights-based statutes supply the guardianship, and a candidate must be able to name them and say which person each reaches, even though their machinery is taught elsewhere in these notes. The disability-rights legislation offers a **limited guardianship** built on joint and **supported decision-making**, in which the guardian shares decisions with the person instead of displacing them. The National Trust legislation runs a separate, committee-appointed guardianship for the developmental and intellectual disabilities named in it. Both express the same instinct that runs through the modern law: support before substitution, and no more control than the person's situation needs. The practical question a psychiatrist answers is which of these doors a given patient goes through, and what medical evidence the chosen forum will want.

34.4 Property guardian versus the healthcare nominated representative

The discrimination that carries the marks separates the office that governs property from the office that supports healthcare decisions. The mental-health legislation appoints a **nominated representative** to help a person exercise and protect their rights within the mental-healthcare system. That representative is emphatically not a property guardian: they do not manage the estate, cannot deal with the person's land or money, and take no authority over civil affairs from the role. The traffic does not run the other way automatically either. A guardian or manager appointed to handle property acquires property powers, and that property appointment alone carries no power to consent to or refuse psychiatric treatment, which belongs to the separate machinery of treatment-decision capacity and its supports, discussed with the mental-health statute's capacity test elsewhere in these notes. The same person can nonetheless separately hold treatment-related authority through that statute's own nominated-representative office, most concretely for a minor, whose legal guardian is that statute's default nominated representative unless directed otherwise; that authority comes from the nominated-representative role, never from the property appointment itself. Keeping the two offices conceptually apart, while checking in a given case whether they have in fact come to be held by the same person, is both the examiner's favourite trap and a genuine clinical safeguard.

OFFICE	WHAT IT GOVERNS	WHO APPOINTS	DECISION MODEL
Limited guardian (disability-rights and National Trust routes; the ordinary statutory route)	Defined affairs of a person with the covered disability	A court or designated authority, or the National Trust committee	Supported and joint, least-restrictive
Parens patriae of the chartered High Courts (residual, exceptional)	Property and affairs where no statute fits	The chartered High Courts only, under Clause XVII of the Letters Patent	Managed for the person, court-supervised; territorially and institutionally limited
Nominated representative (mental-health legislation)	Healthcare and mental-healthcare rights only	As the mental-health law provides	Supports the person's own treatment decisions

TRAP **Treating the nominated representative as a property guardian.** Because both are triggered by mental illness and both sound protective, candidates merge them. They are different offices with different appointers, domains and decision models: the nominated representative supports healthcare choices and touches neither land nor money, while the property guardian or manager controls property but has no say over consent to treatment.

Property and money are run by a guardian or manager of the estate; healthcare is supported by the nominated representative - two separate offices, and neither reaches into the other's domain.

IN INDIA

The Indian answer is layered rather than single. The disability-rights and National Trust statutes supply the ordinary route, a modern supported guardianship for the disabilities they cover, which include mental illness; the old Mental Health Act 1987 property-management mechanism was repealed and not re-enacted, so beyond those statutes only the chartered High Courts hold a residual, exceptional parens patriae jurisdiction rather than any general civil court; and the mental-health legislation supplies the healthcare-facing nominated representative. A psychiatrist asked to help is really being asked which of these frames fits this patient, and what medical evidence the chosen forum needs to see.

34.5 Assessing capacity to manage property and affairs

What the psychiatrist actually assesses. The clinical task is a functional capacity assessment, not the pinning of a diagnosis. **Capacity to manage property and affairs** asks whether, at the relevant time, the person can understand what property they have and its broad extent, appreciate the claims of those who depend on them, weigh the choices involved in keeping or disposing of it, and communicate a decision. It is decision-specific and time-specific. A person may lack capacity for a complex commercial transaction yet retain it for ordinary spending, and capacity lost in an acute episode may return with remission. This is why the office is contingent and why recovery is a ground to review or discharge it. It also means the test is about the quality of the decision-making, not the wisdom of the outcome: a person who retains capacity is entitled to make an unwise or eccentric use of their money, and an imprudent choice on its own is no ground to displace them. What justifies intervention is an inability to carry out the reasoning, traced to the illness, and not merely a decision the family would have made differently. The same functional logic underlies the capacity to make a will and the capacity to enter a contract, each taken up on its own terms elsewhere in these notes; but they are judged against different tasks, and none of them is settled by the psychiatric label alone.

GOOD TO REMEMBER

Write the opinion as decision-specific and time-specific, tie it to the particular affairs in question, and record the prospect of recovery. State plainly that being under a property-management order does not by itself authorise anyone to consent to the patient's treatment, and that a return of capacity should trigger review of whether the management is still needed. That is what keeps the report useful to the court and protective of the patient.

35 · Fitness for job and certification of mental fitness

Why the marks are here. A psychiatrist is asked to certify fitness for a job far more often than to give evidence in any court, and it is quiet, everyday medicolegal work that the examiner likes precisely because candidates underprepare it. An employer wants to know whether a person can start a post, or return to one after illness, and turns to the treating or an assessing psychiatrist for a signed opinion. The task looks administrative, but it sits on a genuine question of capacity - can this person, in their current mental state, do this particular job safely and effectively - and it is bounded by employment law that has changed in the person's favour. The marks reward the candidate who can say exactly what such a certificate asserts, what it does not, and how it differs from the two documents it is most often confused with.

The whole difficulty of the topic is discrimination between look-alikes. A one-line signature that a person is "fit" or "unfit" can, depending on which document it belongs to, decide an appointment, unlock a statutory benefit, or sway a legal case, and the same clinician may be asked for all three about the same patient. Keeping them apart is the intellectual content the paper is testing, so it is worth taking the three certifications one at a time before turning to what a fitness opinion should actually contain.

3	3
CERTIFICATIONS TO SEPARATE	DEFINING FEATURES

35.1 Three certifications that must not be conflated

The commonest error in this area is to treat every request for a "mental fitness certificate" as one thing. It is not. The first is the **fitness-for-duty certificate**, an occupational opinion that states whether a person's current mental state permits safe and effective performance of a specified role, with any accommodations or restrictions that make that possible. It answers a forward-looking, work-focused question, and it is the document this topic owns. The second is the **disability certificate**, which does something entirely different: it quantifies impairment so that a person can access certification-linked entitlements, reservations and schemes, and its instrument, its certifying authority and its benchmark threshold are taught with the disability-certification topic in this chapter and are not to be borrowed here. The third is an **expert report or certificate for a court**, prepared as expert testimony to assist legal proceedings; that document, and the psychiatrist's duties in producing it, belong to the Forensic ethics, consent and legal procedure notes.

What separates the three is not the clinical examination, which may be similar, but the question each answers and the legal machinery each feeds. A fitness certificate is about a job; a disability certificate is about entitlement; a court report is about a legal decision. Reaching for the wrong instrument - answering a fitness-to-work request with a disability threshold, or dressing a treatment opinion as a fitness certificate - is how a clinician gives an authoritative-sounding answer to a question nobody asked.

CERTIFICATION	THE QUESTION IT ANSWERS	WHAT IT IS FOR	WHERE ITS DETAIL BELONGS
Fitness-for-duty certificate	Can this person safely and effectively do this role now?	Occupational fitness for a specified job, with accommodations or restrictions	This topic
Disability certificate	How much impairment, for statutory entitlement?	Quantifying impairment for certification-linked entitlements, reservations and schemes	The disability-certification topic in this chapter
Expert report or certificate for a court	What is the clinical opinion for these proceedings?	Assisting a legal decision as expert evidence	The Forensic ethics, consent and legal procedure notes

A fitness-for-duty certificate answers one narrow, current, role-specific question - can this person safely and effectively do this job now, and with what adjustments - and it is neither a disability certificate nor a report for a court.

35.2 What a fitness-for-duty certificate actually asserts

A sound occupational-fitness opinion has three defining features, and each is a guard against a way the certificate is misused. It is role-specific: it speaks to the demands of one named job, not to the person's general worth or employability, so a person may be fit for a desk-based role and not for one that requires night driving or the carriage of a firearm, and the certificate must say which. It is time-limited: it certifies a current state, valid for a stated review period, because a mental state is not a fixed attribute and a fitness opinion given today cannot vouch for the person indefinitely. It is evidence-based: it rests on an actual assessment of the present mental state and the specific occupational demands, not on a diagnostic label carried in the notes.

These three features are why a bare "fit" or "unfit" is a poor certificate. "Unfit", without a role, without a time frame and without a basis, tells the employer nothing they can act on lawfully or safely, and it invites them to read a temporary limitation as a permanent exclusion. The useful document names the role, states the period, and gives enough of the reasoning that the employer can see what the restriction is protecting against.

MNEMONIC

Which role, until when, on what evidence

The three features of a defensible fitness-for-duty certificate: it is **role**-specific (fit for which job, with what accommodations), **time**-limited (a current opinion with a review date, not a standing verdict), and **evidence**-based (grounded in an assessment of the present mental state against the actual demands of the post, not in a diagnosis on the file).

RULE **Fitness is a judgement about a role at a moment, not a verdict on a person.** The certificate certifies that a specified individual can, as they are now, meet the demands of a specified job safely and effectively, with any stated accommodations or restrictions, for a stated period. Every one of those qualifiers - the person, the job, the moment, the adjustments, the review date - is part of what is being certified, and dropping any of them turns a lawful, useful opinion into an over-broad label.

35.3 The functional assessment: matching the person to the role

Because fitness is defined by the job, the assessment begins with the job. The psychiatrist has to understand the actual demands of the role - its cognitive load, its interpersonal and supervisory content, its safety-critical elements, its shift pattern, its access to hazards or to vulnerable people - and then ask whether the person's current mental state allows those demands to be met. This is a **functional assessment**, not a diagnostic one: the question is what the person can do in this post, not what condition they carry, and the two do not map onto each other neatly, since a person with a serious diagnosis may be entirely fit for many roles and a person with none may be temporarily unfit for a demanding one.

Where a limitation exists, the opinion should reach for adjustment before exclusion. A **reasonable accommodation** - a modified duty, a graded return, an altered shift, a temporary reassignment away from a safety-critical task - often converts an "unfit for the role as it stands" into a "fit with these adjustments", and that is usually the more accurate as well as the more humane answer. Restrictions are the mirror image: the specific tasks the person should not perform for now, named narrowly so that everything not restricted remains open. A defensible certificate therefore records several things together rather than a single word:

- the specific role and its demands the opinion is addressed to;
- whether the person's current mental state meets those demands, and where it does not;
- the accommodations that would make the role workable, and the restrictions that should apply meanwhile;
- the period for which the opinion holds and the point at which it should be reviewed.

GOOD TO REMEMBER

Start from the job description, not the diagnosis. Ask what this post actually requires and whether the person can meet it now, then default to graded return and specific accommodations rather than a blanket "unfit". Name the restrictions narrowly and time-limit the whole opinion, so the employer knows precisely what is being protected against and for how long.

35.4 The employment-rights frame the certificate sits inside

A fitness opinion is no longer written in a vacuum in which an employer may do as they please with it. Disability, including mental illness where it amounts to a disability, is a protected ground in employment, and the certificate operates inside that protection rather than around it. This changes the clinician's posture: the default is inclusion with support, and a limitation has to be genuine, job-specific and no wider than the evidence requires, because a loosely worded exclusion can become an unlawful act when the employer relies on it.

The Indian frame. The reform is statutory, and the psychiatrist should know which way it cuts.

IN INDIA

The **Rights of Persons with Disabilities Act** protects against discrimination in employment on the ground of disability, so a psychiatric diagnosis is not a lawful reason to refuse or remove a person from a post by itself. Fitness certification therefore runs alongside a duty of non-discrimination and an expectation of reasonable accommodation, and the useful certificate is the one that supports a person into work with the right adjustments rather than one that hands an employer a broad "unfit" to exclude on. The separate disability certificate that unlocks statutory benefits, with its instrument and threshold, is a different document dealt with elsewhere in this chapter, and the two should never be run together.

PITFALL

Issuing a global or open-ended "unfit for duty" instead of a role-specific, time-limited opinion. A sweeping certificate misinforms the employer, forecloses accommodation, and can convert a temporary or partial limitation into an unlawful exclusion on the ground of disability. The clinical error is treating fitness as a standing property of the person rather than a current judgement about a particular role, and it does real harm in both directions - it can shut a capable person out of work, and it can wave through a person into a safety-critical task the evidence did not actually support.

35.5 Scenarios, boundaries and the limits of the task

The request reaches the psychiatrist in a few recurring shapes. Pre-employment screening asks whether a person can take up a post; **fitness to resume duty** asks whether a person can return after a period of illness or treatment, often the commonest referral and the one where a graded plan is most useful; and periodic re-certification arises in posts, especially **safety-critical roles**, where a standing requirement of demonstrated fitness applies. Each is the same functional question against a different backdrop, and each is answered role by role and moment by moment rather than once and for all.

Two boundaries keep the task honest. The first is confidentiality: the certificate should convey only the conclusion and the work-relevant restrictions and accommodations, not the clinical detail behind them, because the employer has no freestanding entitlement to a person's mental-health information; disclosure needs the person's informed consent or another lawful basis, and only the minimum necessary detail should be released, never a transcript of the consultation. The second is scope: the fitness certificate is an occupational document, and the moment the same clinical picture is wanted as evidence for a court, the exercise becomes expert testimony governed by different duties and treated in the Forensic ethics, consent and legal procedure notes. Likewise, questions of compensation or a disability pension for a work-related psychiatric condition are a distinct assessment with their own purpose and are taken up separately in this chapter; a fitness opinion neither answers them nor should be stretched to.

The honest fitness opinion is modest about what it can promise. It certifies a present capacity for a defined role, hedged by the accommodations that make it workable and by a review date, and it declines to guarantee the future or to pronounce on the person's worth. That restraint is not weakness; it is the whole discipline of the certificate, and it is what keeps a routine signature from doing more legal work than the assessment behind it can bear.

TRAP **Answering a fitness-to-work question with a disability instrument, or vice versa.** The occupational-fitness certificate, the disability certificate that quantifies impairment for benefits, and the expert report for a court are three separate documents with three separate purposes. Borrowing the disability assessment's instrument or threshold to answer whether a person can do a job, or offering a fitness opinion where a court report is wanted, is the classic way to lose an easy mark by producing an authoritative answer to the wrong question.

36 · Workmen compensation and disability pension (psychiatric)

Why the marks are here. A psychiatrist is drawn into compensation and pension work because the law asks a question medicine cannot answer on its own. It does not want to know what the diagnosis is; it wants to know how far the ability to earn has been reduced, and by an injury or illness that some employer or the State is answerable for. This is where clinical description has to be re-expressed in the vocabulary of a statute, and candidates lose marks by answering the medical question when the legal one was asked. The workplace-injury route in India now runs through Chapter VII of the Code on Social Security, which since November 2025 has repealed the Employee's Compensation Act, **1923**, originally the Workmen's Compensation Act and the source of this topic's older name; rights and proceedings that had already accrued under the repealed Act continue under the Code's repeal-and-savings provisions. A disability pension runs through the various service and pension frameworks instead. Employee's compensation centrally uses the statutory concepts of disablement and **loss of earning capacity**; a disability pension uses whatever metric the applicable service or pension scheme prescribes and cannot be assumed to turn on the same idea.

The examinable content is a discipline of translation. The same florid diagnosis can attract a large award or a negligible one depending only on what it does to the person's capacity to work, and

the same clinical picture is weighed differently under a compensation statute, a benefits statute and a pension scheme, because each defines the loss it is buying in different terms. The candidate who can carry a symptom into the language of earning capacity, and keep the three assessments apart, has the marks; the candidate who signs a diagnosis and stops has not.

36.1 The compensable question is loss of earning capacity

The Act does not compensate injury as such. It compensates the economic consequence of injury, the reduction in what the worker can earn, and a diagnosis is only the raw material from which that reduction is worked out. Two employees with the same illness may attract very different awards if one returns to full earning and the other cannot; conversely a modest-looking condition that removes one specific vocational capacity can be economically catastrophic, as when a locomotive driver develops a psychotic illness or a surgeon a disabling tremor. The psychiatric opinion therefore has to end in a statement about the capacity to earn, not in a list of symptoms, and the reasoning that connects the two is the substance of the work.

RULE **Compensation follows the loss of earning capacity, not the diagnosis.** The statute buys the economic consequence of the condition, measured against the work the person could do at the time of the accident. A florid label with preserved earning power attracts little; a contained condition that destroys a particular earning capacity may attract a great deal. The clinician's task is to value the loss, not to name the illness.

36.2 Partial and total disablement under the Act

What follows is now historical law: it describes the repealed Employee's Compensation Act, 1923, retained here because claims and rights that had already accrued before the repeal continue to be decided under it. The repealed Act framed the injury as **disablement** and graded it in two dimensions at once: by how much of the person's working life it removes, and by whether it is temporary or permanent. **Partial disablement**, defined at section **2(1)(g)**, is disablement that, where it is temporary, reduces earning capacity in the employment the person was engaged in at the time of the accident, and, where it is permanent, reduces earning capacity in every employment the person was capable of undertaking at that time. **Total disablement**, defined at section **2(1)(l)**, is disablement, whether temporary or permanent, that incapacitates the person for all work he was capable of performing at the time of the accident. The pivot between the two is the breadth of employment affected, not the visible severity of the injury.

Two deeming provisions convert scheduled injuries into a grade without a fresh enquiry into earning capacity. An injury specified in the second part of the Act's Schedule of injuries shall be deemed to result in permanent partial disablement. Permanent total disablement shall be deemed to result from an injury in the first part of that Schedule, or from a combination of the listed injuries whose loss of earning capacity totals **100%** or more. Outside those deemed cases the grade must be assessed on the facts, and it is precisely there, where no Schedule entry decides the matter, that the psychiatric opinion does its work.

1923	Part I
EMPLOYEE'S COMPENSATION ACT, REPEALED	SCHEDULE I INJURIES, DEEMED PERMANENT TOTAL

The table below sets out the repealed Act's grading structure, retained for historical and pre-commencement reference:

GRADE AND NATURE (REPEALED ACT)	EARNING CAPACITY THAT IS LOST	HOW THE GRADE ARISES
PARTIAL, TEMPORARY	Reduced in the employment the person was engaged in at the time of the accident	Assessed on the facts
PARTIAL, PERMANENT	Reduced in every employment the person was then capable of undertaking	Assessed on the facts, or deemed for an injury in the Schedule's second part
TOTAL, TEMPORARY	Incapacitated for all work the person was then capable of performing	Assessed on the facts
TOTAL, PERMANENT	Incapacitated for all such work on a lasting basis	Assessed on the facts, or deemed for the Schedule's first part or a qualifying listed combination

TRAP **Partial and total are not grades of severity.** They describe the breadth of employment the incapacity spans, not how bad the injury looks. Partial disablement reduces earning capacity in the employment engaged in, or in every employment the person could undertake; total disablement incapacitates for all work the person could then perform. A total disablement can be temporary, and a severe-looking condition can still be only partial. The candidate who reads total as meaning permanent and catastrophic has misread the definition.

The current law replaces this two-by-two structure. Under the Code on Social Security, permanent partial disablement and permanent total disablement are each separately defined and graded, with temporary disablement as its own distinct category rather than a temporary/permanent split within partial and total. The deeming machinery for scheduled injuries and occupational diseases now sits in the Code's own Schedules rather than in the repealed Act's Schedule I, and disputes are decided by a competent authority appointed under the Code rather than by the Commissioner for Employees' Compensation named under the repealed Act. The exact provision numbers are not reproduced here; see the note at the end of this fragment.

36.3 Fitting a psychiatric condition into the framework

The difficulty here is structural rather than clinical. The Act's Schedule was built around visible, measurable physical injury and a list of occupational diseases; it does not enumerate psychiatric conditions or assign them a deemed percentage. A psychiatric sequela, whether a depressive or post-traumatic disorder after a workplace accident, an organic syndrome after a head injury, or an illness said to be occupationally precipitated, therefore almost always falls to be assessed on the general earning-capacity test rather than read off the Schedule. That throws the whole weight of the question onto the clinical opinion and onto its translation into economic terms, which is why this is genuinely psychiatric work and not a clerical signature.

IN INDIA

Because the Schedules assign no deemed figure to a mental illness, a psychiatric claim is decided on the general earning-capacity test, and the dispute over grade and quantum is adjudicated by the competent authority appointed under the Code on Social Security (historically, for claims decided under the repealed Act, the Commissioner for Employees' Compensation). The clinician's report is evidence before that authority, so it has to speak the statute's language, grade of disablement and effect on earning capacity, and not stop at a diagnostic label. A report that names a condition but never reaches earning capacity leaves the adjudicating authority with nothing to convert into an award.

What the report must actually do. A usable opinion carries the reasoning from symptom to earning capacity in steps the adjudicating authority can follow:

- the diagnosis and its expected course, stated plainly and without jargon;
- the specific functional deficits the condition produces, in attention, stamina, reliability, judgement and interpersonal capacity;
- how those deficits bear on the work the person actually did, and on other work they were capable of doing;
- whether the disablement is temporary or permanent, and partial or total, in the statute's sense;
- the causal link between the workplace event and the condition, on which entitlement ultimately depends.

36.4 Impairment, earning capacity and keeping certificates apart

The recurring clinical error is to answer with an **impairment** figure. Impairment measures the loss of function of the person as a whole; loss of earning capacity measures what that impairment does to the ability to work and earn. They are related but not the same, and the Act asks for the second. A hand injury that is a small whole-person impairment is a large loss of earning capacity for a pianist; a psychiatric condition that looks impairing may leave earning capacity in the person's actual field largely intact. The psychiatrist is asked to bridge from the first to the second, using knowledge of the person's occupation, not to hand over a bare percentage of impairment and let the authority guess at its economic meaning.

PITFALL

Certifying a whole-person impairment percentage, or importing the benchmark meant for the disability-rights benefits certificate, when the Act wants an opinion on loss of earning capacity. The two figures are not interchangeable: a benefits threshold answers a different statutory question, and lifting it into a compensation report both overstates and understates the wrong thing. The honest report reasons its way to an earning-capacity opinion rather than borrowing a number designed for another purpose.

Three quite different certificates are commonly conflated, and keeping them separate is half the topic. The statutory disability certificate issued for benefits, reservations and welfare entitlements

under the disability-rights law uses its own instrument and its own benchmark, and certifies disability, not earning loss. The certificate of fitness to resume duty answers whether the person can safely and competently do a job, a forward-looking occupational question. The compensation assessment values a loss of earning capacity already suffered, and a pension assessment values whatever metric, often disablement or impairment attributed to service rather than earning capacity, the applicable scheme prescribes. Each is owned by a different statute and none can be substituted for the others; and where the same clinical picture is wanted as expert evidence for a court or tribunal, that report and the ethics of giving it belong with the Forensic ethics, consent and legal procedure notes.

GOOD TO REMEMBER

Before writing, decide which statutory question you are answering, benefits, fitness to work, or compensation and pension, and use that framework's language throughout. The commonest reason a psychiatric report is sent back is that it answers a different question from the one the form was designed for, and no amount of clinical detail rescues a report aimed at the wrong target.

36.5 Disability pension: a different metric

A **disability pension** is the periodic counterpart to the largely lump-sum compensation of the Act: a recurring benefit for a person whose capacity has been reduced by disability, paid under government service rules, armed-forces rules and various organised-sector schemes rather than under the compensation statute. It raises two psychiatric questions. The first is **attributability**, whether the mental illness is attributable to, or aggravated by, the conditions of service, as opposed to a constitutional illness that would have arisen anyway. The second is the degree of disablement to be recognised. Here the metric often shifts away from loss of earning capacity toward a percentage of disablement or impairment attributed to service, which is why a pension assessment and a compensation assessment of the same patient can reach different figures for entirely defensible reasons.

The precise eligibility thresholds, the rounding conventions, the rules governing attributability and aggravation, and the scheme-specific percentages are fixed by each individual pension framework and are not reproduced here. What the candidate must hold is that these schemes exist, that they turn on a different metric from the compensation statute, and that a compensation percentage must never be carried across into a pension answer, or the reverse. Naming the metric correctly, and refusing to import a figure from the wrong scheme, is what a careful assessment looks like when the exact numbers are set elsewhere.

In any compensation or pension question, translate the psychiatric condition into how far it reduces the capacity to earn, or, for a pension, the degree of disablement attributable to service, and state the grade of disablement, not the label of the illness.

37 · Adoption law and psychiatric fitness of adoptive parents

Why the marks sit here. Adoption pulls the psychiatrist into family law to answer one narrow, statutorily framed question: whether a person proposing to adopt is fit, in mind and in function, to raise a child. Indian law does not leave that fitness to sentiment. It writes it into the eligibility conditions a prospective parent must satisfy, so an examiner can ask for the exact standard, the instrument that sets it, and the clinician's part in evidencing it. The topic belongs with civil and family capacity because adoptive fitness is assessed like any other decision-specific capacity: functionally, at the point of placement, as the ability to take on and sustain the parenting of a particular child, and not as a global verdict on the person's worth.

India runs two parallel routes into a lawful adoption, and what follows covers only one of them in full. Under the Juvenile Justice route, two texts carry the whole of the assessable law. The primary statute is the Juvenile Justice (Care and Protection of Children) Act 2015, whose adoption chapter fixes the fitness conditions for prospective adoptive parents; the working detail is supplied by the Adoption Regulations 2022, framed by the Central Adoption Resource Authority (**CARA**), which turn that standard into concrete eligibility criteria. The Act's own savings clause preserves the second route: an adoption may still proceed under the Hindu Adoptions and Maintenance Act 1956 for a Hindu adopter, and that Act sets its own capacity condition, that the adopter be of sound mind and not a minor, on terms this section does not reproduce. The wider machinery of the Juvenile Justice Act, its care-and-protection provisions, children in conflict with law and the juvenile board, is the province of the Child psychiatry: assessment, treatment, services and protection notes and is not taught here. What belongs to family-capacity law, and to this section, is the fitness of the adopting adult under the JJ Act/CARA route, with the Hindu-law route's own conditions flagged where they diverge from it.

37.1 The statutory architecture: one Act, one delegated code

The reason there are two texts, and the reason examiners test the relationship between them, is that Indian adoption law is built as primary legislation resting on delegated legislation. The Act lays down the mandatory fitness standard for adoptive parents and then, in the very provision that permits a single or divorced person to adopt, defers the operational detail to the adoption regulations framed by the Authority. That Authority is CARA, and those regulations are the Adoption Regulations 2022. The two must therefore be read together: the Act sets the standard and the enabling frame, and the Regulations supply the eligibility gate that a placing agency actually applies. A candidate who quotes one without the other has read only half the law.

IN INDIA

Adoption of a child in need of care and protection runs through the Central Adoption Resource Authority and its recognised specialised adoption agencies, so the fitness standard a psychiatrist may be asked to support is the working gate of that system rather than an abstract test. It is applied in practice through a social investigation and home-study of the prospective parents before a placement is proposed. A psychiatric opinion therefore enters an established administrative process and should be framed to serve it, addressing the statutory conditions directly rather than offering a free-standing character assessment.

37.2 The fitness threshold for adoptive parents (section 57)

The Act's eligibility provision states the core standard in four limbs. A **prospective adoptive parent** *shall* be physically fit, financially sound, **mentally alert** and **highly motivated** to adopt a child for providing a good upbringing. Read the modal verb with the care the examiner will apply. The provision does not say a prospective parent should preferably be mentally alert; it says they *shall* be. This is a mandatory threshold condition of eligibility, not a desirable attribute a placing agency may weigh and waive, and mistaking it for advisory guidance is the fastest way to misstate the law.

Of the four limbs, the psychiatrically load-bearing one is mental alertness, and it is the peg on which a psychiatric opinion is usually hung. The Act deliberately frames it as an active, functional attribute rather than as the absence of any diagnosis. Physical fitness and financial soundness are matters for other assessors; the psychiatrist speaks to whether the person is mentally alert and highly motivated in the sense the statute intends, which is a capacity to engage with and sustain the task of parenting.

MNEMONIC

Fit, Solvent, Alert, Motivated

The four limbs of the eligibility threshold in order: physically **fit**, financially sound (**solvent**), mentally **alert**, and highly **motivated** to give the child a good upbringing. All four are joined by a mandatory "shall", so none is optional.

37.3 The operational eligibility criteria (Regulation 5)

The Regulations sharpen the Act's four adjectives into criteria a placing agency can test. A prospective adoptive parent *shall* be physically, **mentally, emotionally and financially capable**, and two further conditions attach, each carrying its own modal force:

- they *shall* be physically, mentally, emotionally and financially capable of raising a child, which restates the Act's standard as an affirmative capability;
- they *shall not* have any **life-threatening medical condition**, the Regulation's own mandatory wording, read subject to CARA's operational qualification below; and
- they *should not* have been convicted of any criminal act of any nature, nor stand accused in any case of child rights violation.

Note that the modal is not uniform across the three, and the discrimination is examinable. Capability is a mandatory "shall" and the life-threatening-condition clause is a mandatory "shall not", but the conviction-and-accusation clause is worded as a "should not". Reproduce each as the Regulations do rather than levelling them all to a single verb. Read the "shall not" alongside CARA's own standing instructions before calling it an unconditional individual bar: in a couple's application, the Adoption Committee is directed to reject on this ground only where both applicants are affected, weighing medical advice and the other applicant's willingness and capacity to parent, and a controlled lifestyle condition is not on its own a rejection ground; a single applicant's position is assessed on the same functional footing rather than as an automatic exclusion.

RULE **Adoptive-parent fitness is a mandatory statutory condition, not a clinical preference.** Both the Act and the Regulations use the language of duty: the prospective parent must clear the fitness bar for a placement to be lawful. The standard is functional capability to parent, evidenced across the physical, mental, emotional and financial domains, together with the absence of a life-threatening condition, rather than the mere presence or absence of a psychiatric label. The psychiatrist's role is to speak to that functional standard, not to certify normality.

37.4 Who may adopt: consent, couples and the single applicant

Eligibility is not confined to married couples, and the rules on marital status are a favourite of the viva. Where a married couple adopts, the consent of both spouses *shall* be required, so a placement on the wish of one spouse alone is not lawful. A couple is further held to a minimum of relationship stability: no child *shall* be given in adoption to a couple unless they have at least **two years** of **stable marital relationship**, except in the case of relative or step-parent adoption. State that condition with its exception, because the exception is the part candidates drop.

Single applicants are eligible on defined terms. A single or divorced person *may* also adopt, subject to the adoption regulations, and here the enabling verb matters: the law permits it, it does not compel any placement. Within that, a single female *may* adopt a child of any gender, whereas a single male *shall not* be eligible to adopt a girl child. The accompanying table sets the applicants against the rule and its statutory force so the pattern, rather than any isolated phrase, is what is committed.

APPLICANT	ELIGIBILITY RULE	STATUTORY FORCE
Married couple	Consent of both spouses; a minimum period of stable marriage, except in relative or step-parent adoption	Mandatory (*shall*)
Single or divorced person	Permitted to adopt, subject to the adoption regulations	Enabling (*may*)
Single female	May adopt a child of any gender	Enabling (*may*)
Single male	Not eligible to adopt a girl child	Prohibition (*shall not*)

TRAP **Adoption is not restricted to married couples, and a single person is not barred, though the single-male bar is not universal.** Candidates routinely write that only a couple may adopt, or that single applicants are excluded. Under the JJ/CARA route, the law permits a single or divorced person to adopt, and a single female to adopt a child of any gender; the only categorical bar on a single applicant under that route is that a single male shall not adopt a girl child. That bar does not hold across all of Indian adoption law: under the Hindu Adoptions and Maintenance Act, a male may adopt a female child, subject, among the Act's other conditions, to an age gap of at least twenty-one years between them. Flatten either route into "single people cannot adopt", or the JJ/CARA bar into a universal one, and the mark is gone.

37.5 The psychiatric fitness assessment in practice

When a psychiatrist is asked to speak to whether a prospective parent is mentally alert, or mentally and emotionally capable, the question is functional rather than nosological. The statute is not asking for a certificate that the person has never had a mental illness; it is asking whether the person can, in a sustained way, meet the demands of raising the particular child proposed. A stable, treated condition that does not impair parenting is not a statutory disqualifier. The real concern is an untreated or unstable condition that would foreseeably interrupt the safety and continuity of a child's care, which is exactly what the life-threatening-condition exclusion is reaching towards on the physical side.

A useful opinion therefore addresses function and stability, not a label, and covers:

- the applicant's current mental state and its stability over time, rather than a diagnosis considered in isolation;
- the capacity to understand and sustain the demands of parenting the specific child proposed;
- insight, treatment adherence and the support system that maintains stability; and
- any condition that would foreseeably interrupt safe, continuous care.

GOOD TO REMEMBER

A diagnosis is not a verdict. An applicant with a well-controlled mood or anxiety disorder who is stable, adherent and well supported can meet the statutory fitness standard, and writing "unfit" on the strength of a label alone is both poor practice and poor law. Say what the person can do and how reliably, tie it to the mental, emotional and functional criteria the statute names, and reserve an adverse opinion for an impairment that genuinely threatens the child's care.

37.6 Currency, scope and the interface with the court

Two boundaries keep an opinion safe. The first is currency: for the JJ/CARA route, the live framework is the Juvenile Justice Act and the Adoption Regulations 2022 operating through CARA, and Indian adoption regulation has been revised more than once, so an assessment resting on an older adoption guideline is resting on superseded law. The second is scope: the fitness of the adopting adult is the family-capacity question this section owns, while the broader child-protection and juvenile-justice provisions of the same Act, together with the child-protection statutes generally, are taught in the Child psychiatry: assessment, treatment, services and protection notes and should not be folded into the fitness opinion. In the JJ/CARA route,

that opinion feeds an administrative process, not a courtroom one: the adoption order itself is passed by the District Magistrate, not by a court. Court-facing reports arise only where separate litigation, or the parallel Hindu-law route, brings the matter before a judge; the craft of a certificate or report for that setting, its form, duties and confidentiality, belongs to the Forensic ethics, consent and legal procedure notes. Here the psychiatrist supplies the fitness content, not the procedure of whichever forum eventually receives it.

PITFALL

The commonest real-world error is anchoring an opinion to a superseded adoption code, or letting it drift outside the fitness question into the wider child-protection and juvenile-justice provisions that are governed elsewhere. Both make the opinion unsafe. Tie the assessment to the current Act and its Regulations, keep it to the fitness of the adult, and hand the courtroom-certification craft to the notes that own it.

57	5	Two years
JJ ACT: PARENTS' FITNESS	CARA: ELIGIBILITY CRITERIA	COUPLE'S MINIMUM MARRIAGE

Adoptive-parent fitness is a mandatory statutory "shall", set as functional capability to parent and operationalised through CARA's eligibility criteria; the psychiatrist evidences function and stability at the time of placement, never converting a diagnosis into a disqualification.

Violence risk and dangerousness assessment

38 · Concepts of dangerousness and violence risk in psychiatry

Why the marks are here. Few forensic questions reach the psychiatrist as often as the risk of violence. It is asked when a court seeks an opinion before sentence or release, when a review board weighs continued detention, when a ward team decides whether a patient may take leave, and, in ordinary inpatient work, whenever an involuntary admission turns on the harm a person might do to himself or to others. The examiner builds a whole band of questions around it because this is where candidates slip: they answer as though the task were to label a person, when the discipline has spent decades learning that it is not. This section teaches that conceptual footing. It sets out what the older idea of **dangerousness** claimed, why it was abandoned, and what replaced it.

Keep the boundaries of the section in view. The structured instruments that operationalise the modern model, the actuarial tools set beside them, the taxonomy of factors they weigh, and the management of a patient once risk is judged high are each taken up separately in these forensic notes. Here the work is only to get the idea right, because every one of those downstream tasks inherits its logic from the shift described below. A candidate who understands the shift can reconstruct the rest; one who does not will misuse even a good instrument.

38.1 What "dangerousness" meant

The older construct treated the propensity to harm as a fixed personal trait, a stable disposition carried inside the individual and revealed, rather than created, by circumstance. On this view a person either was or was not dangerous, much as he might be tall or short; the environment merely gave the trait its opportunity to show. The idea was legally attractive precisely because it delivered a binary status a court could act on. If dangerousness were a settled attribute of the person, then detaining or releasing him followed cleanly from a single categorical finding, and the psychiatrist could be asked to supply that finding as a matter of expertise.

The construct rested on features that each, in turn, became a reason it fell. It was *dichotomous*: the output was a verdict, dangerous or not, with nothing in between. It was *decontextualised*: because the trait lived in the person, the situation the person was in was treated as incidental. And it was *enduring*: a trait, once present, was assumed to persist, so a finding made today was taken to speak to conduct far into the future. Under this model the clinical task was framed as prediction. The clinician was to forecast whether the individual would be violent, as though violence were an attribute waiting to express itself and the only question were whether the expert could read it in advance. That framing is the one the modern field rejects, and knowing why is the substance of the marks.

38.2 Why the construct failed

The empirical case against dangerousness was blunt. When clinicians predicted it, they were wrong far more often than right, and wrong in a consistent direction: they over-predicted. Cohorts detained as dangerous who were later released by order of a court, and then followed up, went on to serious violence in only a minority of cases, so that most of those held on a dangerousness finding would never have caused the harm the finding forecast. The error was not random noise but a systematic bias toward seeing danger that was not there.

The reason is structural and worth being able to state, because it recurs whenever any rare event is predicted. Serious violence has a low **base rate** in almost any population a clinician assesses. When the event to be predicted is uncommon, even a rule that is accurate most of the time generates a large number of **false positives**, because the handful of people who will truly act are swamped by the many who share the same warning features and will not. A test can look impressive on its hit rate and still, applied to a low-base-rate outcome, flag mostly people who pose no real threat. This is arithmetic, not pessimism, and it does not improve with clinical confidence.

The false positives were not costless. Each was a person detained, stigmatised or denied liberty for a harm he would not have caused, and over-prediction became a respectable-looking route to indefinite preventive detention. There was a second, quieter failure that mattered just as much for practice. Because the danger was located inside the person, the model looked past the circumstances that actually shape conduct, and because it named a fixed trait it offered nothing to do: assessing an unchangeable attribute yields a label and no lever, and gives the clinician no purchase on reducing the very outcome it claims to foresee. The construct thus failed at once

empirically, in its over-prediction; ethically, in the liberty that over-prediction cost; and practically, in the levers a fixed trait denies.

38.3 The reframing: from a trait to a risk

Modern practice replaced the trait with **violence risk**. The change is not merely terminological. Instead of asking whether a person is dangerous, the clinician asks how likely a particular harm is, to whom, how soon, and under what conditions. The newer construct differs from the old in its very form. Risk is *probabilistic*: it is a likelihood, never a certainty, and is properly expressed as a matter of degree rather than a yes or no. It is *contextual*: it is a judgement about a person in a situation, so the same individual may pose a high risk in one set of circumstances and a low one in another. And it is *dynamic*: it rises and falls with time, symptoms and circumstance, so it is a state that fluctuates rather than a settled feature of the person. This single move, from a fixed attribute to a variable, conditional judgement, is the conceptual pivot on which the whole band rests.

RULE **Risk is a state, not a trait.** Violence risk is a probabilistic, contextual and dynamic judgement about a behaviour occurring in a situation, not a fixed property of the person; and because it is a state, the clinical task becomes to assess and manage it, not to predict a status. Every downstream tool and every management plan is an attempt to do that assessment and management well, which is why getting the concept right is prior to getting any instrument right.

The two models can be laid side by side on the axes the examiner tests. Learn the pattern rather than any one row, because viva questions turn on moving from the left column to the right, or on catching an answer that has quietly slid back into the language of the left.

AXIS	DANGEROUSNESS (THE OLDER IDEA)	VIOLENCE RISK (MODERN PRACTICE)
Nature of the construct	A fixed personal trait	A probabilistic, contextual state
Form of the judgement	Dichotomous: dangerous or not	Continuous: a likelihood, along dimensions
Locus	Within the person	The person within a situation
Time course	Static and enduring	Dynamic, varying with time and circumstance
Clinical task	Prediction of a status	Assessment and management of a probability
What it yields	A label or verdict	A formulation with conditions and a plan
Stance to modifiable factors	Nothing to act on	Identifies targets that lower risk

38.4 The anatomy of a risk judgement

Because risk is a probability rather than a verdict, it has structure, and a competent statement makes that structure explicit. A risk judgement is described along **four** dimensions: its nature, meaning the kind of harm feared; its magnitude, meaning how serious that harm would be; its

imminence, meaning how soon it might occur; and its frequency, meaning how often or how repeatedly it is likely to arise. A single global adjective collapses them all into one word and loses the information a decision actually needs, which is why "he is dangerous" tells a court almost nothing while a statement that specifies each dimension tells it a great deal.

What	How bad	How soon	How often
NATURE OF HARM	MAGNITUDE	IMMINENCE	FREQUENCY

The missing element is the condition. Those dimensions describe the harm, but risk is conditional, and the conditions are where the clinical value lies. The same person may carry a high risk under one set of circumstances and a low one under another, so a formulation that omits the circumstances has described only part of the judgement. This is why the modern output is a **risk formulation** rather than a score: it ties the estimated harm to the situations that raise it and the situations that lower it, and it names what follows. A usable risk statement therefore sets out, together:

- the specific behaviour feared, not violence in the abstract;
- the likely target or victim, where one can be identified;
- the circumstances under which the risk rises;
- the circumstances under which it falls; and
- the interventions that follow from the two.

38.5 From prediction to assessment and management

The reframing does more than sharpen language; it changes the job. When risk is understood as a dynamic state, some of what drives it can change over time, and what can change can be targeted. This is why the newer model treats the clinical task as **risk assessment and management** rather than the prediction of a fixed attribute. The point of assessing risk is not to file a forecast but to find the levers, and a construct that admits levers is one a clinician can act on.

The distinction that makes this possible is between the **static** and the **dynamic** drivers of risk. Static considerations are historical and settled, and they anchor the baseline level; dynamic considerations are current and modifiable, and they are what a treatment plan works on. It is the dynamic component that turns a dead-end prediction into a live management task: assess the level and the pattern, identify the modifiable drivers, intervene on them, and reassess, because the estimate is expected to move. The full taxonomy of these factors, static and dynamic, and how they are grouped, is developed separately in these notes and is not rebuilt here; the conceptual point is only that a state, unlike a trait, contains things that can be changed.

The shift also reframes method. The old dangerousness judgement was in practice an unstructured clinical guess, a single expert's global impression, and its poor accuracy was inseparable from its lack of structure. Modern practice replaced that guess with structured approaches, whether the **actuarial** instruments that combine fixed predictors by rule or the **structured professional judgement** that guides the clinician through a defined set of considerations without reducing the decision to a formula. Those methods, and the debate

between them, belong to the separate treatment of risk instruments in these notes; naming them here matters only because they are the machinery through which the reframing is carried out. The management of the violent and high-risk patient, the acute and longer-term plan that acts on the dynamic drivers, is likewise its own section.

38.6 Communicating and acting on risk

A risk opinion is a communication, and its usefulness depends as much on how it is expressed as on how it was reached. The form the modern model demands is conditional and time-limited: it states the assumptions it rests on, ties the estimate to circumstances, gives it a horizon rather than treating it as permanent, and says what would change it. An opinion written that way can be acted on and revisited; a bald categorical label cannot, and it invites exactly the over-detention that discredited the older construct.

GOOD TO REMEMBER

Write a risk opinion the way you would want to read one. Name the specific harm and the circumstances that drive it, put a time horizon on the estimate, and state what would raise or lower it and what you are doing about the modifiable part. "Risk of serious assault is high in the days around contact with his estranged partner and low while that contact is prevented" is a working opinion; "he is dangerous" is a dead end that a court can only over-read or ignore.

IN INDIA

Indian mental health law frames its thresholds in the language of risk of harm to self or to others, not in the older language of dangerousness, and it makes the presence of such a risk a condition for the involuntary route into inpatient care, whose provisions are set out separately in this chapter. The practising psychiatrist meets the concept in two everyday places: in supporting or resisting an involuntary admission, and in medico-legal opinions where a court or authority asks about risk. In both, the reframing is the safeguard, because it obliges the clinician to state a conditional, time-bound judgement rather than to pronounce a person permanently dangerous.

PITFALL

The commonest real-world error is to give a court or a board a categorical verdict, "he is dangerous" or "he is not dangerous", instead of a conditional risk formulation. The first over-detains, because a permanent-sounding label resists any later release; the second falsely reassures, because it strips away the circumstances under which the risk is in fact high. Either way the opinion has smuggled the discredited trait model back in under a modern heading, and it does so most easily when the clinician is asked a yes-or-no question and answers it in kind.

TRAP **Treating "dangerousness" and "violence risk" as interchangeable synonyms.** Candidates use the two words as though they named the same thing and lose the mark the question is testing. They name two different models: one predicts a fixed attribute of the person, the other assesses a probabilistic, contextual and changeable state. An answer that predicts the person rather than the risk-in-context, or that offers a yes-or-no verdict where a conditional judgement is wanted, has answered the older question and earns nothing.

The ethical weight of all this sits just outside the section and should be named, not taught here. A risk opinion can justify preventive detention, and a clinician who learns of a specific, credible threat to an identifiable person may owe a duty that reaches beyond the consulting room; those questions of ethics, confidentiality and the limits of the expert's role belong to the Forensic ethics, consent and legal procedure notes. What this section fixes is the concept those duties operate on.

> Dangerousness asks whether a person is dangerous; violence risk asks how likely which harm is, to whom, how soon and under what conditions, and what changes it. Modern practice, and the examiner, want the second question.

39 · Structured violence risk assessment (HCR-20)

What the marks reward here. Structured violence risk assessment is the discipline of enquiring into the risk of future violence in a fixed, evidence-guided way rather than by global impression, and the examiner who sets this topic almost never wants the internal scoring of any single instrument. What earns the mark is understanding how such an instrument is built, what it is for, and how you would defend the way you used it. The most frequently examined member of the family is the **HCR-20**, and it is the worked example this section is built around. The conceptual groundwork of why a probabilistic, contextual notion of risk replaced the older idea of dangerousness is set out with the account of dangerousness and violence risk in this chapter, and is only leaned on here.

The family is built on a shared shape. First, the assessment is anchored to a fixed list of empirically supported factors, so the clinician cannot simply attend to whatever is salient in the room and quietly overlook a predictor the literature has established. Second, and this is where the methods divide, there is the question of how those listed factors become a conclusion: an actuarial instrument combines them by a fixed statistical rule, while the approach this instrument belongs to keeps the clinician's judgement in charge. Everything that follows turns on that second choice.

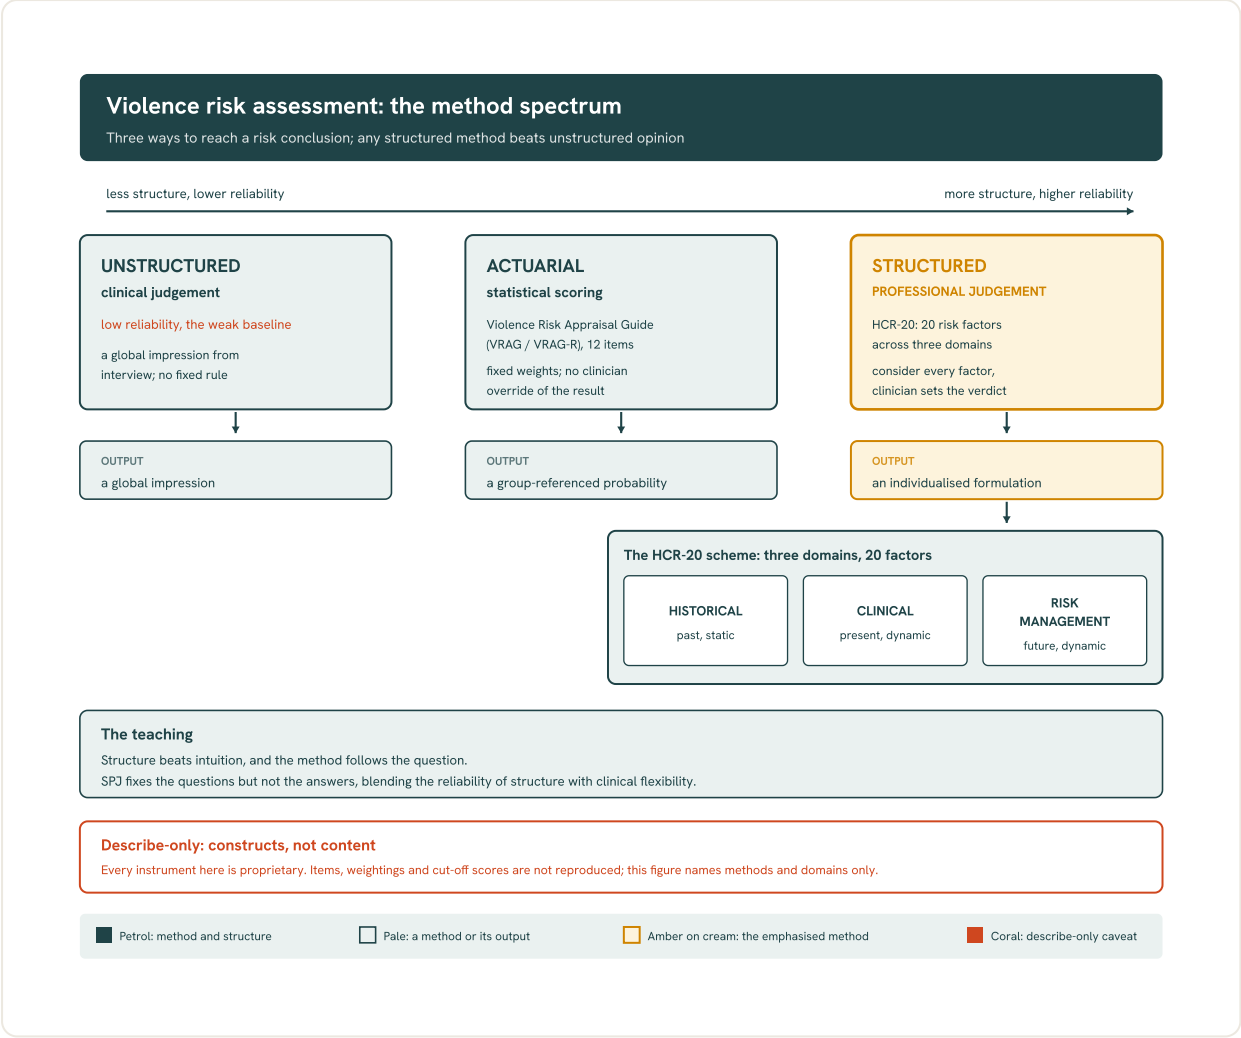

Fig 25.15. Violence risk assessment runs on a method spectrum. Unstructured clinical judgement is the discredited, low-reliability baseline; the actuarial Violence Risk Appraisal Guide (VRAG / VRAG-R) scores fixed weighted items to a group-referenced probability; and structured professional judgement, exemplified by the HCR-20 across its Historical, Clinical and Risk-management domains, fixes the factors that must be considered without pre-weighting them, so it blends the reliability of structure with the flexibility of clinical judgement. Instrument items and cut-off scores are proprietary and are not reproduced.

39.1 Structured professional judgement, and where this instrument sits

Structured professional judgement occupies the middle of a spectrum. At one pole is unstructured clinical opinion, which fixes neither the factors nor the method and predicts weakly; at the other is the actuarial method, which fixes both, combining predetermined and weighted items by a mechanical algorithm and leaving the clinician no licence to depart from the result. Structured professional judgement fixes the questions but not the answer. The instrument specifies the factors that must each be rated and considered, which is its central safeguard against the omission of a known predictor, but the integration of those factors into a risk statement, and the formulation that carries it, remain the clinician's own. The actuarial method itself and the long argument between the two approaches are developed with the account of the other risk tools in this chapter and are only placed here.

The HCR-20 is the exemplar of this method in violence risk work, now in its current third edition. It was developed by **Douglas, Hart, Webster and Belfrage**, and it is a set of professional guidelines rather than a test in the narrow psychometric sense: it directs the assessment without

dictating the verdict. Because it is a copyright-held, proprietary instrument, its manual must be purchased and its item content is not free to reproduce, so a teaching text describes its architecture and purpose and does not print its items. That constraint is returned to below, and it is itself examinable.

RULE **It structures the questions, not the answer.** The instrument ensures systematic consideration of its **20** specified factors, across the whole span of past, present and future, and prompts case-specific formulation; it does not exhaust every possible empirically supported predictor, and it does not convert them into a score. The safeguard is the fixed list; the judgement, the formulation and the final risk category remain the clinician's, which is exactly what makes the method structured and professional rather than actuarial or intuitive.

39.2 The shape of the instrument: the factors and the three domains

The instrument organises violence risk assessment around **20** key risk factors, and it groups them into **three** domains whose initials give the instrument its name: the **Historical** domain, the **Clinical** domain, and the **Risk management** domain. The grouping is not cosmetic. Each domain corresponds to a different tense of the patient's life - what has already happened, how the patient is now, and what is anticipated - so the three together oblige the assessor to look backward, at the present, and forward in one disciplined sweep. An assessment that attends only to a florid mental state, or only to a violent history, has examined one domain and mistaken it for the whole.

MNEMONIC

H, C, R - history, here-and-now, hereafter

The three domains are the three tenses of the assessment. The **H**istorical domain is the settled past, the **C**linical domain is the present state, and the **R**isk management domain is the anticipated future. The name of the instrument is its own contents list.

20	3	SPJ
KEY RISK FACTORS	TEMPORAL DOMAINS	STRUCTURED, NOT ACTUARIAL

Beyond the factors and their grouping, the item content, the coding criteria and the rating anchors are proprietary and are not set out here. The teaching point a candidate must carry away is the architecture - a fixed, comprehensive factor set, arranged by time - and the discipline it imposes, not a reproduction of the coding sheet.

39.3 The three domains and the logic of past, present and future

The value of the domain structure becomes clear when each domain is read for what it contributes to the final judgement. The historical domain gathers the relatively settled features of a life, the record of past behaviour and the long-standing characteristics that shape it, and its function is to anchor the baseline level of concern; being largely fixed, it moves little with treatment and changes slowly if at all. The clinical domain captures the here-and-now, the current state that can shift from week to week, and it is where an assessment registers that a person's risk has risen with a relapse or fallen with recovery. The risk management domain is

prospective: it asks what the future holds for this person, the plans, supports, stresses and supervision that lie ahead, and whether the arrangements around them will contain the risk or inflame it. Read together, a settled baseline, a current state and an anticipated trajectory give a far richer picture than any single snapshot.

This is also where the instrument operationalises the raw material of risk. The historical domain is built largely from static considerations, and the clinical and risk-management domains largely from changeable ones, which is how a fixed factor set nonetheless leaves room for risk to move over time. The full taxonomy of static and dynamic risk factors, and how they are grouped, is developed with the account of the risk factors for violence in mental illness in this chapter and is only named here; the instrument's job is to make sure they are all considered, not to define them.

DOMAIN	TENSE	WHAT IT GATHERS	ITS FUNCTION IN THE JUDGEMENT
Historical	The past	Settled features of the person and the record of past behaviour	Anchors the baseline; largely fixed, so it moves little with treatment
Clinical	The present	The current state and presentation, which can shift over short periods	Registers whether risk is rising or falling now
Risk management	The future	The anticipated situation - plans, supports, stresses and supervision ahead	Asks whether what lies ahead will contain the risk or inflame it

39.4 How an assessment is actually conducted

Structured professional judgement is a method as much as a list, and knowing the sequence is what separates a candidate who can name the instrument from one who could use it. The assessor does not fill in a form but works through a defined order of tasks, and two of those tasks are what give the method its character. One is the weighing of relevance: establishing that a factor is present is only the start, because a factor may be present yet peripheral in one case and decisive in another, and it is the judgement of what it means for this person that an actuarial tool has no equivalent for. The other is the building of a **risk formulation**, an account of what drives this person's risk and how, from which the assessor generates plausible **risk scenarios** - concrete stories of how, when and towards whom violence might occur - before arriving at a summary risk judgement and a plan. Set out in order, the sequence runs:

- establish the presence of each factor from interview, records and collateral information;
- weigh the relevance of each present factor to this individual, not merely its presence;
- integrate the relevant factors into a formulation of what drives the risk;
- generate specific scenarios of how, when and towards whom harm might occur;
- reach a categorical summary judgement and translate it into a management plan.

Why relevance and formulation carry the method. The steps that distinguish this approach from a checklist are the weighing of relevance and the building of a formulation. A checklist stops at presence and tallies it; structured professional judgement insists that presence is only the raw material and that the clinical work lies in deciding what each present factor means for this person and how the factors combine. The output is therefore an individualised, defensible account rather than a number, and the management plan that follows from it, the acting on the changeable drivers the formulation exposes, is taken up with the account of the management of the violent and high-risk patient in this chapter.

39.5 What the method buys, and what it does not

Set against both the unstructured opinion it replaces and the actuarial rule it sits beside, structured professional judgement has a characteristic profile of strengths. Its fixed factor set gives it comprehensiveness, making it hard to forget an established predictor. Because the basis of the opinion is explicit and open to review, it is transparent and defensible. It attends to the changeable and protective features of a case, not only to the fixed historical ones, so the assessment points at what can actually be done. And its output is built for management and communication, a formulation and its scenarios, rather than for prediction alone.

The costs are the other face of these strengths. The method leans on the competence of the assessor: because the judgement is retained, a poorly trained or careless rater can misuse a good instrument, and the reliability an actuarial algorithm delivers mechanically must here be earned by disciplined practice. It is more demanding of time and information than ticking a short actuarial list. And it deliberately declines to produce a probability, yielding a reasoned category and a formulation, not a percentage against a reference group. That structured methods in general outperform unstructured opinion is not in dispute; the finer comparison of accuracy between the actuarial and structured-judgement approaches, and the evidence for each, belongs to the account of the other risk tools in this chapter.

TRAP **Calling this an actuarial instrument, or expecting it to yield a probability.** Candidates group every risk tool together and describe the instrument as though it summed items into a predictive score. It does the opposite: it is a structured professional judgement scheme, and its output is a clinically reasoned category set in a formulation, not a group-referenced probability. An answer that reports a percentage risk, or an actuarial cut-off, from this instrument has misclassified the very method the question is testing.

39.6 A proprietary and restricted instrument

An unusual amount of what a candidate should know about this instrument concerns not its clinical content but its status as intellectual property, and the examiner does test it. The instrument is copyright-held and proprietary. Its manual, the user's guide, must be purchased; it is not a public-domain checklist, and its individual items are not available for licensing, so this resource follows a describe-only editorial policy and does not extract or print them. That the publisher declines to licence items does not by itself settle what Indian copyright law permits for every educational use; applicability turns on the specific use, audience, amount and context, and no categorical legal conclusion is drawn here. Access to the tool is pitched at a restricted

qualification level, on the assumption that a user has the professional training needed to code and interpret it responsibly. These facts explain why every responsible textbook, this one included, names the domains and describes the method but does not reproduce the items or their anchors.

The restriction is not mere legal housekeeping; it guards the instrument against exactly the misuse its structure invites. Because the factors are laid out as a list, an untrained reader is tempted to treat them as a questionnaire to be added up. But the coding of the factors is not a scoring system in the actuarial sense, and the discipline the manual and its training exist to instil is precisely that the number of factors present is not the risk level.

PITFALL

The characteristic misuse is to treat the factor list as a tally and to read a high count of present factors as automatically high risk. That is to smuggle an actuarial habit into a method built to resist it. In structured professional judgement the summary risk category is a clinical integration, what the present and relevant factors mean, taken together, for this person, and not the arithmetic of how many boxes are ticked. A patient with many present factors that are, on formulation, of little current relevance may warrant less concern than one with a few highly relevant ones. Counting the items is not assessing the risk.

39.7 Using the instrument in Indian forensic practice

Two practical realities frame the use of this instrument in India. The first is access: a proprietary, restricted, purchasable instrument is not uniformly available across public forensic services, and its use presupposes training that is not yet widespread, so a candidate should be honest that structured tools of this kind are used unevenly in Indian practice. The second is transfer: unlike an actuarial tool, whose probabilities are only as portable as the sample they were derived on, a structured professional judgement scheme travels comparatively well, because its product is a reasoned, individualised formulation rather than a number tied to a foreign reference group. The structure disciplines the assessment wherever it is used; what does not automatically transfer is any assumption that a given profile carries the same likelihood here as elsewhere.

IN INDIA

Indian courts and authorities tend to ask a categorical question, whether a person poses a risk and whether it can be managed, rather than to ask for a percentage, and that suits a method which yields a reasoned category and a formulation better than one which yields a normed probability. The workable position for the Indian forensic psychiatrist is to use a structured instrument as an aid that disciplines the assessment and makes the reasoning explicit and defensible, to keep its proprietary item content out of any document a lay reader will see, and to treat the categorical, formulated opinion, rather than a borrowed number, as the deliverable. The standards for the report itself and for giving evidence as an expert are set out in the Forensic ethics, consent and legal procedure notes.

GOOD TO REMEMBER

The completed structured assessment is, above everything else, your defensible record. When an opinion on violence risk is challenged, and in forensic work it will be, the worth of having worked through a fixed, recognised factor set is that you can show you systematically considered its **20** specified factors and can point to the formulation that led to your category. Present the domain your concern sits in and the scenario you fear, give a categorical judgement tied to a management plan, and let the structure carry the defence. The acute and longer-term management that plan sets in motion is taken up with the account of the management of the violent and high-risk patient in this chapter.

This is a structured professional judgement scheme, not an actuarial one: it fixes the factors you must weigh across a historical, a clinical and a risk-management domain - past, present and future - then leaves the conclusion, a reasoned risk category set in a formulation, to the clinician. The list is fixed; the judgement is yours.

40 · Other risk tools (VRAG, PCL-R, actuarial versus structured clinical judgment)

What the marks reward here. Structured violence risk assessment is a family of methods, not a single instrument, and the examiner almost never wants the internal scoring of any one tool. What earns the mark is understanding how a tool is built and how you would defend the one you chose. This section sits beside the best-known structured checklist and takes up the other instruments a candidate is expected to name and place: the **actuarial Violence Risk Appraisal Guide**, the clinician-rated psychopathy measure on which so many risk schemes lean, the **Psychopathy Checklist-Revised**, and a dynamic **Short-Term Assessment of Risk and Treatability**. The idea that binds them, and the one the marks are really testing, is the contrast between the actuarial method and structured clinical judgement.

Two questions sit under every risk instrument. The first is how the risk factors are combined into a conclusion: by a fixed arithmetic rule, or by a clinician's disciplined judgement. The second is what that conclusion is for: estimating the probability of a future event, or managing a particular person over time. The actuarial versus structured clinical judgement debate is an argument about the first question, and its modern resolution turns on the second.

40.1 Three ways to reach a risk conclusion

Historically, clinicians judged violence by unstructured opinion: a global impression formed from the interview, with no fixed set of factors and no rule for weighing them. This reads fluently in a report but performs poorly, with weak agreement between assessors and modest predictive validity, and it is the discredited baseline against which every structured method is measured. The actuarial method answered it with the opposite discipline. A fixed set of empirically derived items, each carrying a predetermined weight, is combined by a mechanical algorithm to yield an estimate of risk against a reference sample; the clinician who scores a pure actuarial tool has no licence to override the result. Between these poles sits **structured professional judgement**, which fixes the questions but not the answer: the instrument names the factors that must be

rated and considered, guarding against the omission of a known predictor, while the final risk statement and its formulation remain the clinician's.

The empirical backbone of the actuarial case is older than any of these instruments. Across many fields of prediction it has been found that the mechanical combination of a set of data points tends to equal or exceed the same clinician combining the same information in his head. The lesson carried into forensic work was not that clinicians are useless but that the unaided integration of many weighted cues is a task the human mind does unreliably, while a formula does it the same way every time. That is the argument an actuarial tool cashes out, and it is why a bare clinical impression is no longer a defensible method on its own.

The finding that organises the whole field is remarkably stable across decades of research: any structured method, actuarial or professional judgement, outperforms unstructured clinical opinion. The genuinely open question is therefore not whether to structure the assessment, but which structured method suits the task in front of you.

RULE **Structure beats intuition, and the method follows the question.** Unstructured clinical opinion is the weak comparator that both structured approaches defeat. The choice between actuarial scoring and structured professional judgement is not, then, a contest of accuracy; it is a choice of purpose - a group-referenced probability, or an individualised and manageable formulation.

40.2 The actuarial approach and the Violence Risk Appraisal Guide

An actuarial instrument works the way an insurer prices a policy. Predetermined items are scored from history and records, summed by a fixed formula, and read against tables that link the total to the observed rate of the outcome in the sample the tool was built on. The judgement has, in effect, already been done, by the researchers who derived and validated the weights, and frozen into the scoring. The exemplar in forensic psychiatry is the Violence Risk Appraisal Guide, built by **Quinsey, Harris, Rice and Cormier** from a forensic offender sample. Its current form is a **12**-item actuarial tool, revised in **2013** by **Rice, Harris and Lang** to be simpler to score. Its items and its score-to-probability bands are proprietary and are not reproduced here; what a candidate must carry away is the method, not the grid.

The strengths are the strengths of any mechanical rule: high reliability, transparency, and resistance to the impressionistic biases that sink unstructured judgement. The weaknesses are structural, and worth being able to list, because each is a discussion point:

- the group-to-individual problem, since the output is the rate observed in a reference group and no single person is a rate;
- a reliance on fixed, historical items that do not move with treatment, so the tool is nearly blind to change;
- sample specificity, since the probabilities hold only to the extent that the person resembles the population the tool was derived on;
- silence on protective factors, which are not part of the equation; and

- a design built for prediction, not for the management decisions a clinical team actually has to take.

The taxonomy of static and dynamic factors these tools weigh is developed with the account of violence risk factors in this chapter, and is only named here.

> **PITFALL**
> An actuarial probability is a property of a group, not a verdict on a person. Reporting a percentage risk as though the figure described the individual in the chair is the commonest misuse, and it compounds when a probability derived from a Western forensic sample is applied unmodified to a patient the tool was never normed on. State the estimate for what it is - the rate seen in similar cases, one input to a clinical opinion - and not as this person's settled destiny.

40.3 Structured professional judgement and the START

Structured professional judgement keeps the clinician in the loop by design. The instrument supplies an evidence-based list of factors that must each be rated and considered, which is its central safeguard: it stops an assessor forgetting a factor the literature says matters. It does not then dictate the conclusion. The clinician integrates the ratings, adds case-specific considerations, and produces a categorical judgement, usually low, moderate or high, embedded in a formulation and a set of plausible future scenarios. The best-known instrument of this type is the Historical Clinical Risk Management scheme, whose structure is taken up with the account of structured violence risk assessment in this chapter and is only named here.

A useful contrast within the same family is the Short-Term Assessment of Risk and Treatability, published by **Webster, Martin, Brink, Nicholls and Desmarais** in **2009**. It is explicitly dynamic: its **20** items are the changeable, treatment-relevant features of a case rather than settled history, which suits it to inpatient and rehabilitation work, where the live question is whether risk is rising or falling. Its signature feature is dual coding: every item is rated twice, once as a strength or protective factor and once as a vulnerability or risk factor, so the same domain can be read as an asset or a liability depending on the person. And it is deliberately broad in the outcomes it addresses, spanning not only violence towards others but suicide, self-harm and victimisation as well, so a single rating informs several risk questions at once.

As with the actuarial guide, the manual and its item content are proprietary; the teaching point is the design - dynamic, coded for both strengths and vulnerabilities, and treatability-focused - not the item list.

40.4 The Psychopathy Checklist-Revised and the place of psychopathy

The Psychopathy Checklist-Revised is routinely grouped with the risk instruments, but it is not, in itself, an actuarial predictor of violence. It is a clinician-rated measure of a personality construct, psychopathy, developed by **Robert D. Hare** and published by **Multi-Health Systems**. It is scored from a semi-structured interview together with a careful review of collateral and file information, which is why it cannot be completed from a single consultation and why thin records degrade it. Its items are organised into factors, but the item and factor content, and the

scores at which interpretive labels attach, are proprietary; it is a restricted-user tool that its publisher releases only to assessors holding an advanced degree with specific forensic training. That access restriction is itself an exam-relevant fact, and the reason these contents are named rather than printed in any teaching text.

Why the measure earns a place in a violence chapter is empirical: psychopathy is among the more robust individual correlates of violence and of reoffending, so a psychopathy rating frequently feeds a risk formulation, and several structured and actuarial schemes incorporate it as a component. The discipline to hold onto is that the score measures a construct. It is neither a psychiatric diagnosis nor, by itself, a risk score; it informs the risk judgement and does not constitute it. The three tools map onto the method spectrum as follows.

INSTRUMENT	METHOD CLASS	WHAT IT INDEXES	RATING SOURCE	OUTPUT
VRAG-R	Actuarial	Violence risk	Coded from history and records	Probability against a reference group
PCL-R	Clinician-rated construct measure	Psychopathy	Interview plus collateral and file review	Factor-structured score (proprietary)
START	Dynamic structured professional judgement	Short-term risk and treatability across outcomes	Clinician rating of strengths and vulnerabilities	Categorical risk plus formulation

40.5 Actuarial versus structured clinical judgement

Why the distinction earns marks. A candidate who can only recite instrument names has missed the question; the assessable skill is placing any tool on the actuarial-to-judgement spectrum and saying what that placement buys and what it costs. The contrast is cleanest laid out on shared axes.

AXIS	ACTUARIAL METHOD	STRUCTURED PROFESSIONAL JUDGEMENT
Item selection	Fixed, empirically derived and weighted	Fixed list that must be considered, not weighted
How factors combine	Mechanical algorithm	Clinical formulation
Clinical override	None in the pure form	Judgement is retained
Dominant factor type	Mainly fixed and historical	Historical, changeable and protective
What it yields	Probability against a norm group	Categorical risk plus a formulation
Primary purpose	Prediction and screening	Risk management and scenario planning
Worked example here	The VRAG	The START, and the Historical Clinical Risk Management scheme

The old "clinical versus actuarial" war, fought as though one side had to win outright, is largely settled, and in a way that dissolves the question. Structured methods beat unstructured judgement; that much is not in dispute. Between the two structured methods there is no single victor, because they answer different questions. An actuarial tool is efficient for screening and for anchoring a baseline against a known group rate. Structured professional judgement is built for what happens next: an individualised formulation, attention to changeable and protective factors, and the scenario planning a treating team needs in order to act. Mature practice uses them as complements, and the management of the high-risk patient, which works on the dynamic factors these tools expose, is taken up separately in this chapter.

In everyday forensic work the two methods are less often rivals than layers. A common pattern is to let an actuarial estimate set the baseline, the anchor against a known group rate, and then to adjust that anchor with structured judgement of the changeable and case-specific factors the formula cannot see; this is the so-called adjusted-actuarial approach. What structured professional judgement adds on top of an actuarial floor is incremental: the individualising detail, the modifiable drivers, the protective factors, and the account of the circumstances under which this person's risk rises or falls. Neither layer makes the other redundant, which is exactly why the modern answer to "actuarial or clinical" is "structured, and matched to the decision in front of you".

TRAP **Structured clinical judgement is not clinical intuition.** Candidates see the word clinical inside structured professional judgement, lump it with the discredited unstructured opinion, and then rank the actuarial method as automatically superior. The opposite is the case: structured professional judgement is a rigorous, evidence-guided method, and the weak comparator that both structured approaches beat is unstructured judgement, not each other.

Structure beats unstructured judgement; the actuarial method estimates a group-referenced probability while structured professional judgement builds an individualised, manageable formulation - so you choose between them by the question, prediction or management.

40.6 Using these instruments in Indian practice

Everything above was developed abroad, and that is the practical catch for an Indian forensic psychiatrist. An instrument's validity is not portable by default: it holds only to the extent that the person and the setting resemble the sample the tool was derived and validated on, and the base rates of violence, the completeness of recorded history, and the very questions the law asks all differ here from that context. The tools remain useful, but as structured aids to reasoning rather than as machines that hand down a verdict.

12	20	2009
VRAG-R ACTUARIAL ITEMS	START DYNAMIC ITEMS	START INTRODUCED

IN INDIA

These instruments were derived and normed on Western forensic populations, and none has an established Indian normative base, so their probabilities and interpretive bands cannot be assumed to transfer. Indian courts also tend to ask a categorical question, whether a person is dangerous or fit, rather than for a percentage, and the psychiatrist's reasoned opinion remains central. The workable position is to use these tools as structured aids that discipline the assessment and make the reasoning explicit, not as generators of a number, and to remember that no widely validated indigenous actuarial instrument is in routine use.

GOOD TO REMEMBER

In a forensic report, name the instrument and its method, state plainly that a structured tool informs but does not determine your opinion, and anchor the conclusion in an individualised formulation. Keep the proprietary contents of restricted instruments out of any document a lay reader will see. The standards for the report itself and for expert testimony are set out in the Forensic ethics, consent and legal procedure notes.

41 · Risk factors for violence in mental illness

Risk is read from factors, not from a diagnosis. When a court, a review board or a ward team asks how likely a patient is to be violent, the answer does not turn on the diagnostic label but on a set of identifiable features that raise or lower the probability of harm. Those features are the risk factors, and organising them is the substance of this topic. The reframing that made this the right question - the move from judging a person dangerous to estimating a risk that is probabilistic, contextual and changeable - is set out separately in these notes and is assumed here; the work now is to name the factors that a risk judgement weighs, to sort them in a way that guides action, and to be precise about which of them carry the excess risk seen in mental illness. Examiners return to this ground because it is where careless answers cluster. A candidate who reaches for "mental illness causes violence" has already lost the mark, while one who can separate the fixed markers from the modifiable ones, and can say where the real excess risk sits, has shown exactly the discipline the question is testing.

The factors themselves are the durable content of the field. The instruments that combine them into a structured assessment, the actuarial tools set beside those, and the plan that acts on them once risk is judged high are each taken up in their own right elsewhere in this chapter; here the task is to know the factors, to sort them in a way that leads to action, and to say precisely which of them carry the excess risk that attaches to mental illness. Get the factors right and the downstream machinery has something worth combining; get them wrong and no instrument will rescue the assessment.

41.1 The organising cut: static against dynamic

The single most useful way to hold the risk factors in mind is to ask, of each, whether it can change. On that test they fall into **two** classes. **Static** factors are historical and settled: they belong to what has already happened to a person, or to fixed features of who they are, and no

treatment will alter them. **Dynamic** factors are current and changeable: they are features of the present clinical state and social situation that can rise, fall, or be treated. The classes are grouped this way for a reason that is practical rather than tidy. The static factors tell you how much baseline concern a case warrants; the dynamic factors tell you what you can actually do about it.

Because this cut turns on modifiability, it maps straight onto the clinical task: it separates the part of the assessment that anchors a long-run estimate from the part that a management plan works on and then rechecks. A second, looser way of grouping the same factors is by domain - the person's history, their present mental state, and the circumstances around them. That domain lens is a descriptive convenience, and it is roughly how several structured instruments lay their items out, but it cuts across the static and dynamic division rather than replacing it, and it is the modifiability cut that carries the clinical and the examination weight.

Static	Dynamic	Combined
FIXED HISTORY; SETS THE BASELINE LEVEL OF CONCERN	CURRENT STATE; THE MODIFIABLE TREATMENT TARGETS	ACTIVE PSYCHOSIS WITH SUBSTANCE USE, WHERE RISK CONCENTRATES

41.2 Static (historical) risk factors

Static factors are the fixed history a risk assessment starts from. The most important of them, and the one every scheme places first, is **previous violence**: a documented history of violent behaviour is the strongest single anchor a clinician has for judging future violence. The others in this class share the quality of being settled facts about the person or their past. A young age at the first violent act marks an early-onset, more entrenched pattern rather than a late and situational one. Male sex carries a higher base rate of serious physical violence. And childhood maladjustment - conduct disturbance, abuse, instability and disrupted development in the early years - marks a developmental trajectory that raises the adult baseline. None of these can be shifted by treatment, which is precisely what makes them static: they set the floor of concern, and they do not move.

RULE **Past violence is the best single predictor of future violence.** Of all the factors weighed, a documented history of violent behaviour predicts future violence more strongly than any other, because past behaviour is the most reliable guide to behaviour under similar conditions and because it integrates, in one observable fact, the many influences that a list of separate predictors only approximates. This is why a careful, specific history of any previous violence - its context, its target, its severity and its pattern - is the core of every risk assessment, and why its omission is the most damaging single gap an assessment can carry.

The clinical value of the static factors is exactly their stability. They give a defensible baseline that does not swing with a good phase or a bad one, and they discipline an assessor against being falsely reassured by a calm interview in someone whose history says otherwise. Their limitation is the mirror image of that strength. Because they cannot change, they name no target and offer no lever; an assessment built on static factors alone can estimate risk but can do nothing to reduce it. That is the work the dynamic factors do.

41.3 Dynamic (changeable) risk factors

Dynamic factors are the current, modifiable features that raise or lower risk from week to week, and they are where the clinical yield of the whole assessment lies. The first group is the patient's active symptoms, and not all symptoms carry risk equally. The ones that matter are those that make violence feel, to the patient, necessary or externally driven. **Threat or control-override symptoms** - the belief that one is under threat from others, or that an outside force is overriding one's own control, as in delusions of passivity or of thought and behaviour being imposed - are the psychotic experiences most consistently linked to violence, because they recast an assault as self-defence or as something one is compelled to do. **Command hallucinations**, especially those instructing harm in a voice the patient feels unable to resist, work in the same way. It is the content and the felt compulsion of the symptom, not the diagnosis it sits within, that raises the risk.

Beyond the symptoms, several further dynamic factors recur. **Substance misuse** is among the most powerful of all, and its particular role in mental illness is considered further when the excess risk is discussed below; the clinical management of a substance use disorder itself belongs to the Substance use disorders notes. **Treatment non-adherence** - stopping medication, disengaging from services, missing the very contact through which deterioration would be caught - both reflects and drives rising risk. And social instability, meaning the loss of housing, occupation, supervision and supportive relationships, strips away the external structure that contains behaviour and amplifies the effect of everything else. Each of these can be targeted, which is why they, and not the settled history, are the material a management plan actually works on.

41.4 Setting the two classes side by side

The distinction is worth laying out on shared axes, because the examiner tests movement across the columns and because the two classes differ in almost everything except that both predict. Learn the pattern rather than any single row, and notice that the difference in modifiability is what drives every other difference below it.

AXIS	STATIC (HISTORICAL)	DYNAMIC (CHANGEABLE)
Nature	Settled facts of history and person	Current clinical state and circumstance
Modifiability	Fixed; unchanged by treatment	Modifiable; the targets of treatment
Typical members	Prior violence, early age at first violence, male sex, childhood maladjustment	Threat and control-override symptoms, command hallucinations, substance misuse, non-adherence, social instability
What they anchor	The long-run baseline level of concern	The current, near-term direction of risk
Clinical use	Screening and baseline estimation	Intervention, monitoring and reassessment
Limitation	Name no target to act on	Fluctuate, so demand repeated review

A closing word on the domain lens keeps it from becoming a third scheme to memorise. Grouping factors as historical, clinical and contextual describes where a factor comes from, not whether it can change, so a single domain holds both kinds: the historical domain is largely static, while the clinical and the contextual domains are where the dynamic, movable factors sit. Used together, the domain lens makes sure no source of information is overlooked, and the static and dynamic cut keeps sight of what can actually be done about what is found.

41.5 Where the excess risk sits in mental illness

The label is not the risk factor. The single most examined point in this topic is also the most misunderstood in public life: a psychiatric diagnosis, taken by itself, is a poor guide to violence. The excess risk that genuinely attaches to mental illness is not spread evenly across all patients or all conditions. It is concentrated in active psychosis complicated by co-occurring substance use, and it is carried by particular symptoms rather than by the diagnostic category. A person with a stable, treated illness and no substance use stands in a wholly different place from one in an untreated psychotic relapse who is also drinking or using, even under the same diagnostic heading.

The concentration comes from the active psychotic state and from substance use, acting together. Within the psychotic state the risk is carried by the specific symptoms already named: the sense of being threatened or of having one's control overridden, and commands that feel impossible to resist. These are features of a current relapse, not of the diagnosis in remission, which is why risk tracks the state and falls when the state is treated. Substance use raises risk by several routes at once - disinhibition and intoxication, the destabilising of an underlying illness, worsened adherence, and the social chaos that surrounds dependence - and its effect is more than additive when it sits on top of an active psychosis. It is the meeting of the two, far more than either alone and far more than the label, that accounts for most of the elevated risk clinicians actually meet.

TRAP **Naming the diagnosis as the risk factor.** Asked for the risk factors for violence in mental illness, candidates write "schizophrenia" or "psychosis" as though the diagnostic label were itself the factor. It is not. The risk is carried by an active symptomatic state - threat and control-override symptoms, commands that feel irresistible - and, above all, by co-occurring substance use, not by the diagnosis in the abstract. An answer that indicts the category rather than the state has lost the mark and repeated the very stigma the evidence corrects.

PITFALL

The mirror-image clinical error is to build the whole assessment on the static history - previous violence, sex, early onset - because it feels objective and countable, and to record the current state only in passing. Such an assessment can produce a plausible baseline and still be useless, because it names nothing that can be changed and so leads to no plan. The static factors tell you how worried to be; only the dynamic factors tell you what to do, and an assessment that neglects them predicts without managing.

In mental illness the excess risk of violence sits in active psychosis with co-occurring substance use, not in the diagnostic label; and across all cases previous violence remains the single strongest predictor.

41.6 From factors to formulation, and to practice

Risk factors are inputs, not conclusions. Counting them does not yield a risk level; they are weighed and combined, either by a fixed actuarial rule or through structured clinical judgement, into a formulation that ties the estimated harm to the circumstances that raise and lower it. The structured instruments that carry out that combining, such as the **HCR-20** and the **VRAG-R**, operationalise the very factors set out here, by structured clinical judgement and actuarial method respectively; their internal structure, and the actuarial-versus-judgement debate, are taken up in their own right elsewhere in this chapter and are only named here. The **PCL-R** measures psychopathy rather than combining this taxonomy into a violence-risk conclusion; it may inform a formulation or appear as a component within another instrument, but it is not itself a combining violence-risk tool. A full formulation also weighs protective factors - the supports, engagement and stability that lower risk - which a bare factor count leaves out; these too are named here and are developed with the instruments that code them.

Turning the taxonomy into an actual assessment means eliciting each class deliberately rather than hoping it surfaces. In practice that means covering, for every case:

- a detailed history of any past violence, including its context, target, severity and pattern, as the strongest single anchor;
- the current mental state for threat and control-override symptoms and for commands the patient feels unable to resist;
- current substance use, screened in every case and never assumed to be absent;
- engagement and adherence with treatment and services; and

- the stability of housing, occupation, supervision and close relationships.

The static items anchor the baseline; the dynamic items, being the modifiable ones, become the targets of the plan whose acute and longer-term forms are set out separately in this chapter. The point of sorting factors this way is never the sorting itself. It is that a formulation which ends with a set of dynamic targets can be acted on and revisited, while one that ends with a static score can only be filed.

IN INDIA

The factor taxonomy itself travels well - previous violence, active psychosis, substance use and social instability raise risk everywhere - but the instruments that weigh these factors were derived and normed on Western forensic populations and have no established Indian base, so their probabilities and cut-offs cannot be assumed to transfer. Indian practice therefore leans on the factors themselves, appraised through structured clinical judgement, more than on any actuarial score. Local realities shape the dynamic factors in particular. The family remains the main structure of supervision and the main route back into treatment, so involving it is often the most powerful modifiable protective factor available; and gaps in access and continuity of care make treatment non-adherence a live and common driver of relapse and of rising risk.

GOOD TO REMEMBER

A risk assessment that records the diagnosis and the past history but not the current dynamic state has captured the least changeable part of the picture and missed the part you can treat. Make it routine, in every case, to document the active symptoms that carry risk, to screen for co-occurring substance use rather than assume it, and to check adherence and social supports - and then, for each dynamic factor you find, to name what you intend to do about it. That is what turns a list of factors into a plan.

42 · Management of the violent and high-risk patient

Why the marks are here. The acutely violent or agitated patient is one of the few situations in psychiatry where a clinical decision and a legal act are the same act. Every step taken to make a ward safe, from a word to an offered tablet to an injection given without consent to a hand laid on a patient, runs from ordinary care toward the deprivation of another person's liberty, and the law watches the far end of that line closely. The examiner builds a whole question here because candidates who can recite risk factors and name instruments often come apart on what actually matters at the bedside: what to do, and in what order. This section teaches that answer, the graded response to acute disturbance and the longer-term work that follows once the emergency has passed.

Two ideas hold the topic together. The first is that management is *graded*: interventions are ranked by how far they override the patient's own choices, and you exhaust the less coercive before reaching for the more coercive, escalating only as far as safety requires and stepping back as soon as it allows. The second is that management runs across *two horizons* at once: the acute horizon of the next several minutes, where the task is to contain disturbance and prevent

immediate harm, and the longer horizon of weeks and months, where the task is to lower the risk that produced the episode. Answer only the first and you have described a scuffle; answer only the second and you have left a dangerous situation unmanaged.

RULE **Use the least coercive measure that will keep people safe, and no more.** Acute management climbs a ladder: environmental and verbal measures first, then medication offered and taken by choice, and only where safety demands it and the law permits, coercive sedation and physical control. Each rung is justified by the failure of the one below it, never by disruption or convenience, and you climb down the moment the danger falls.

MNEMONIC

Talk, offer, tranquillise, restrain

The four rungs of acute management, in order. **Talk** the situation down; **offer** medication the patient can accept by choice; **tranquillise** by injection only if talking and offering have failed and danger remains; **restrain** physically, only as a lawful last resort to prevent imminent harm. Seclusion and solitary confinement are prohibited outright in India and are never a rung on this ladder.

42.1 The graded ladder of acute intervention

The options are arranged as a ladder because coercion is a harm in itself: the burden of justifying each step rises as the step takes more of the patient's autonomy, so the least restrictive measure that will work is always the right place to start. The examiner tests movement between the rungs and the reasoning that carries you from one to the next, which the table lays out.

RUNG	WHEN YOU REACH FOR IT	WHAT IT AIMS AT	THE SAFEGUARD IT DEMANDS
Environmental and verbal de-escalation	First, in every case of acute disturbance, and continued throughout	Lowering arousal so the patient regains control and coercion becomes unnecessary	None beyond good practice, because it overrides no choice
Offered oral medication	When talking alone is not settling the patient	Relief of distress and agitation, taken by the patient's own consent	A genuine choice, since it is help offered and not force applied
Rapid tranquillisation	When de-escalation and offered medication have failed and danger persists	Calming enough to reduce risk and permit care, not sedation into unconsciousness	Given under necessity, with physical monitoring afterwards
Physical restraint	The last resort, when less restrictive measures cannot contain a risk of harm	The immediate physical safety of the patient and of others	Lawful only within the statutory limits set out elsewhere in this chapter, which permit physical restraint but ban seclusion outright

Reading down the last column shows the logic: each higher rung takes more of the patient's liberty and demands more justification.

42.2 De-escalation: the mandatory first line

De-escalation is the coordinated use of environmental and interpersonal measures to bring down a patient's arousal and help them recover their own control, so that no more coercive measure becomes necessary. It is not a soft preliminary to the real work; it is the first line of treatment for acute disturbance, attempted in every case and continued even while more coercive options are prepared in case it fails.

Its two arms are worth separating, because a candidate who names only the talking has described half of it. The **environmental** arm reshapes the situation the disturbance is happening in: reduce the stimulation and noise, remove the audience a frightened patient may be performing to, take away objects that could become weapons, and ensure there is space, a clear exit for patient and staff, and enough staff nearby that no one is trapped. A visible but unthreatening staff presence signals that the situation is contained without becoming a confrontation. The **interpersonal** arm is the manner of the person who engages: one clinician leads so the patient is not surrounded by competing voices, keeping a calm posture and tone, respecting personal space, and avoiding threats, ultimatums and any display that reads as a challenge. The aim is not to win an argument but to lower the temperature.

Much of what settles an agitated patient is the acknowledgement of a real grievance and the meeting of an unmet need. A patient may be agitated because they are in pain, frightened, thirsty, needing the toilet, or waiting without information, and a clinician who listens, names the distress and offers realistic choices restores a sense of agency. Practical verbal measures that repay learning include:

- letting the patient speak and signalling that their distress has been heard;
- speaking simply and slowly, in short sentences, without jargon or threats;
- offering realistic choices so the patient keeps some control of what happens.

42.3 Offered medication: the collaborative step

When talking alone is not settling the patient but the situation is not yet an emergency of imminent harm, the next rung is medication offered and taken by consent. The distinction between medication a patient accepts and medication imposed on them is not a technicality; it is the whole difference between collaboration and coercion. A patient who takes an oral medication offered as relief from distress has not been overridden at all, and their autonomy is left intact. Offering the choice, explaining that it is there to help rather than to control, and where possible giving some say in the form, keeps the encounter therapeutic rather than adversarial.

The specific agents and doses at this step are clinical-protocol matters this section does not fix; the reasoning the examiner wants is the principle. Where a patient will accept oral medication, that acceptance is preferable to any imposed alternative even when the imposed alternative would act faster.

42.4 Rapid tranquillisation: calming under necessity

When de-escalation and offered medication have failed and the patient remains an immediate danger to themselves or others, this does not by itself authorise treatment without consent:

where the Mental Healthcare Act's emergency-treatment provision is satisfied, necessary parenteral medication may be given under that provision to bring the disturbance under control, subject to its professional, consent, seriousness, purpose and duration limits, and otherwise the applicable treatment-consent provisions continue to govern. This is **rapid tranquillisation**, and its purpose is precise and easily misstated. The aim is to calm the patient enough to reduce the risk and allow assessment and treatment to proceed; it is not to sedate them into unconsciousness. An answer that describes the goal as knocking the patient out has misunderstood the intervention and the standard it is held to.

Because it is a treatment imposed without consent, rapid tranquillisation carries the same requirement of justification as any coercive act: it is used only where it is necessary for safety and the less restrictive rungs have not sufficed. It also carries genuine physical risk, and a sedated patient cannot simply be left, because over-sedation must be caught early. In broad terms the responsible clinician attends to:

- the level of consciousness and the depth of sedation against what was intended;
- the airway, breathing and circulation, which sedation can compromise;
- the patient's basic physical observations until they have recovered.

The exact agents, doses, observation intervals and escalation thresholds are protocol specifics this section does not assert. The frame it does assert is a calming aim not an obliterating one, a necessity justification not a convenience one, and mandatory physical monitoring of a chemically sedated patient.

TRAP **Jumping to rapid tranquillisation or restraint as the first move.** Under the pressure of a violence scenario candidates skip straight to the injection or the restraint team, and the examiner reads that as not knowing the graded approach. De-escalation is the first line in every case and is what a correct answer opens with; medication offered by consent precedes medication imposed; and coercive measures are justified only by the failure of the less coercive ones and by a genuine risk of harm. Naming the top of the ladder first, or omitting the rungs below it, loses the marks the question is built around.

42.5 Physical restraint, and the outright ban on seclusion

Physical restraint, the manual or mechanical holding of a patient, is the most restrictive measure the law still allows and therefore the last rung on the ladder. It is used only when the measures below it have failed or are inadequate and a risk of harm cannot otherwise be contained. **Seclusion**, the supervised confinement of a patient alone in a room they may not leave, is a different matter: in India it is not a bounded last resort at all but is prohibited outright, so it never appears on this ladder. Physical restraint, by contrast, is not merely a clinical decision; it is bounded by statute, where the clinical answer and the legal answer meet.

IN INDIA

The Mental Healthcare Act **2017** governs restraint and seclusion, and it draws a hard line between them. Its section **97**, set out in full with the prohibited and restricted procedures elsewhere in this chapter, prohibits seclusion and solitary confinement of a person with mental illness altogether. Physical restraint alone is conditionally permitted, and only where it is the sole means available to prevent imminent and immediate harm to the person or to others, only when authorised by the psychiatrist in charge, kept time-limited and recorded, and never used as a punishment or for the convenience of staff. The clinical decision to restrain therefore lives inside a statutory frame; to seclude a patient at all, however well meant, is unlawful, and restraint that steps outside those bounds is unlawful as well as poor practice.

Translated into practice, those bounds mean physical restraint is chosen only when nothing less will do, kept to the shortest duration the danger requires, held under continuous review, and ended the moment the risk has fallen. The patient is not abandoned to the measure: their physical safety is observed throughout, and the episode, its justification, duration and review, is documented contemporaneously. Its justification lasts exactly as long as the harm is imminent, and no longer.

PITFALL

The characteristic real-world failure is physical restraint used for the ward's convenience rather than the patient's safety: to manage staffing, to quieten a disruptive but not dangerous patient, or as an unspoken sanction for difficult behaviour, then left in place longer than any imminent risk warrants and poorly recorded. Each of these steps outside the statutory limits, which permit physical restraint only to prevent imminent harm, only as the sole means available, and only time-limited and recorded. Reaching for seclusion is a failure of a blunter kind, because seclusion is banned outright and is never a lawful option to begin with. Using restraint where there is no imminent risk, or continuing it past the point of danger, converts a lawful safety measure into an unlawful one.

One further boundary should be named and not taught here. When the assessment of a violent patient turns up a specific and credible threat to an identifiable other person, the duties that may then follow, the questions of confidentiality and of any duty to protect a third party, belong to the Forensic ethics, consent and legal procedure notes.

42.6 The longer horizon: targeting the modifiable drivers

Why the second horizon carries the marks. Containing an acute episode does nothing about the reasons it happened; a patient calmed today who returns to the same drivers will be back tomorrow. Longer-term management is therefore a change of task, from containing disturbance to lowering the probability of recurrence. The lever is the distinction between the drivers of risk that cannot be changed and those that can: the historical, static factors anchor a patient's baseline, while the modifiable, dynamic factors are what a treatment plan works on. The full taxonomy of these factors is developed in the separate treatment of the risk factors for violence

in mental illness in these notes rather than rebuilt here, and longer-term management is in essence the systematic pursuit of the **modifiable risk factors**.

Treat	Address	Support	Structure
THE UNDERLYING ILLNESS	SUBSTANCE USE	ADHERENCE	THE FOLLOW-UP

Each of these targets a driver that can actually move. **Treating the underlying illness** comes first, because active symptoms are themselves dynamic drivers of risk, and the effective treatment of a relapsing psychosis or a manic episode removes one of the strongest levers on the patient's dangerousness. **Addressing substance use** matters because intoxication and dependence are among the most powerful modifiable contributors to violence; the clinical treatment of substance use disorders and the pharmacology of de-addiction are covered in the Substance use disorders notes, and a violence-reduction plan which ignores a patient's substance use has left its most tractable driver untouched.

Supporting adherence follows directly, because the treatment that lowers risk only does so while the patient is actually receiving it, and disengagement or covert non-adherence is often the first step back toward relapse and the risk that comes with it. Attending to the therapeutic alliance, to side effects that drive patients away from their medication, and to the practical barriers to staying in treatment is part of managing risk, not separate from it. **Structured follow-up** ties the rest together: assertive engagement, a clear care plan, the monitoring of the dynamic factors, and a crisis plan for the situations known to raise this patient's risk. Because the modifiable drivers change with time, the plan is reviewed rather than written once, and the structured risk assessment covered separately in these notes is the instrument through which that review is kept honest.

42.7 The record and the review

Two practices run through the whole of management and are examined as competence, not paperwork. The first is **documentation**: a coercive decision that is not recorded cannot be shown to have been justified, proportionate, time-limited or reviewed, and where each step overrides a patient's liberty the record is the evidence that the law's conditions were met. The second is the **post-incident review**. After a serious episode, the event is reviewed for the patient, whose experience of being restrained or sedated needs understanding and whose care plan may need revising, and for the staff, whose safety and learning bear on the next episode. A ward that manages violence well de-escalates first, coerces only within the law when it must, and learns from each event.

GOOD TO REMEMBER

Two habits separate safe management from lucky management. In the acute phase, your manner and the environment are the first instrument, not the prescription pad, and if you do sedate, keep watching the patient's breathing rather than assuming the job is done. The work does not end when the patient settles: review the episode with patient and staff, then turn the care plan to the drivers that can be changed, because that is where the next incident is prevented.

Manage the violent patient by climbing the least-coercive ladder first, de-escalation, then medication offered by consent, then rapid tranquillisation only to calm and not to sedate into unconsciousness, and physical restraint only as a lawful last resort to prevent imminent harm, seclusion being prohibited outright in India; then lower future risk by treating the illness, addressing substance use, supporting adherence and structuring the follow-up.

Cross-cutting synthesis

43 · Cross-cutting synthesis

Why this synthesis earns its own place. Every other section in this chapter teaches one rule and then closes; this one shows how those rules interlock. Read alone, the Mental Healthcare Act, the disability legislation, the narcotics law, the tests of criminal responsibility, the civil and family capacities and the assessment of violence risk look like a list of unrelated statutes a candidate must memorise in parallel. They are not unrelated. The chapter has two spines - the legislation a psychiatrist practises inside, and the questions a court puts from the outside - and a single construct runs the length of both and holds them together. That construct is **capacity**, and learning to see it is what turns a dozen separate topics into one subject.

The reason it matters for the marks, and for the ward, is that capacity is almost never the global, once-settled attribute that everyday language implies. It is asked of a particular decision, and it is asked at a particular time. The same patient, on the same afternoon, can have the capacity the law requires for one decision and lack it for another; and a person who lacked it a month ago may have it today. Miss either property and the whole architecture collapses into the error the examiner is watching for - reading one capacity off another, or fixing a person's capacity as a permanent fact of who they are. This section re-teaches no single test. It names each in a clause, cross-refers it to the topic that owns it, and then does the one thing no other section can: it lays the tests side by side so the shared logic shows.

Which decision?	Which moment?	Which forum?
CAPACITY IS DECISION-SPECIFIC	CAPACITY IS TIME-SPECIFIC	COURT, BOARD OR WARD

43.1 One construct beneath two spines

Set the chapter out as its architects did and the shape becomes easy to hold. The first spine is the mental health legislation a psychiatrist works within: the Mental Healthcare Act with its definition of illness and its consent, admission and review machinery; the Rights of Persons with Disabilities Act with its certification and guardianship; and the narcotics law. The second spine is the run of forensic questions a court asks from the bench: was the accused responsible for the act, is a person competent to make a will, a contract or a marriage, is the accused fit to be tried, and does this patient pose a risk the law must weigh. The two spines are usually taught, and examined, apart. What binds them is that every question on either spine is, when you reach its base, a question about whether a specified person could make a specified decision. The legislation asks it

in order to protect and to empower; the court asks it in order to attribute or to withhold responsibility. The asking is the same act.

Because the seam is a single construct, the sections interlock rather than merely sit next to one another. A treatment refusal on the ward and a disputed will in a civil court are the same question - can this person make this decision - wearing different robes. Once that is seen, the statutes stop competing for memory and begin to reinforce it: recall the seam, and each provision hangs off it in its proper place. The rest of this section develops the two properties that make the seam behave the way it does, lays the capacities on a common grid, walks a single case across the handoffs it must cross, and shows how one judgement is read differently depending on who receives it.

43.2 The same patient, several decisions

The first property is that capacity is **decision-specific**. It is not a global competence a person carries about with them; it attaches to the decision in front of them, and it can be present for one and absent for another at the very same moment. The Mental Healthcare Act's treatment-decision capacity asks only whether the patient can make the mental-healthcare choice at hand; it says nothing about whether the same patient can make a will. **Testamentary capacity** asks whether the person grasps the nature of the act of making a will and the claims they ought to weigh, a standard taught in full in this chapter's topic on will-making capacity. **Contractual capacity** asks whether, at the point of contracting, the person was of sound enough mind to understand the bargain and judge its effect on their interests, which is a different topic again. **Criminal responsibility** asks whether unsoundness of mind at the time of an act should excuse it. Each is its own test, owned and set out in its own place in this chapter; none is a proxy for the others.

That they can diverge in the same person is not arbitrary but structural, because each decision makes a different demand. A will requires a person to hold in mind the extent of their property and the people with a claim on it; a consent to treatment requires them to weigh a foreseeable benefit against a foreseeable harm over a shorter horizon; a contract requires them to appraise an exchange and its consequences for their own interests. A delusion that fixes on the natural beneficiaries of an estate may destroy the capacity to make a valid will while leaving the capacity to consent to an injection wholly intact, and a fluctuating confusional state may remove the capacity to weigh a complex financial bargain while leaving a simple, well-rehearsed treatment choice within reach. So the answer for one decision genuinely does not settle another, and an opinion that a person "lacks capacity", full stop, is not an opinion at all until it names the decision it is about.

43.3 The same decision, a specified moment

The second property is that capacity is **time-specific**. It is judged as at a moment, not for a lifetime, and the moment the law fixes on differs for different questions - which is the single most consequential distinction in the whole chapter. Treatment-decision capacity is assessed when the decision must actually be made, and reassessed as the patient's state changes, because a person too disturbed to decide on admission this week may be well able to decide on discharge the next.

The capacity to make a valid will is judged as at the time the will is executed; the capacity to contract as at the time of contracting. And the forensic pair pulls furthest apart on precisely this axis: criminal responsibility is judged as at the time of the act, while **fitness to stand trial** is judged as at the time of the trial, which may fall months or years later and in a quite different mental state.

That gap is where careful candidates separate themselves from careless ones. A man may have been floridly psychotic when he killed and have recovered entirely by the time he is arraigned: responsible-or-not is answered by his mind at the act, fitness by his mind in the dock, and the two answers can point in opposite directions without any contradiction between them. The mirror case is just as real - a person sane at the time of an act may become unfit to be tried through an intervening illness. Because capacity moves in time, every forensic and civil opinion is anchored to a date and to a decision, and an assessment reported without its moment is incomplete in exactly the way an assessment reported without its decision is.

43.4 The capacities on one grid

Laying the capacities on shared axes is the payoff of treating them as one subject rather than five. The grid below restates no test - each is taught where it is owned - but sets each against the same three columns: the decision it governs, the moment at which it is judged, and who puts the question and answers it. Read down any column and the family resemblance is plain; read across any row and the test's own distinctness is preserved.

CAPACITY IN ISSUE	THE DECISION IT GOVERNS	WHEN IT IS JUDGED	WHO PUTS AND ANSWERS THE QUESTION
Treatment-decision capacity	Consent to, or refusal of, mental-healthcare and treatment	When the decision must be made, and again as the state changes	The treating clinician under the Mental Healthcare Act, open to the Review Board
Testamentary capacity	Making a valid will	As at the time the will is made	A civil court, on the will-making standard
Contractual capacity	Entering a binding contract	As at the time of contracting	A civil court, on the soundness-of-mind standard
Criminal responsibility	Whether unsoundness of mind excuses the act	As at the time of the act	The criminal court
Fitness to stand trial	Whether the accused can take part in the trial	As at the time of the trial	The criminal court

The grid makes one lesson unavoidable, and it is the rule to carry out of this section.

RULE **Capacity is decision-specific and time-specific - it is asked of one decision at one moment, never of the person in general.** A finding for one decision does not carry to another, and a finding at one time does not carry to another. So an assessment is complete only when it names both coordinates: which decision it is about, and as at which moment it speaks. Anything shorter - "the patient has capacity", or "the patient lacks capacity" - is not yet an opinion the law can use.

43.5 The handoffs a single case crosses

A real case does not stay in one box; it hands the same person from one capacity question to the next, and often from one forum to another. Watching a single patient move through the chapter is the surest way to feel how the sections interlock in practice rather than only on a grid.

- An admission decision turns first on treatment-decision capacity: whether the patient can make the admission and treatment choice themselves decides whether they are admitted on their own request or through the supported route, a determination the Mental Healthcare Act governs and the Review Board can later be asked to examine.
- A capacity question can become a **guardianship** question: where the inability to manage one's affairs is enduring rather than momentary, the issue shifts from a single bedside decision to the appointment of someone to decide across a domain of life, under the disability legislation's limited-guardianship route or the general property-management machinery, each taught in its own place here.
- A criminal act raises two capacity questions at once: responsibility, fixed as at the time of the act, and fitness, fixed as at the time of the trial - the same accused, two separate inquiries that must not be run together.
- A consent-to-treatment moment can recur inside the forensic pathway: a patient found unfit, or detained after a verdict, still has treatment decisions to be made, and a treatment such as electroconvulsive therapy re-poses the consent-and-capacity question the Act governs, while the clinical technique of that treatment belongs to the ECT and neurostimulation notes.

TRAP **Answering the responsibility question with evidence of the trial-time state, or the fitness question with evidence of the state at the act.** The two inquiries share an accused and a diagnosis, so a candidate under pressure fuses them and describes the mental state at the one moment they can most easily picture. But responsibility looks back to the act and fitness looks to the courtroom now, and the states at those two moments can be wholly different. Keep the clock, not the person, at the centre: name which moment the question fixes on before you describe any mental state.

Two boundaries are worth marking as the case crosses them. When the forensic frame touches a child - a custody dispute, or a juvenile whose case raises a preliminary assessment - the governing child-protection statutes are named here and taught in the Child psychiatry: assessment, treatment, services and protection notes, and are not reworked as though they were insanity assessments. And when the criminal inquiry reaches the substantive law, currency is everything: the insanity provision candidates first learned in the Indian Penal Code has been recodified into the Bharatiya Nyaya Sanhita, and the older provision is historical wording for an act committed after the recodification took effect. It is not automatically superseded for an act committed before

that date, because the recodifying statute's own transition clause keeps the older provision live as the operative law for offences from before commencement. The synthesis does not restate either provision - it is owned by this chapter's topic on criminal responsibility - but it insists that the offence date, not the date of writing, is what decides which version is named.

GOOD TO REMEMBER

When a patient is about to cross from one of these questions to the next, write the opinion to the decision and the moment actually in issue, and resist the pull to answer the broader question you can see coming. A capacity opinion for consent to admission is not a fitness opinion and not a testamentary opinion; date it, name its decision, and let the next question be assessed on its own facts when it arrives.

43.6 One judgement, three readers

The seam runs through risk as well as through capacity. A single clinical judgement that a patient carries some degree of **violence risk** does not hold one fixed meaning; it is read differently by each forum that receives it, because each brings a different question and does a different thing with the answer. The risk factors and the structured and actuarial instruments that generate the judgement are taught in this chapter's risk-assessment topics; what the synthesis adds is that the same judgement is not the same fact to a court, to a Review Board and to a ward.

WHO READS THE RISK JUDGEMENT	THE QUESTION THEY BRING TO IT	WHAT THEY DO WITH IT
The criminal or civil court	Is this person a risk the law must act on	Disposal, detention or conditions on liberty
The Mental Health Review Board	For a supported admission, should the admission or readmission be permitted, or should discharge be ordered; for a restraint episode, has the establishment persistently and wilfully ignored the restraint limits	Permit the admission or readmission, or order discharge, on the specific admission-review route; or, for restraint, issue the separate desist order the Act provides. There is no free-standing power to vary a detention or restriction outside these named routes
The ward team	How are this patient and others to be kept safe now	The clinical management plan, bounded by the statutory limits on restraint and seclusion

The practical corollary is that a risk opinion must be written for the reader who asked for it. A formulation built to guide a ward's management plan is answering "what do we do now", and it is not, without more, an answer to the court's question of whether detention is justified or to the Board's question of whether a restriction remains proportionate. The judgement can be the same and its use quite different.

IN INDIA

Every capacity and risk question in this chapter is answered under an Indian statute and before an Indian forum, and the examiner marks the Indian provision, not the Western test it descends from. Treatment-decision capacity and the review of detention sit with the Mental Healthcare Act and its Review Board; guardianship with the disability legislation and its committee route or the general civil machinery; criminal responsibility and fitness with the recodified criminal law before the trial court. A technically correct English or American answer to an Indian question still loses the mark here, because the question is written to test the Indian route, not the ancestor it grew from.

PITFALL

The recurring real-world error is to let a single opinion travel beyond the question it was written for. A capacity assessment recorded once, undated and unqualified, is read months later as though it still held and covered a different decision; a risk note written for the ward is quoted to a court as if it settled the court's question; a superseded section is copied forward as current law. Each is the same mistake - an opinion detached from the decision, the moment and the forum that gave it meaning - and each reaches a real report, not merely an exam script.

43.7 The map to carry into the hall

The map, when memory fails. If the chapter blanks you under pressure, the fastest way back in is not to grope for a section number but to place the question on the map. Ask which of the two spines it belongs to, and then find the capacity beneath it. Almost every question this paper can set is a statute you practise inside, a question a court asks, or a judgement of capacity underneath both, and naming which one narrows the search until the owned detail surfaces. Even when the exact section will not come, the map gives you a structured stem to write around instead of an empty page.

MNEMONIC

Law inside, court across, capacity beneath

Rebuild the whole chapter from three phrases. **Law inside** is the legislation you practise within - the Mental Healthcare Act, the Rights of Persons with Disabilities Act and the narcotics law. **Court across** is the run of questions a court puts to you - responsibility for an act, competence to will, contract or marry, fitness to stand trial, and risk to others. **Capacity beneath** is the one foundation carrying both, because each of those is finally a question about whether a particular person, for a particular decision, at a particular time, could do what the law asked. Recall the two spines, then the foundation under them, and the chapter reassembles itself from memory.

That is the whole of the synthesis. The tests differ in their words and their forums, but they rhyme, because each is asking one question in a slightly different accent. Hold the question and the accents sort themselves.

Capacity is one construct seen from many benches - always ask which decision, at which moment, before which forum, and the chapter's dozen tests collapse into one question with a dozen answers.

Apply and consolidate

44 · Applying the chapter

Why this closer works you, not the page. You have met every statute and every test in this chapter on its own terms. A worked vignette does the one thing the separate topics cannot: it hands you a presentation with no label on it and asks you to find the legal question inside it, fix the moment at which that question must be answered, and give an answer you could defend to a court. That is precisely what the long case and the viva examine, and it is where otherwise prepared candidates still come undone, because reciting a provision and deploying it against messy facts are different skills that fail independently. Every vignette below runs the same four beats - a short presentation, the decision point it forces, the reasoning a candidate must show, and the answer - and between them they span the four kinds of question the paper builds its scenarios from. The sections, durations, cases and instruments the reasoning deploys are taught, and cited to their source, in the topics that own them; what these pages rehearse is the judgement that puts them to work.

Beneath all four questions sits a single construct, **capacity** - whether a particular person, faced with a particular decision, at a particular time, could do the thing the law asked of them. The four families the paper draws its vignettes from are best held as one set, so that each scenario arrives as a member of a family you already recognise:

- a decision under the mental health legislation about how a person who may be unable to consent is to be admitted and treated;
- a civil assessment of whether a person is competent to a specific act, such as making a will or entering a contract;
- a criminal question of whether unsoundness of mind excuses an act, or unfits a person for trial;
- and a formulation of the risk that a patient will be violent, with the management plan that must follow it.

Read each vignette for the capacity beneath its surface and the answer begins to organise itself.

44.1 How to work a forensic vignette

Before the cases, a word on method, because the order in which you attack a vignette decides whether you answer the question asked or a neighbouring one. The first move is always to identify which of the four questions you are being given, because both the material you deploy and the moment you fix follow from that identification and from nothing else. The second move is to fix the time at which the question must be answered - the time of the act, the time of the

will, the time of the trial, the present moment on the ward - because the same person can hold a capacity at one instant and lack it at another. The third is to apply the specific standard for that decision, not a global impression of the person. The fourth is to answer in the register the forum expects: a ward decision is defended by the statute and the least-restrictive principle, a court opinion by the evidence and the correct current citation.

RULE **Name the question, then fix the moment, before you reach for a section.** A vignette punishes the candidate who recites a provision before deciding which question is being asked. Identify the family the scenario belongs to, anchor the assessment to the exact moment the law cares about, and only then retrieve the standard and its citation. Do it in the other order and you will produce an accurate answer to a question you were not asked, which earns nothing.

Present	Decide	Reason	Answer
READ THE SCENARIO	NAME THE LEGAL QUESTION	FIX THE MOMENT, APPLY THE STANDARD	IN THE FORUM'S REGISTER

44.2 Vignette: an admission that will not be consented to

Presentation. A family brings a man in mid-life to the emergency room. For some weeks he has barely slept, has stopped eating, and believes his neighbours are poisoning the household water; today he has threatened to leave and confront them. He does not accept that he is unwell, and he refuses to remain.

Decision point. On what lawful basis, if any, may he be admitted and treated when he will not consent, and what stops that basis from becoming simple detention at the family's request.

Reasoning to show. First place the question: this is an admission decision under the mental health legislation, not a forensic one, and its pivot is the capacity to make the treatment decision, assessed for this decision at this time and not read off his diagnosis. If, on assessment, he retains that capacity, he cannot be held against his will merely because he is unwell or because relatives wish it; the statute's default and its stated preference is the independent route, but that route runs only on the person's own free request, so a capacitous person who refuses admission cannot be admitted as an independent patient at all. If instead his mental state means he cannot understand the relevant information, appreciate the reasonably foreseeable consequences, or communicate the treatment decision, the **supported admission** route opens - but only where the statutory criteria are also met, namely mental illness of a severity that requires inpatient care together with a likelihood of harm or of an inability to meet basic self-care, and it proceeds through his **nominated representative** rather than on the ward's say-so. Even then the admission is not a blank cheque: it is time-bound, it runs under the statutory review timetable, it is open to scrutiny by the review board, and it must be the least restrictive option that meets the need. What is said to the family throughout is the plan and its purpose in plain terms; the condition itself is not labelled to them.

Answer. He is not detainable simply for being ill. Assess his capacity for the treatment decision now; if it is present, he can be admitted only as an independent patient on his own free request, so a capacitous man who refuses is not admitted at all; if it is absent and the severity-and-risk

criteria are satisfied, admit by the supported route through the nominated representative, least-restrictively and under board oversight, and keep the independent route in view for the moment his capacity returns.

IN INDIA

The Indian mental health legislation replaced a custodial reception model with a rights-and-capacity one, and the machinery in this vignette is the visible proof of that shift. The nominated representative and the review board are the Indian statute's safeguards against exactly the family-driven, open-ended detention the old law permitted, and supported admission is its carefully bounded substitute for the reception order, a route the nominated representative applies for when a person has high support needs and the severity-and-risk threshold is crossed. Answer the Indian route, not a generic Western involuntary-admission framework, because that route and its safeguards are what the paper is testing.

44.3 Vignette: is she fit to change her will

Presentation. An elderly widow, cared for by one of her several adult children, asks whether she is fit to change her will in a way that would favour that child. She has a fluctuating cognitive disorder with clearly better and worse periods within hours of each other.

Decision point. Does she have the capacity to make this will, and at what moment is that capacity to be judged.

Reasoning to show. Place the question: this is a civil capacity assessment, and capacity here is both decision-specific and time-specific. **Testamentary capacity** is not global competence and it is not the capacity to consent to treatment; it is the specific capacity to make a valid will, resting on a sound disposing mind - broadly, that she grasps the nature and effect of making a will, has a workable sense of the property she is disposing of and of those with a claim on her provision, and that no disorder of mind is perverting that judgement. The full limbs and the standard are set out where this chapter teaches testamentary capacity; a vignette applies them to the facts rather than reciting them. Because the capacity the law fixes on is ordinarily judged at execution, her fluctuating disorder settles nothing by itself: she may make a perfectly valid will in a lucid interval at execution, and a recognised exception also validates a will where full capacity was present when she gave the instructions, the will faithfully embodies them, and at execution she still understands enough to know she is executing that instructed will, even without the full disposing mind at that hour. The presence of a diagnosis does not decide it, and the presence of the specific understanding at the specific moment does. Note too the assessor's independence, because an opinion is worth less if the assessor is the instrument of the interested child.

Answer. Assess the specific limbs at execution, the moment the law ordinarily fixes on, not her global state or her worst hour, and hold the recognised exception in reserve for a will faithfully drawn from instructions given in an earlier, fully capacitated interval. A fluctuating disorder is entirely compatible with a valid will made in a lucid interval, so the task is to establish and document the disposing mind at that moment. Whether she carries a diagnosis is not the question; whether she holds the capacity for this decision, now, is.

44.4 Vignette: responsible then, fit now, or neither

Presentation. A man is charged with a serious assault on a stranger. At the time of the act he was acutely psychotic and believed the stranger was about to kill him. Some months later, awaiting trial and only partially treated, he remains disorganised, cannot follow the charges, and cannot give his lawyer coherent instructions. The court asks for a psychiatric opinion.

Decision point. This is two questions wearing one presentation - was he criminally responsible at the time of the act, and is he fit to stand trial now - and the commonest failure is to answer one with the other.

Reasoning to show. Criminal **responsibility** is judged at the time of the alleged act: the question is whether unsoundness of mind then deprived him of the capacity the substantive provision requires, broadly the capacity to know the nature of what he was doing or that it was wrong or contrary to law. Which provision governs turns on the date of the alleged act: the recodified penal code applies to an act on or after the recodification's commencement, while the superseded penal-code section remains the live law, not mere historical origin, for an act before that date, because the recodifying statute's own savings clause keeps it in force for those earlier acts. The burden of proving the exception rests on the defence, under the recodified law of evidence for a proceeding not already pending when that law commenced, and under the historical evidence provision, likewise kept live by its own savings clause, for a proceeding that already was pending; the wording in both eras descends from the same historical common-law rules. **Fitness to stand trial** is a wholly separate capacity, judged at a different moment - the time of the trial - and it asks only whether he can now understand the proceedings and the charges, appreciate their consequences, and instruct his defence; it says nothing about his mind at the time of the act. The two run on separate clocks: a man may have been responsible, being well when he acted, yet be unfit now; or be presently unfit but, once treated, become triable for an act whose excusability is still an open question. Whatever is communicated to him and his family is done without labelling the condition to them.

Answer. Separate the questions and anchor each to its own moment. On responsibility, opine on his mental state at the time of the act against the substantive standard that applied on that date, state the alleged-act date because it selects the recodified provision or the superseded provision that its own savings clause keeps live for an earlier act, and place the burden on the defence under whichever evidence provision the proceeding's pendency at commencement in turn selects. On fitness, assess his present ability to understand and participate; as presented he is unfit now, so the live issue is restorability on a timetable the court sets. The trial waits for fitness; it does not answer, or replace, the responsibility inquiry.

TRAP **Answering the responsibility question with the fitness answer, or the reverse.** Because both turn on mental state and both arise in the same case, candidates collapse them into one opinion - concluding that a man too unwell to stand trial must therefore have been insane at the time, or that a man now recovered must have been responsible. They are two capacities at two moments on two clocks. Fix the time first, and the two questions come apart cleanly; skip that step and you will confidently answer the one the court did not ask.

PITFALL

The recurring real-world error on this material is one of currency: writing an opinion or a court report that cites the superseded penal-code insanity section, or the old evidence-law burden provision, as though it were still the live law after the substantive criminal statutes were recodified. The doctrine usually survives the slip almost unchanged, so the reasoning still reads soundly - but the citation does not survive, and an opposing advocate who spots a report resting on a repealed section can weaken the witness before a word of substance is heard. Confirm the provision is the one in force, then cite it.

44.5 Vignette: the threat on the ward

Presentation. An inpatient recovering from a psychotic relapse has begun making specific threats against a named member of staff. He has one documented serious assault during a previous untreated episode, uses a substance intermittently while on leave, and is poorly adherent to medication. The team is asked for a risk formulation and a plan.

Decision point. How to formulate the risk and what to do about it, without either over-detaining him or under-protecting the person he has threatened.

Reasoning to show. Place the question: this is a **violence risk** formulation, not a verdict that the man is dangerous as a fixed trait. The modern task is to separate the factors that cannot move from the factors that can. His past assault and his historical pattern are static: they raise the baseline and must be weighed, but no intervention changes them. The current threats, the untreated psychotic symptoms, the substance use and the non-adherence are **dynamic risk factors**, and they are the entire point of the exercise, because they are where management acts. The estimate itself is best organised by a structured professional judgment approach, which weighs history, present clinical state and future context together, rather than by an actuarial score read in isolation or by unaided clinical intuition; the specific instruments are taught where this chapter owns them and are applied here as the frame. Management then targets the dynamic column - treat the psychosis, address the substance use, restore adherence, adjust leave, and contain the immediate situation - and any physical restraint used in an acute moment is bounded by the statute's limits on that measure, not left to clinical discretion alone, while seclusion and solitary confinement are prohibited outright and have no such bound to work within. The threat against a named person also raises a duty to weigh that person's safety alongside the patient's rights.

Answer. Formulate by separating static from dynamic factors; estimate by structured professional judgment rather than a bare score or a hunch; and build a plan that moves the dynamic factors - treatment, substance-use management, adherence, graded leave - while keeping any acute restraint within the statutory ceiling. Document the reasoning, because a risk opinion is judged on the quality of its method, not the confidence of its conclusion, and reassessment is part of the plan because dynamic risk, by definition, changes.

GOOD TO REMEMBER

A risk formulation that lists factors but never says which of them can be moved is a description, not a plan. On the ward the whole value sits in the dynamic column, because that is the only column you can act on, and a plan is simply the set of interventions aimed at those movable factors plus the date you will look again. If your risk note reads the same after treatment as before it, you have written a character sketch, not a management plan.

44.6 Vignette: the certificate that changes audience

Presentation. An employer asks you to certify whether a patient, recovered from an illness that had kept him off work, is now fit to resume his duties. Midway through, the request expands: the same patient is now a complainant in a criminal matter, and his lawyer asks you for a report the court can rely on.

Decision point. Are these the same task, and are they both yours to perform.

Reasoning to show. They are two different certifications, with two different audiences and two different duties, and the examiner sets exactly this drift to see whether you notice the boundary. The fitness-to-resume-work certificate is an occupational-fitness judgement made for the employer, asking whether the person can safely and effectively perform the role, and it belongs to this chapter's civil-certification material. The report and certificate written for a court are a different instrument altogether, governed by the expert's duty to the court and by its own frame of consent, confidentiality and the form of expert evidence - and that material is owned by the Forensic ethics, consent and legal procedure notes, named here and deliberately not taught. The same discipline governs the other borders a forensic scenario can wander into: were the matter to turn on a child, whether custody or a juvenile in conflict with the law, the governing statutes belong to the Child psychiatry: assessment, treatment, services and protection notes, and the clinical management of any substance use belongs to the Substance use disorders notes. Knowing where your own certificate stops is itself an examined skill.

Answer. Sign the occupational-fitness certificate on its own criteria as this chapter's task, and do not let it slide into a court report, which is a distinct duty owed to a distinct audience and is the business of the Forensic ethics, consent and legal procedure notes. Where a scenario reaches into child law or the clinical side of substance use, name the boundary and cross-refer rather than answering with a neighbour's material.

44.7 The four domains on one grid, the thread, and the map

Set side by side, the vignettes make the chapter's architecture visible in a single view. Each turns on a different family of question, yet each resolves to the same underlying move - name the decision, fix the moment, apply the standard for that decision - so the grid below is less a summary than a demonstration that one habit answers all four.

VIGNETTE	DOMAIN IT EXERCISES	THE DECISION POINT	THE CAPACITY OR QUESTION BENEATH
The unconsented admission	Admission under the mental health legislation	On what lawful basis may an unwilling person be admitted and treated	Capacity to make the treatment decision, now
The changed will	Civil capacity assessment	Is she competent to make this will, and when is that judged	Testamentary capacity, at the moment of the act
Responsible then, fit now	Criminal responsibility and fitness to plead	Was he excused at the act, and can he be tried now	Two capacities at two moments on two clocks
The threat on the ward	Violence risk formulation and management	How to formulate the risk and act on it proportionately	Static versus dynamic factors, and where management can move
The certificate that changes audience	Boundary and scope discipline	Whose task is this, and where does my certificate stop	The duty owed and the audience addressed

The thread, one last time. Every vignette in this closer is, underneath, a capacity question, and capacity has two properties worth committing to memory above any single test. It is **decision-specific**, so a person may hold it for one decision and lack it for another at the very same moment, and one capacity never settles another. And it is time-specific, so it is anchored to a fixed instant and can be present today and absent a month ago, or the reverse. The forensic and civil standards differ in their words, but each is asking whether this person, for this decision, at this moment, could do what the law required of them; and once you see that, the messy presentation in front of you stops being a puzzle and becomes a place on a map you already hold.

MNEMONIC

Law inside, court across, capacity beneath

Rebuild the chapter from three phrases when a vignette empties your head. **Law inside** is the legislation you practise within - the Mental Healthcare Act, the Rights of Persons with Disabilities Act and the narcotics law. **Court across** is the run of questions a court reaches in to ask - was the accused responsible, is a person competent to will, contract, marry or stand trial, and is a patient a risk to others. **Capacity beneath** is the single foundation carrying both, because each is finally a question about whether a particular person, for a particular decision, at a particular time, could do what the law demanded. Place the scenario on the two spines, find the capacity under it, and the answer you could not summon cold usually surfaces on its own.

Every vignette in this chapter is a capacity question - name the decision, name the moment, and name the forum, and the answer is most of the way found.

45 · Consolidation

Why this closer exists. You have read the chapter; the marks come from being able to produce it with the book shut. Everything below is built for **active recall**, so every line is a question and not one of them prints its answer alongside - the instant your eye lands on the answer, the effortful retrieval that actually fixes a fact in memory is spent for nothing. Read each prompt, answer it aloud or on paper from memory, and only then turn back to the relevant teaching section to mark what you produced. If a prompt asks for a section number, a threshold, a case or an instrument, say the number, the case or the name; the whole point is that these pages withhold it.

One idea runs the length of this chapter and is worth holding as you revise: **capacity**. Whether the question is a treatment refusal, a will, a contract, a criminal charge or a fitness-to-plead inquiry, the law is finally asking whether a particular person could make a particular decision at a particular time. Keep that thread in view and the statutes stop looking like unrelated laws and become one subject seen from several benches. The prompts are grouped into the six areas the paper draws from, and a short set of discriminations and a master map close the chapter.

45.1 Working the prompts

Before the content, a word on method, because how you use a prompt list decides whether it does anything. Retrieval is not a test you sit at the end of revision; it is the revision. The act of hauling an answer out of an empty head is what lays down the memory, and it feels harder and less productive than rereading precisely because it is doing the work rereading does not.

RULE **Retrieve first, read second.** Treat every prompt as a closed-book question, commit to the fullest answer you can generate cold, and open the notes only to correct what you generated. Rereading a section you have already read builds fluency with the page, not access to the fact; the effortful, slightly uncomfortable pull of recall is the only part of the loop that actually consolidates. The discomfort is the signal that it is working.

Read	Retrieve	Check
THE PROMPT ONLY	THE ANSWER FROM MEMORY	AGAINST THE SECTION

TRAP **Mistaking recognition for recall.** A model answer read the night before feels obvious on the page, and that fluency is quietly misread as knowledge; in the hall, asked to produce the same answer from nothing, the candidate stalls. Recognising an answer when you see it and generating it when you cannot are different skills, and only the second earns marks. If a prompt feels too easy to bother answering, that is the illusion talking - answer it anyway, out loud, and find out.

IN INDIA

This chapter is Indian statute end to end, and the examiner marks the Indian provision, not the Western test it descends from. When a prompt asks for a rule, retrieve the Indian Act, the Indian certifying instrument and the Indian case law by name and, where you can, the section. A technically correct English or American answer to an Indian question still loses the mark, and the questions are written to catch exactly that substitution.

45.2 The Mental Healthcare Act

The largest statute in the chapter and the one that most rewards precise recall of definition, section and procedure. Answer each strand from memory in a sentence or two before you check.

1. State the definition of mental illness the Act adopts and the test by which a person is judged able to make a mental-healthcare decision; then walk the advance directive - who may make one, how it is revoked, and on what grounds it can be overridden - and say who the nominated representative is, how that person is appointed, and what duties the role carries.
2. Distinguish independent from supported admission with the discharge route and safeguards for each; recall the composition and functions of the review board and how it differs from the central and state authorities; and name the ways this Act breaks from the mental health law that preceded it, with the shift in philosophy behind the change.
3. Which provision decriminalizes attempted suicide, what presumption does it raise and on what conditions does that presumption rest; separate the prohibited from the restricted procedures and give the consent position for modified treatment that induces a seizure, including where the patient is a minor; and recall the statutory ceiling on restraint and seclusion together with the offences the Act creates.

45.3 The Rights of Persons with Disabilities Act and the National Trust

A rights-based statute with a benefits-and-certification machinery attached. The trap in this area is borrowing one certificate's instrument for another purpose, so keep the aim of each in view.

1. Recall the salient features of the rights-based disability statute and where mental illness sits among the disabilities it recognizes; then name the instrument and the authority used to certify disability due to mental illness and the threshold at which it becomes a benchmark disability.
2. State the benefits, reservations and guardianship that follow, and how limited guardianship departs from the older plenary model; then recall the National Trust route to guardianship and the local committee that grants it.

45.4 The narcotics law

Here the recall is of the law only; the de-addiction pharmacology behind these provisions belongs to the Substance use disorders notes and is not what the forensic paper is asking for.

1. Recall how the statute classifies controlled substances and the logic that scales its penalties from lesser to graver quantities.
2. State the treatment and de-addiction provisions and the immunity available to an addict who volunteers for treatment - and, crucially, the conditions on which that immunity depends, since an immunity quoted without its conditions is worth little.

45.5 Criminal responsibility and forensic assessment

The busiest forensic band and the one where currency of the law matters most, because the substantive criminal statutes were recently recodified. Retrieve the transition rule before the

provision: fix the offence date and the proceeding's pendency at the recodification's commencement, then select the saved or the new provision accordingly.

1. Recall the common-law rules that supply India's insanity standard and the limbs a defence must establish; then name the current substantive provision and the code that now houses it, the burden of proof and who bears it, and the older sections these replaced; and contrast the alternative tests of responsibility with the retained standard, saying why India keeps the narrower frame.
2. Distinguish fitness to stand trial from criminal responsibility by the moment at which each is judged, and recall the criteria and assessment of fitness; then define diminished responsibility and automatism and where each operates; and separate mens rea from actus reus with the legal senses of intent.
3. Recall the deception-detection techniques, the case that governs their admissibility, and the constitutional protection and the consent it demands; then recall the indicators of malingering and the approach to a suspected feigned illness; and recall the psychiatric issues that recur in homicide and filicide.

PITFALL

The commonest real-world error on this material is one of **transition logic**: citing the new penal-code provision for an offence that predates the recodification, or the new evidence-code burden provision for a proceeding already pending when the recodification commenced, without first checking what the repeal-and-savings clauses preserve. Confirm the offence date and the proceeding's pendency at commencement before you commit either to a report or to an exam script; an old citation is not wrong merely for being old, and a candidate who forgets the savings clauses and calls it wrong on age alone is the one making the error.

45.6 Civil and family capacity

Several distinct capacities and several distinct certificates crowd this band, and the marks go to keeping them apart. Each is capacity for a specific decision, judged at a specific time.

1. Recall the limbs of testamentary capacity and the standard of a sound disposing mind; then state when a contract is void for want of competence due to unsoundness of mind, distinguish this from a voidable contract arising out of defective free consent, and give the moment at which soundness is judged; and distinguish a marriage that is void or voidable for mental illness from a valid marriage dissolved by divorce on that ground, with the different statutes and the different thresholds each needs.
2. Recall how a psychiatric evaluation informs a child-custody decision, and the routes for guardianship and for management of the property and affairs of a mentally ill person; then separate the certifications that are easily conflated - disability certification, fitness to resume work, and compensation or pension - by purpose and instrument; and recall the psychiatric fitness assessment of prospective adoptive parents.

45.7 Violence risk and dangerousness

Modern forensic practice has largely replaced the older language of **dangerousness** with the language of violence risk, and the prompts track that shift, because a candidate who answers with the trait model rather than the risk model loses the mark the question is testing.

1. Explain how and why the field moved from labelling a person dangerous to assessing violence risk; then recall the principal structured professional judgment instrument and the way it groups its items, and the actuarial tools and the psychopathy checklist beside it, with the trade-off between actuarial prediction and structured clinical judgment.
2. Separate static from dynamic risk factors and recall the factors specific to mental illness; then recall the acute and the longer-term management of the violent and high-risk patient, and the statutory limits that bound any restraint decision you take.

45.8 The discriminations, the thread and the map

A small number of pairings account for most of the avoidable errors on this chapter. For each, the retrieval to rehearse is the distinction itself, not either definition, because the examiner sets these pairs precisely to see whether you can hold them apart under pressure.

DO NOT MERGE	THE DISTINCTION TO RETRIEVE
Prohibited and restricted procedures	Which category bars a procedure outright and which only gates it behind consent or permission, and what falls in each
Marriage nullity and divorce	Which route treats a marriage as never validly formed and which dissolves one that was valid, and the grounds each demands
Criminal responsibility and fitness to plead	Which is judged at the time of the act and which at the time of the trial
Disability, fitness-to-work and compensation certificates	Distinct purposes and distinct instruments; name the aim of each and never lend one certificate's instrument to another
Static and dynamic risk factors	Which shift with treatment and which do not, and why management targets the one it can move
Actuarial and structured clinical judgment	Which yields a probability by rule and which yields a formulation by guided judgment, and the trade-off between them

The thread, one last time. Every prompt in this closer is, underneath, a capacity question, and capacity has two properties worth committing to memory above all else. It is **decision-specific**: a person may have the capacity to make a will and not to run a business, so the answer for one decision never settles another. And it is **time-specific**: capacity can be present today and absent a month ago, or the reverse, so an opinion is anchored to a moment and not to the person for all time. The forensic and civil tests differ in their words, but each is asking whether this person, for this decision, at this moment, could do what the law requires of them.

MNEMONIC

Law inside, court across, capacity beneath

Rebuild the chapter from three phrases. **Law inside** is the legislation you practise within - the Mental Healthcare Act, the Rights of Persons with Disabilities Act and the narcotics law. **Court across** is the run of questions a court puts to you - was the accused responsible, is a person competent to will, contract, marry or stand trial, and is a patient a risk to others. **Capacity beneath** is the single foundation carrying both, because each of those is finally a question about whether a particular person, for a particular decision, at a particular time, could do what the law demanded. Recall the two spines, then the foundation under them, and the chapter reassembles from memory.

GOOD TO REMEMBER

If a legislation-or-forensic question blanks you in the hall, run the map before you panic. Ask which of the three it is: a statute I practise inside, a question a court asks, or a judgment of capacity. Placing the question on the map narrows the search and usually surfaces the section, the test or the instrument you could not summon cold, and even when it does not, it gives you a structured stem to write around rather than an empty page.

Every question in this chapter is a capacity question - name the decision, name the moment, and name the statute, and the answer is most of the way found.

Previously asked

There is no indexed past-question bank for this chapter, so nothing in the table below is a catalogued past question and no board or year is claimed for any of them. Attributing a paper the index does not hold would be a fabrication, so in place of a board of origin each row is marked Representative, and the questions are written in the register an examiner uses. Legislation and forensic psychiatry are examined heavily and in every form the paper allows, as long answers, as short notes and in the viva, so the list maps the examined spine of this chapter rather than one board's recent record. Read it as a high-yield revision map, not as a set of questions on record.

QUESTION	MARKS	ASKED
Enumerate the rights of a person with mental illness under the Mental Healthcare Act 2017, and discuss the capacity to make treatment decisions and the advance directive, including how an advance directive may be reviewed or overridden.	10	Representative
Describe the provisions for admission of a person with mental illness under the Mental Healthcare Act 2017, contrasting independent admission, supported admission up to thirty days, and supported admission beyond it.	10	Representative
Prohibited and restricted procedures under the Mental Healthcare Act 2017.	*5*	Representative
Decriminalisation of attempted suicide under the Mental Healthcare Act 2017 (section 115).	*5*	Representative
Composition and functions of the Mental Health Review Board.	*5*	Representative
Describe the salient features of the Rights of Persons with Disabilities Act 2016 as they apply to mental illness, and outline the procedure for certification of psychiatric disability.	10	Representative
IDEAS (Indian Disability Evaluation and Assessment Scale).	*5*	Representative
Immunity from prosecution for an addict who volunteers for treatment under the NDPS Act 1985 (section 64A).	*5*	Representative

QUESTION	MARKS	ASKED
Discuss criminal responsibility in mental illness. Explain the McNaughton rules and the insanity defence under the current Indian law (Bharatiya Nyaya Sanhita section 22), and outline the assessment of fitness to stand trial.	10	Representative
Testamentary capacity and the assessment of a sound and disposing mind.	*5*	Representative
Mental illness as a ground for annulment of a Hindu marriage, and the distinction between a void and a voidable marriage.	*5*	Representative
Structured professional judgement in violence risk assessment.	*5*	Representative

The shape of these questions is worth reading before their content. A ten-mark question that opens with enumerate or describe wants a structured map rather than a definition, and the marks are won on the discriminations this chapter turns on: the disjunctive three-limb capacity test, the boundary between supported admission up to thirty days and supported admission beyond it, the split between a prohibited procedure and a merely restricted one, and the difference between a marriage that is void and one that is voidable. A short note carries fewer marks but the same demand for the exact section and the exact modal verb, because shall and may are not interchangeable and a note that gives the wrong section number reads as a note that has not opened the Act. Legislation is the one part of this paper whose answer is checkable against a single primary text, which is precisely why the examiner rewards the candidate who cites the section and marks down the one who paraphrases it.

TRAP **An unasked topic is not a low-yield topic, and a dated citation is a wrong one.** The absence of a catalogued bank for this chapter is a fact about the index, not about what the examiner may set, and legislation is tested every year in one form or another. Two currency traps decide the criminal-responsibility answer. The substantive insanity exception is now Bharatiya Nyaya Sanhita section 22 and the burden of proof rests on Bharatiya Sakshya Adhiniyam section 108, both in force from 1 July 2024; the Indian Penal Code section 84 that older textbooks name carries word for word the same cognitive test but is the historical provision, and citing it as the current law dates the answer. Inside the Mental Healthcare Act the advance-directive override is section 11, not section 13, which is the professional-liability provision; and the Act's definition of mental illness is a different provision from the Schedule definition in the Rights of Persons with Disabilities Act 2016. Prepare the sections and the discriminations, not the past paper.

The quick review

One table, read down the left column and cover the right. Every line is taught in full somewhere above and nothing here is new: each is that provision's single must-hold line, the section number and its operative rule lifted from the passage that teaches it, so a line you cannot recover is a section to reread rather than a fact to memorise here. Modal verbs are load-bearing: where the statute says shall it is kept as shall and where it says may it is kept as may, because that difference often decides the answer. Current criminal law is stated as current, the Bharatiya Nyaya Sanhita and the Bharatiya Sakshya Adhiniyam in force for offences on or after 1 July 2024; the older Indian Penal Code position is kept only where a candidate must still recognise it as the historical provision.

ASK	HOLD
MENTAL HEALTHCARE ACT 2017: DEFINITIONS AND CAPACITY	
DEFINITION OF MENTAL ILLNESS (S.2(1)(S))	A substantial disorder of thinking, mood, perception, orientation or memory that grossly impairs judgment, behaviour, reality-testing or the ordinary demands of life; it INCLUDES conditions of alcohol and drug use and EXPRESSLY EXCLUDES mental retardation.
DETERMINATION OF MENTAL ILLNESS (S.3)	Determined by nationally or internationally accepted standards including the latest ICD, never by political, economic or social status or moral non-conformity; and s.3(5), a determination of mental illness is not the same as unsound mind unless a competent court so declares.
CAPACITY, THE THREE-LIMB TEST (S.4)	Every person is DEEMED to have capacity if able to understand the relevant information, OR appreciate the reasonably foreseeable consequences, OR communicate the decision; the limbs are disjunctive in the bare text, and a choice others think wrong does not by itself negate capacity.
ADVANCE DIRECTIVE AND NOMINATED REPRESENTATIVE	
ADVANCE DIRECTIVE, THE RIGHT (S.5)	Any person who is not a minor may make a written directive stating how they wish, and wish not, to be treated and who is to be nominated representative; it takes effect only once capacity is lost, and a later capacitous decision over-rides it (s.5(4)).
HOW AN ADVANCE DIRECTIVE IS OVERRIDDEN	Three separate routes, do not conflate: the maker's own later capacitous decision (s.5(4)); the maker's revocation or amendment at any time (s.8); and the Board machinery (s.11), where a mental health professional, relative or care-giver applies and the Board, after hearing all parties, may uphold, modify, alter or cancel it. The override is s.11, not s.13; s.13 is professional liability.

ASK	HOLD
NOMINATED REPRESENTATIVE, DEFAULT ORDER (S.14, S.17)	Where none is appointed the order is the directive-named individual, then relative, then care-giver, then a suitable person appointed by the Board, then the Director of Social Welfare; the duty (s.17) is supported decision-making, not substituted judgment.
RIGHTS, ADMISSION AND REVIEW BOARDS	
CORE RIGHTS (S.18 TO S.23)	Access to mental healthcare (s.18), community living (s.19), protection from cruel or degrading treatment with no compulsory tonsuring or forced labour (s.20), equality with physical illness including insurance parity, every insurer shall cover mental illness on the same basis (s.21(4)), information (s.22) and confidentiality with enumerated exceptions (s.23).
INDEPENDENT ADMISSION (S.85, S.86, S.88)	Admission should be independent wherever possible (s.85); a non-minor may request admission and self-discharge, treated only with informed consent (s.86); but an MHP may hold an independent patient up to twenty-four hours to assess for supported admission (s.88(3)).
SUPPORTED ADMISSION UP TO THIRTY DAYS (S.89)	On the nominated representative's application, examination by one psychiatrist plus one MHP or medical practitioner; LIMITED to thirty days; report to the Board within three days for a woman or minor and seven days for others; Board review only on application, not automatic pre-authorisation.
SUPPORTED ADMISSION BEYOND THIRTY DAYS (S.90)	Two psychiatrists examine independently, harm shown consistently over time (stricter than s.89 recently); Board review is MANDATORY, the Board within twenty-one days permits the admission or orders discharge; up to ninety days first, then 120, then 180 days each time.
MENTAL HEALTH REVIEW BOARD (S.73, S.74, S.82)	Constituted by the State Authority (s.73); chaired by a District Judge with a Collector's representative, one psychiatrist and one medical practitioner, and two members who are persons with mental illness, caregivers or NGO representatives (s.74); it registers or cancels directives, appoints representatives, decides admission appeals, and may impose a penalty up to five lakh rupees (s.82).
AUTHORITIES AND REGISTRATION (S.33, S.43, S.45, S.55)	The Central Mental Health Authority (s.33) registers Central-Government establishments (s.43); every State sets up a State Authority (s.45) which registers all other establishments in the State (s.55); each within nine months of assent.
TREATMENTS, RESTRAINT AND ATTEMPTED SUICIDE	
EMERGENCY TREATMENT (S.94)	Any registered medical practitioner may treat to prevent death, serious self-harm, harm to others or serious property damage, subject to the representative's informed consent where available; it shall not use electro-convulsive therapy; limited to seventy-two hours, extendable to seven days in a declared disaster.

ASK	HOLD
PROHIBITED PROCEDURES (S.95)	Absolutely barred: unmodified ECT (without muscle relaxants and anaesthesia, no exception), ECT for minors, sterilisation as a treatment for mental illness, and chaining in any form; the narrow gate (s.95(2)) allows ECT for a minor only with the guardian's informed consent AND prior Board permission.
RESTRICTED PROCEDURE, PSYCHOSURGERY (S.96)	Psychosurgery is not banned but restricted, permitted only on BOTH the patient's informed consent AND the Board's approval; contrast s.95, an outright ban with the single minor-ECT exception.
RESTRAINT AND SECLUSION (S.97)	Seclusion and solitary confinement are absolutely prohibited; physical restraint only when it is the sole means to prevent imminent harm and is authorised by the psychiatrist in charge, kept time-limited, never as punishment or for staff shortage, the representative informed within twenty-four hours and every instance reported monthly to the Board.
ATTEMPTED SUICIDE (S.115)	Two limbs. Notwithstanding section 309 of the Penal Code, a person who attempts suicide is PRESUMED, unless proved otherwise, to have severe stress and shall not be tried or punished (a rebuttable presumption, not a repeal); and the appropriate Government has a DUTY to provide care, treatment and rehabilitation to reduce recurrence.
GENERAL PENALTY (S.108)	First contravention up to six months or up to ten thousand rupees or both; a subsequent contravention up to two years or a fine of fifty thousand to five lakh rupees or both.
THE SHIFT FROM THE 1987 ACT	The Act repealed the Mental Health Act 1987, moving from a custodial licensing-and-guardianship model to a rights-based, capacity-based framework aligned with the UNCRPD; new are the capacity presumption, the advance directive, the nominated representative, decriminalisation of a suicide attempt, prohibition of unmodified ECT and the Review Boards.
RIGHTS OF PERSONS WITH DISABILITIES ACT 2016 AND DISABILITY CERTIFICATION	
PERSON WITH DISABILITY VS BENCHMARK DISABILITY (S.2(S), S.2(R))	A person with disability has a long-term impairment which, in interaction with barriers, hinders full participation, with NO percentage threshold; a person with BENCHMARK disability has not less than FORTY per cent of a specified disability, the gateway to reservation and scheme entitlements. The forty per cent attaches to benchmark disability, not to person with disability.
LIMITED GUARDIANSHIP (RPWD S.14)	A district court or designated authority may appoint a LIMITED guardian for joint, supported decision-making, in consultation with and according to the will of the person, for a specific period and decision, total support only where required; contrast the National Trust Act 1999 plenary guardian appointed by the Local Level Committee for its four covered conditions.

ASK	HOLD
CERTIFICATION OF DISABILITY (S.56 TO S.58)	The Central Government notifies the assessment guidelines (s.56); designated certifying authorities issue the certificate (s.57), now valid across the country (s.58(3)); for mental illness the notified tool is IDEAS.
IDEAS COMPUTATION	Score four items (self-care, interpersonal activities, communication and understanding, work) each 0 to 4 and sum to a Total; ADD a duration-of-illness weightage from 1 to 4 to get the GLOBAL score (0 to 20); it is the global score, not the item total, that maps to the band, and forty per cent (global 7, the Moderate band) is the welfare cut-off.
NARCOTIC DRUGS AND PSYCHOTROPIC SUBSTANCES ACT 1985	
NARCOTIC DRUG VS PSYCHOTROPIC SUBSTANCE (S.2(XIV), S.2(XXIII))	A narcotic drug is enumerated in the Act itself (coca leaf, cannabis, opium, poppy straw and all manufactured drugs); a psychotropic substance is one INCLUDED in the Schedule; small versus commercial quantity is fixed by Central Government notification, not by the Act.
IMMUNITY FOR ADDICTS WHO VOLUNTEER FOR TREATMENT (S.64A)	CONDITIONAL, every condition matters: an addict charged under s.27 or with a SMALL-quantity offence who voluntarily undergoes de-addiction at a Government-run or recognised institution shall not be liable to prosecution; it does not reach commercial-quantity offences, and the immunity may be withdrawn if he does not complete treatment (the bar is mandatory, the withdrawal discretionary).
RELEASE FOR TREATMENT (S.39, S.71)	A court may, with the offender's consent, release an addict found guilty under s.27 or a small-quantity offence for de-addiction instead of immediate imprisonment (s.39); Government may establish or recognise de-addiction centres (s.71).
CRIMINAL RESPONSIBILITY AND FITNESS TO STAND TRIAL	
INSANITY EXCEPTION, CURRENT LAW (BNS S.22)	Nothing is an offence done by a person who, at the time, by reason of UNSOUNDNESS OF MIND is incapable of knowing the nature of the act, or that it is wrong, or that it is contrary to law; in force for offences on or after 1 July 2024. It is word-for-word identical to the old Penal Code s.84, which survives only as the historical provision for earlier offences.
BURDEN OF PROOF FOR THE EXCEPTION (BSA S.108)	The accused must prove the exception on the balance of probabilities and the court presumes its absence; the prosecution's proof beyond reasonable doubt is not displaced. Current law, reproducing the old Evidence Act s.105.
M'NAGHTEN RULES (1843)	Presumption of sanity; the defence needs clear proof that, from a defect of reason due to disease of the mind, the accused did not know the NATURE AND QUALITY of the act, or, if he did, did not know it was WRONG. This cognitive right-wrong test is what BNS s.22 tracks.

ASK	HOLD
BROADER TESTS (NOT INDIAN LAW)	The ALI Model Penal Code adds a volitional prong (substantial capacity to appreciate wrongfulness OR to conform conduct); Durham is the product test (the act as the product of mental disease); irresistible impulse is a volitional gloss; Indian courts generally do not accept irresistible impulse unless it defeats knowing the nature or wrongfulness of the act.
DIMINISHED RESPONSIBILITY AND AUTOMATISM (INDIAN POSITION)	India has no general diminished-responsibility defence; the nearest partial defence to murder is grave and sudden provocation, reducing murder to culpable homicide not amounting to murder; automatism arising from a disease of the mind falls within the unsound-mind exception.
ACTUS REUS AND MENS REA	An offence ordinarily needs both a prohibited act and a guilty mind, and the two must concur; the insanity exception works by negating mens rea; strict-liability offences are the exception.
FITNESS TO STAND TRIAL (BNSS S.367, S.368)	When an accused appears of unsound mind and incapable of making his defence, the court first tries that fact on medical and other evidence and postpones proceedings, at the inquiry stage (s.367) or at trial (s.368); current law, corresponding to the old CrPC s.328 and s.329.
NARCOANALYSIS, POLYGRAPH, BRAIN MAPPING (SELVI, 2010)	Compulsory administration violates Article 20(3) against self-incrimination and Article 21 and amounts to cruel, inhuman or degrading treatment; no such test without consent, and even voluntary results are governed by the National Human Rights Commission 2000 guidelines.
MALINGERING	Intentional production or gross exaggeration of symptoms for an EXTERNAL incentive, a condition warranting attention rather than a disorder; detected by inconsistency, atypical or over-endorsed patterns, poor validity-test effort and collateral; distinct from factitious disorder, whose incentive is internal, the sick role.
HOMICIDE AND FILICIDE	Homicide by a person with mental illness is uncommon but over-represented in active psychosis and intoxication; filicide is classified by motive (Resnick: altruistic, acutely psychotic, unwanted-child, accidental and spouse-revenge); neonaticide, killing within the first day, links to denied pregnancy; postpartum psychosis is a high-risk context.
CIVIL CAPACITY: WILLS, CONTRACTS AND MARRIAGE	
TESTAMENTARY CAPACITY (SUCCESSION ACT S.59)	Every person of sound mind who is not a minor may dispose of property by will; an ordinarily insane person may make a will in a lucid interval; none can make a will while, from intoxication, illness or any cause, he does not know what he is doing.

ASK	HOLD
BANKS V GOODFELLOW (1870)	The sound-and-disposing-mind test in four limbs: understand the act of making a will and its effects, the extent of the property, and the claims of those who might expect to benefit, with no insane delusion perverting the disposition; a delusion that does not influence the will does not remove capacity.
CONTRACTUAL CAPACITY (CONTRACT ACT S.11, S.12)	Competence needs majority AND sound mind AND not being disqualified (s.11); sound mind for a contract is the capacity, at that moment, to understand it and form a rational judgment as to its effect on one's interests (s.12), a different test from the wills test.
MARRIAGE, THE VOID OR VOIDABLE ASYMMETRY	Same mental-capacity condition, opposite consequence. Under the Hindu Marriage Act a breach of s.5(ii) makes the marriage VOIDABLE (s.12(1)(b)), valid until annulled; under the Special Marriage Act a breach of s.4(b) makes it VOID (s.24). Do not collapse them.
MARRIAGE, THE DISSOLUTION GROUND (HMA S.13(1)(III))	A different provision from the formation defect: either spouse may seek divorce where the other is incurably of unsound mind or has a mental disorder such that the petitioner cannot reasonably be expected to live with them; the Explanation includes schizophrenia.
VIOLENCE RISK ASSESSMENT	
FROM DANGEROUSNESS TO VIOLENCE RISK	Not a fixed personal trait but a probabilistic, contextual judgment described by its nature, magnitude, imminence and frequency; the clinical task is risk assessment and management, not prediction of an attribute.
RISK FACTORS	Static and historical (previous violence, young age at first violence, male sex, childhood maladjustment) and dynamic (active symptoms, especially threat or control-override and command hallucinations, substance misuse, non-adherence, social instability); previous violence is the single strongest predictor, and risk concentrates in active psychosis with co-occurring substance use.
ACTUARIAL VS STRUCTURED PROFESSIONAL JUDGMENT	Actuarial tools score mechanically (VRAG-R, a 12-item actuarial guide); SPJ tools guide the clinician through empirically supported factors (HCR-20 Version 3, twenty factors across Historical, Clinical and Risk-management domains; START, a dynamic strengths-and-vulnerabilities measure); PCL-R rates psychopathy. Know the family and purpose; the items are proprietary.
MANAGING THE VIOLENT PATIENT	Graded: de-escalation first, then offered oral medication, and only if necessary rapid tranquillisation and time-limited restraint within s.97 (seclusion banned, restraint conditional); longer term, treat the illness, address substance use, support adherence and keep structured follow-up.

References

Every specific in this chapter is bound to one of the sources below, and the count is the number of claim rows each carried. 65 of those rows are statutory and were read at the primary Act on India Code or an equivalent primary text rather than from any textbook summary, because a stale or paraphrased section changes what a clinician is legally obliged to do. The substantive criminal-responsibility law was read at its current form (Bharatiya Nyaya Sanhita section 22 and Bharatiya Sakshya Adhiniyam section 108, in force 1 July 2024), with the historical Indian Penal Code section 84 named as the superseded provision. 79 row(s) are recorded at verified confidence and 12 at partial, the latter authored from established forensic and clinical knowledge and checked by the adversarial content pass rather than bound to a single primary quote. The must-have-papers cross-check was NOT performed for this Paper III chapter, because the paper lists do not yet exist in the intel index; for Paper III the topic bank plus the syllabus scaffolding is the completeness authority. This table records provenance, not proof: it says where each specific came from, not that the chapter's prose uses it correctly, which the content pass and the ship review test.

PAPER III

Forensic ethics, consent and legal procedure

Five bands . one complete notes document

Orientation: forensic ethics and the legal interface

1 · Orientation: forensic ethics and the legal interface

Why this chapter earns its marks. Almost every question in forensic and ethical psychiatry is, underneath, a question about a single person standing in two places at once. The same clinician who sits with a patient in the consulting room may later sit in a witness box and be asked to give an opinion that helps convict that patient, or a different one. These two positions do not merely differ in setting; they impose opposing duties, answer to different masters, and are governed by different rules about what may be said and to whom. The candidate who holds that tension steadily can reason their way through unfamiliar vignettes; the candidate who has only memorised isolated rules cannot.

This opening section is the chapter's **advance organizer**: the map you should carry in your head while you read everything that follows. It asserts nothing new of its own and teaches no section numbers. Its whole job is to give the later material a shape, so that each rule you meet later has a place to sit rather than floating free. The accompanying figure sets out the same structure visually; read it alongside this text.

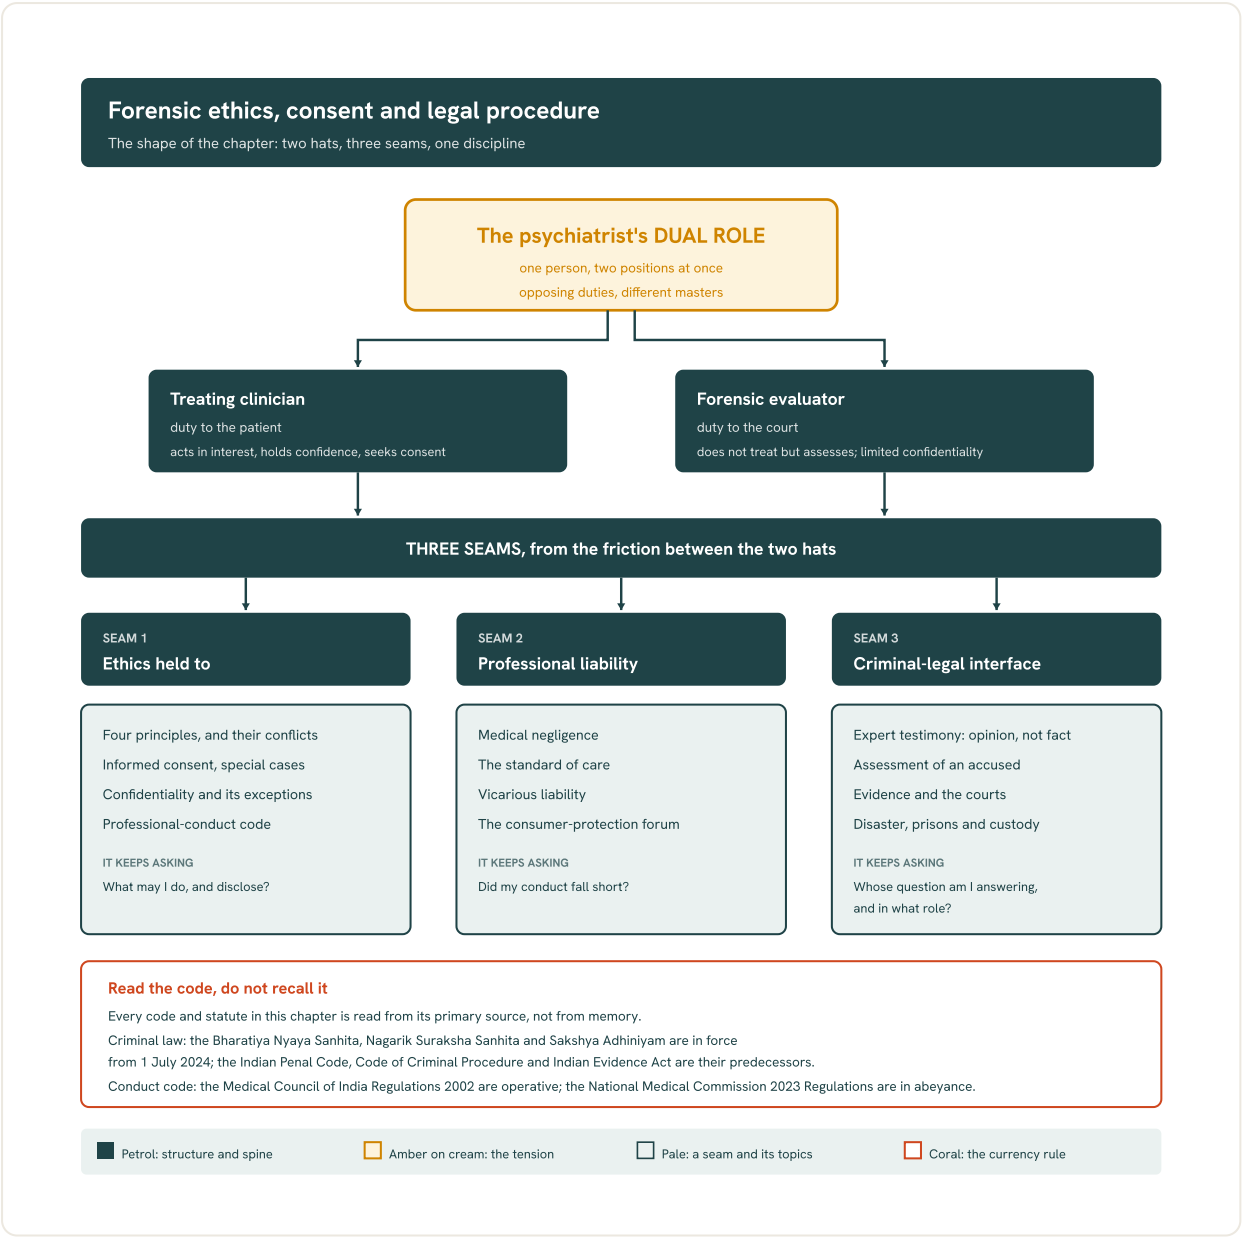

Fig 26.1. The chapter's architecture: one psychiatrist in a dual role, treating clinician on one side and forensic evaluator on the other, and from that friction three seams - the ethics held to, professional liability, and the criminal-legal interface - each read from its primary source with the law current as of 1 July 2024.

1.1 The two hats: the psychiatrist's dual role

The organising tension of this whole chapter is a **dual role**. In one role the psychiatrist is the **treating clinician**, who owes a set of duties to the patient in front of them: to act in that patient's interest, to hold their disclosures in confidence, to obtain their consent before acting. In the other role the psychiatrist is a **forensic evaluator**, who does not treat but assesses, and whose duty runs not to the person being examined but to the court that has asked the question. The forensic evaluator is not the person's doctor, owes them no therapeutic loyalty, and must say plainly, before beginning, that the ordinary clinical duty of confidentiality does not apply and that what is said may be set down in a report for whoever asked for the assessment.

Almost every controversy in the chapter is a friction between these two roles. The obligations that protect a patient in the first role become the very things a court needs the evaluator to set aside in the second. When a treating psychiatrist is dragged into a case about their own patient,

the two hats collide directly, and knowing which hat is being worn at a given moment is what tells you which duty controls.

MNEMONIC

Two Hats, Three Seams

The **two hats** are the treating clinician and the forensic evaluator. From that one tension follow the **three seams** the chapter is stitched along: the ethics a psychiatrist is held to, professional liability, and the criminal-legal interface. Hold the two hats and you can reconstruct the three seams; hold the three seams and you can place any rule the chapter teaches.

1.2 The first seam: the ethics a psychiatrist is held to

The first seam is the ordinary ethical scaffolding of practice, examined more strictly here because the forensic setting stresses it. It runs through the four principles of biomedical ethics and how they conflict; through informed consent and the special situations that complicate it; through confidentiality and, more importantly, the recognised grounds on which confidentiality may be broken; and through professional conduct under the statutory code and the profession's own code of ethics. The recurring exam move in this seam is to take a duty you think is absolute and show you its edge - the point at which a competing duty, or a statutory permission, lets it give way.

1.3 The second seam: professional liability

The second seam is what happens when practice is alleged to have fallen short. This is **professional liability**: the law of medical negligence, the standard of care against which a doctor is judged, the idea of vicarious liability for the acts of others, and the consumer-protection forum through which a patient can pursue a claim for a deficiency in medical service. The seam matters because it converts abstract ethical duty into concrete, enforceable consequence, and because candidates routinely underestimate how far the consumer-protection route reaches into medical practice.

1.4 The third seam: the criminal-legal interface

The third seam is where the psychiatrist meets the criminal justice system: as an expert witness whose opinion evidence must be kept distinct from fact evidence, in the assessment of an accused person, in the rules of evidence and the structure of the courts, and in the special settings of disaster, prisons and custody where a vulnerable population meets a coercive institution. This is the seam where the second hat is worn most consciously, and where the difference between treating and evaluating is not a nicety but the whole point.

SEAM	WHAT IT GOVERNS	THE QUESTION IT KEEPS ASKING
Ethics	Principles, consent, confidentiality, professional conduct	What am I permitted to do, and to disclose?
Professional liability	Negligence, standard of care, the consumer forum	Did my conduct fall below what was owed?
Criminal-legal interface	Expert testimony, assessment of the accused, evidence, custody	Whose question am I answering, and in what role?

1.5 One discipline throughout: the primary source and the currency problem

One habit binds the three seams together. Every code and statute in this chapter is read from its **primary source**, not from a summary or a remembered lecture, because this is precisely the ground that has been shifting under the profession's feet. Two live currency problems run across the whole chapter. The substantive criminal law has been recodified wholesale, so that the older penal, procedural and evidence statutes have given way to their successors, with a savings rule that decides which regime applies to a given case. And the professional-conduct code has its own complication: the long-standing Medical Council of India conduct regulations remain the operative code, while the successor National Medical Commission regulations, though formally notified, have been held in abeyance and are not operative pending a further notification. An answer written from memory of the old law, or from the assumption that the newest notified rule must be the live one, will be confidently wrong.

RULE **Read the code, do not recall it.** On this chapter the currency of the source is itself the examinable content. Name the statute you are relying on, confirm it is the version in force, and check the savings position before you apply it. The forensic seam punishes stale knowledge more than any other part of the syllabus.

TRAP **Citing the superseded criminal statutes as current law.** The Indian Penal Code, the Code of Criminal Procedure and the Indian Evidence Act read as the natural answers because they were the answers for a generation. After the recodification they are historical; the successor codes govern, subject to the savings rule. Candidates lose easy marks by naming the old statute by reflex.

PITFALL

The mirror-image real-world error is to treat the newest *notified* professional-conduct regulations as the live code. The newest notified regulations were themselves held in abeyance by a later amendment, which restored the earlier Medical Council of India code as the operative one, so that is the code a disciplinary body actually applies. Acting on the wrong code is a governance error, not merely an exam slip.

IN INDIA

This is an Indian statutory chapter, and its answers are Indian primary sources that differ from the Western textbook defaults: an Indian criminal law recently recodified, an Indian professional-conduct code with a live-versus-notified split, an Indian consumer-protection route into medical liability, and an Indian confidentiality regime that *permits* proportionate disclosure rather than importing a foreign duty to warn. Where a chapter topic has an Indian answer, that is the answer the examiner wants.

1.6 The edges of the map: what is named here and taught elsewhere

An advance organizer is as much about what lies outside the frame as inside it. Several bodies of law are touched by this chapter but owned by others, and are named here only so you know where they live:

- The Mental Healthcare Act machinery, the criminal-responsibility doctrine with its insanity-defence test and its burden of proof, the disability-rights and narcotics statutes, and the violence-risk instruments belong to the Mental health legislation and forensic psychiatry notes.
- The child-sexual-offences framework, the juvenile justice law and child custody belong to the Child psychiatry: assessment, treatment, services and protection notes.
- The clinical management of substance use in custodial and de-addiction settings belongs to the Substance use disorders notes.

Within this chapter, the material moves from the ethical foundations, through consent and confidentiality, into liability, and out to the criminal-legal interface and its special settings, before drawing the seams back together. Keep the two hats and the three seams in view and the sequence will read as one argument rather than a list.

Every duty in this chapter resolves to one question - what may be disclosed, to whom, and on whose authority - and the answer changes depending on which hat the psychiatrist is wearing.

Professional ethics, consent and confidentiality

2 · Principles of medical ethics (autonomy, beneficence, non-maleficence, justice)

The four principles are the grammar every ethical argument in medicine is written in. When a psychiatrist has to defend a decision - to admit a refusing patient, to withhold a diagnosis a family demands, to ration a scarce bed - the reasons that carry weight almost always reduce to four familiar considerations: the patient's right to decide for themselves, the duty to do them good, the duty not to harm them, and the duty to treat people fairly. These are not rules that dictate answers. They are the standing obligations a clinician must be able to name and weigh,

and an examiner who asks about medical ethics is asking whether the candidate can do that weighing out loud.

The marks here are for precision and for the hard part, which is conflict. Any candidate can list the four principles; the discriminating answer shows that they are separate obligations that routinely pull against one another, that none automatically defeats the others, and that resolving a real case is a matter of judged balance rather than a lookup. This account defines each principle at the depth the exam expects, then shows how they collide inside an ordinary psychiatric decision and how a defensible clinician reasons through the collision. The professional codes that translate these principles into enforceable conduct rules, and the specific law on consent, confidentiality and negligence, are each owned elsewhere in this chapter and are named here, not re-taught.

4

PRINCIPLES OF BIOMEDICAL ETHICS

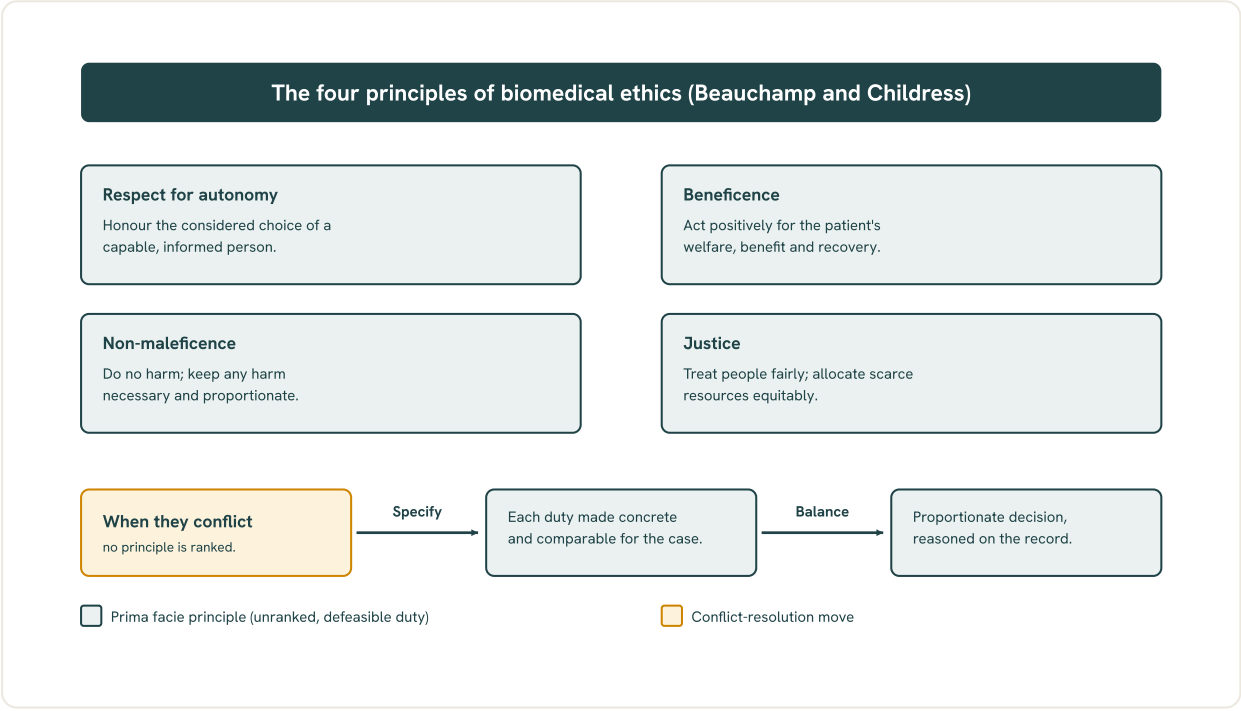

Fig 26.2. The four principles of biomedical ethics (Beauchamp and Childress) as unranked prima facie duties; at conflict, specify each then balance them into a proportionate, recorded decision.

2.1 The framework: four prima facie principles

The dominant framework in medical ethics is the four-principles approach set out by **Beauchamp and Childress**, who argued that a small set of general obligations, drawn from the morality that thoughtful people across traditions already share, can organise almost any clinical ethical problem. On this account there are **four** such obligations: respect for autonomy, beneficence, non-maleficence and justice. Their appeal is practical. They are neutral between the deeper moral theories a clinician may privately hold, so a consequentialist and a duty-based colleague can reason together in the same terms.

The single most important structural fact about the framework is that each principle is a **prima facie** obligation: it binds absolutely unless, in the particular case, it is outweighed by a competing obligation of equal or greater force. A prima facie duty is real and demanding, but it is defeasible. This is what separates the four principles from a code of commandments. There is no fixed ranking in which autonomy always beats beneficence, or non-maleficence always beats justice; the weight each carries is settled case by case. A candidate who writes that "autonomy is the highest principle" has misunderstood the model at its root, because a framework of prima facie obligations has no permanent highest.

MNEMONIC

A Bee Never Judges

The four principles of biomedical ethics: **A**utonomy (respect the capable patient's own choice), **Be**neficence (act for their good), **N**on-maleficence (do not harm), **J**ustice (treat people fairly and distribute resources justly). The phrase fixes the list; it deliberately encodes no ranking, because the framework sets none.

RULE **Each principle is a prima facie obligation with no fixed priority, so ethical reasoning is balancing, not ranking.** A principle can only be overridden by a competing principle that carries greater weight in the specific circumstances, and the clinician must be able to state which principle yielded to which, and why. An answer that resolves a dilemma by declaring one principle supreme has replaced the framework with a hierarchy the framework rejects.

2.2 Respect for autonomy

Respect for **autonomy** is the obligation to honour the considered choices of a person who is competent to make them. Its positive content is not merely leaving the patient alone; it is the duty to enable genuine self-determination - to tell the truth, to disclose what a reasonable patient needs in order to decide, to protect against coercion, and then to abide by the decision a capable person reaches, including a decision the clinician thinks unwise. Autonomy is the ethical engine behind the law of informed consent, whose elements, the assessment of decision-making capacity, and the special situations in which consent is complicated are set out in this chapter's account of informed consent and are not restated here.

Two clarifications earn marks. First, respect for autonomy presupposes capacity; it is a duty owed to a person who has the capacity to make the particular choice, so a decision made without that capacity is not an exercise of autonomy to be respected but an absence of it to be managed. The functional test for that capacity, and its statutory form under the Mental Healthcare Act, belong to this chapter's account of informed consent and to the Mental health legislation and forensic psychiatry notes, and are named here rather than stated. Where a patient lacks capacity, the clinician does not abandon autonomy but shifts to protecting the person's known will and preferences, a reframing the Mental Healthcare Act makes central and whose machinery belongs to the Mental health legislation and forensic psychiatry notes. Second, autonomy is not the same as getting whatever one asks for: a patient may refuse an offered treatment, but the right to

demand a treatment that is not indicated is not part of the principle, because the clinician's own duties of beneficence and non-maleficence remain in force.

2.3 Beneficence

Beneficence is the positive obligation to act for the patient's benefit - to prevent and remove harm, and to promote the patient's welfare and interests. It is the principle that makes medicine a helping profession rather than a merely technical one. In psychiatry beneficence is unusually demanding because the conditions treated can themselves impair the patient's ability to seek or accept help, so acting for the patient's good sometimes means acting before, or even against, what the patient currently says they want.

That is precisely where beneficence becomes dangerous, and the discrimination the exam wants is between beneficence and **paternalism**. Beneficence exercised over a capable patient's contrary wishes is paternalism, and paternalism is defensible only in narrow circumstances - broadly, where the patient's capacity for the decision is genuinely absent or compromised, and the benefit at stake is significant. When a clinician overrides a capable refusal in the name of the patient's own good, they have not applied beneficence cleanly; they have set beneficence against autonomy and must justify the trade. The habit of reaching for "it was in the patient's best interests" as though beneficence settled the matter is the commonest way this principle is abused.

> **PITFALL**
>
> Invoking beneficence to override a capable patient's refusal without ever naming the conflict. In real wards, "it is for their own good" is used to close a decision that the four-principles framework says is still open: acting for the patient's good against their competent choice is not beneficence operating alone, it is beneficence defeating autonomy, and it needs the higher justification that overriding a capable choice always demands. Clinicians who never notice they have made that trade drift into routine paternalism and cannot defend the individual decision when it is later questioned.

2.4 Non-maleficence

Non-maleficence is the obligation not to inflict harm, the principle behind the old maxim primum non nocere, first do no harm. It is often paired with beneficence, and in Beauchamp and Childress's own account the two are distinct obligations rather than two faces of one: beneficence requires positive acts to help, while non-maleficence sets a floor by forbidding acts that harm. The distinction matters because the two carry different stringency. The duty not to harm is generally the more stringent - a clinician is expected to refrain from harming everyone, always, whereas the duty to actively benefit is owed within the specific therapeutic relationship and is bounded by what is feasible and proportionate.

Non-maleficence has sharp teeth in psychiatry, where the treatments themselves carry real burdens: the metabolic and neurological costs of medication, the harms of seclusion and restraint, the stigma that a careless disclosure can cause. Because almost every effective intervention carries some risk of harm, the principle is not a prohibition on all risk but a demand that harm be necessary, proportionate to the expected benefit, and reduced to the least that

achieves the aim - the ethical root of the least-restrictive-option requirement that runs through mental health law. The professional liability that follows when a clinician causes harm by falling below the standard of care - the law of negligence - is the subject of this chapter's account of professional negligence and is named, not developed, here.

The framework also supplies the tool for the case where doing good and doing harm are inseparable: the doctrine of **double effect**, by which an action with both a good intended effect and a harmful foreseen one may be permissible only when strict conditions hold together:

- the act itself is good, or at least morally neutral, and not wrong in its own right;
- the harmful effect is genuinely not the aim but a tolerated side effect;
- the good effect is not achieved by means of the harm; and
- the good is proportionate to the harm risked.

It is the reasoning that lets a clinician offer a treatment whose necessary benefit comes with a foreseen burden, without thereby intending the burden.

2.5 Justice

Justice is the obligation to treat people fairly - to give each their due, to treat like cases alike, and to distribute the benefits and burdens of care equitably. It is the principle that looks beyond the individual consultation to the patient's standing relative to others, and it is the one clinicians are least trained to reason about, which is exactly why it is examined. In its distributive form, **distributive justice** governs how a genuinely scarce resource - an inpatient bed, a slot in a specialist clinic, staff time, a costly medication in a public system - is allocated when not everyone who could benefit can be served.

Justice in psychiatry carries an added weight because of the population served. People with mental illness are among the most likely to face discrimination, to be denied parity with physical health in funding and access, and to have their preferences discounted; a serious commitment to justice therefore includes non-discrimination and the protection of a vulnerable group's fair claim on care, not merely the arithmetic of dividing a resource. Fairness also has a procedural dimension: an allocation decision is more defensible when the criteria are explicit, consistent and applied without regard to a patient's social worth.

PRINCIPLE	CORE OBLIGATION	WHAT IT PROTECTS	SIGNATURE TENSION	PSYCHIATRIC APPLICATION
RESPECT FOR AUTONOMY	Honour the considered choice of a capable person	Self-determination, truth, freedom from coercion	Against beneficence when a capable patient refuses help	Consent to and refusal of treatment; enabling choice where capacity is intact
BENEFICENCE	Act positively for the patient's welfare	The patient's interests and recovery	Against autonomy; slides into paternalism if it overrides a capable choice	Treating a disorder that impairs the will to be treated
NON-MALEFICENCE	Do not inflict harm; keep harm necessary and proportionate	The patient's safety from iatrogenic harm	Against beneficence when the helpful act also burdens	Medication burden, seclusion and restraint, least restriction
JUSTICE	Treat people fairly and allocate resources equitably	Equity, non-discrimination, parity of the vulnerable	Against beneficence to the individual when the resource is shared	Bed and clinic rationing; parity for mental illness

2.6 How the principles conflict, and how a clinician resolves it

The framework earns its keep at the point of conflict, not in the list. Because each principle is prima facie and none is ranked above the rest, a real case can present two or more principles that cannot all be satisfied, and the framework does not resolve this by producing a winner from a formula. It resolves it by two disciplined moves. The first is **specification**: taking an abstract principle and making it concrete for the situation, so that "respect autonomy" becomes "abide by this patient's refusal of this medication given their intact capacity to make it", narrowing a vague obligation into one that can actually be acted on and compared. The second is **balancing**: weighing the specified obligations against each other in the particular circumstances to decide which should prevail here.

Balancing is not licence to prefer whichever principle the clinician favours. A defensible override of one principle by another should meet recognisable conditions: the overriding principle must have a realistic prospect of achieving its aim, no less restrictive action would achieve it, the harm to the overridden principle is the least necessary, and the balance of benefit over harm is proportionate. Set out this way, "I decided on balance" becomes an argument that can be examined and defended.

- **Specify each principle** for the actual patient and decision, so the obligations are concrete enough to compare rather than slogans.
- **Identify the genuine conflict** - which specified obligations cannot both be honoured - rather than pretending one principle simply does not apply.
- **Weigh them** against the conditions above: prospect of success, necessity, least infringement, proportionality.

- **Record the reasoning**, naming which principle yielded to which and why, because a balancing judgement is only as defensible as the account that can be given of it.

TRAP **Treating the four principles as a fixed hierarchy, usually with autonomy on top.** Candidates resolve a dilemma by asserting that autonomy always prevails, or that beneficence does, and stop. The framework is explicit that the principles are prima facie and unranked; the whole task is to show the specification and the balance, not to crown a winner. An answer that names a permanent top principle scores below one that shows two principles in genuine tension and reasons to a proportionate resolution.

2.7 The conflicts in a psychiatric decision

Psychiatry concentrates the classic conflict of medical ethics into its sharpest form, because the disorders it treats can impair the very capacity on which respect for autonomy depends. The signature tension is autonomy against the paired duties of beneficence and non-maleficence: a patient whose illness drives a refusal that threatens their health or safety. The clinician who simply defers to the stated wish may abandon a patient who cannot, in this moment, choose freely; the one who simply overrides it may trample a capable person's right to decide. The framework insists that the decision turns first on capacity - the hinge that determines whether there is an autonomous choice to respect at all - and that assessment, together with the legal thresholds for acting without consent, belongs to this chapter's account of informed consent and to the Mental health legislation and forensic psychiatry notes, and is applied here rather than re-derived.

The conflict rarely stays a clean two-way contest. Non-maleficence enters through the harms of the very interventions that beneficence recommends, so that admitting or medicating a refusing patient to do them good also imposes the burdens of coercion and side effect that the duty not to harm requires be minimised - which is the ethical source of the demand that the least restrictive effective option be used. Justice enters whenever the resource is shared: the bed given to one acutely unwell patient is a bed denied another, so beneficence to the individual is checked by fairness to the population. A mature answer to a psychiatric ethics question therefore does not pick a principle; it maps which principles are engaged, shows where they conflict, and reasons to a proportionate resolution that respects capacity, uses the least restriction, minimises harm and remains fair.

IN INDIA

Indian mental health law has taken a deliberately autonomy-forward turn, and the four principles have to be read in that light. The Mental Healthcare Act reframes the autonomy of a person with mental illness around their will and preferences and supported decision-making rather than around substitute judgement made over their head, and it embeds least restriction and non-discrimination as legal duties, not merely ethical aspirations - the statutory machinery for all of which belongs to the Mental health legislation and forensic psychiatry notes. Justice also bites harder in the Indian setting, where a public system serves large numbers with scarce inpatient and specialist resources and where parity for mental illness against physical illness is still being won, so distributive fairness is a live daily judgement and not a seminar abstraction. The principles are universal; their weighting in Indian practice is shaped by a statute that puts the patient's own will near the centre and by a resource reality that keeps justice in the room.

GOOD TO REMEMBER

When a case feels like an ethical knot, name the four principles for that specific patient before reaching for a conclusion: what does respecting this person's choice require, what would do them good, what would harm them, and what does fairness to others demand. The knot almost always turns out to be two of the four in genuine tension, most often autonomy against beneficence, with capacity as the hinge. Decide which principle should yield, choose the least restrictive way to honour the one that prevails, and write down the reasoning. A decision reasoned that way is far easier to defend than one reached by instinct and dressed up afterwards.

The four principles - respect for autonomy, beneficence, non-maleficence and justice - are prima facie obligations with no fixed ranking, so medical ethics is the balancing of principles that conflict, not the application of one that wins; in psychiatry the signature conflict is autonomy against beneficence and non-maleficence, turning on the patient's capacity, and the defensible decision is the one that respects a capable choice, does good, minimises harm, stays fair, and is reasoned on the record.

3 · Informed consent in psychiatry (elements, capacity, special situations)

Consent is where the patient's autonomy stops being an abstraction and starts governing what a doctor may lawfully do. Nothing a psychiatrist proposes, from a first prescription to admission to electroconvulsive therapy, is lawful merely because it is clinically indicated; it is lawful because the person it is done to has agreed, or because a specific legal exception has displaced the need for agreement. Informed consent is how that agreement is made real, and the examinable weight of the topic sits in its structure: what makes a consent valid rather than a formality, how the capacity to give it is judged, how much the patient must be told, and what happens where the ordinary rule cannot apply.

Marks are lost when a candidate treats consent as a signature on a form. The signed form is evidence that a conversation happened; it is not the consent, and a form signed by a patient who did not understand, was not free, or was not told what mattered is worth nothing in law. This

account sets out the three elements of a valid consent as the Indian courts define them, the standard of disclosure, the scope to which a consent is confined, the documentation the conduct code requires, and the special situations where consent is modified or displaced. Where the Mental Healthcare Act's own machinery governs, this account names the provision and points to the Mental health legislation and forensic psychiatry notes for its full working.

2008	3	19	4
SAMIRA KOHLI, THE INDIAN AUTHORITY ON REAL AND VALID CONSENT	ELEMENTS OF A VALID CONSENT: CAPACITY, VOLUNTARINESS, ADEQUATE INFORMATION	INFORMED-CONSENT REGULATION IN THE MOST RECENTLY NOTIFIED CONDUCT CODE	MENTAL HEALTHCARE ACT SECTION STATING THE STATUTORY CAPACITY TEST

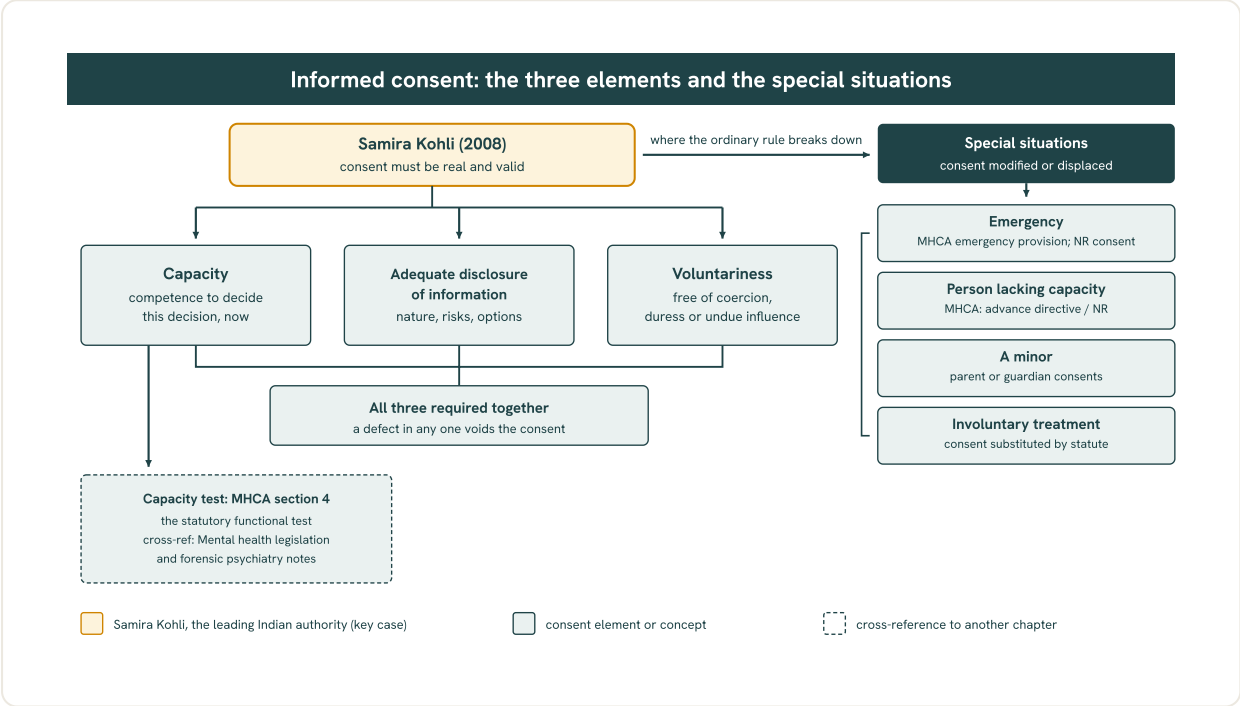

Fig 26.3. Informed consent has three cumulative elements - capacity, adequate disclosure of information and voluntariness - all required together for a valid consent (Samira Kohli, 2008), with a defined alternative for each special situation where consent is modified or displaced.

3.1 What informed consent is, and why the form is not the consent

Informed consent is a patient's voluntary, competent and informed agreement to a proposed procedure, given before it is begun. It rests on two footings that reinforce each other. Ethically it is the operational expression of respect for autonomy, the principle whose full treatment belongs to this chapter's account of the principles of medical ethics: a person has the right to decide what is done to their own body, and consent is how that right is exercised. Legally, treating a competent adult without valid consent is not merely poor practice but a wrong: it can found a claim in negligence where the failure lies in inadequate disclosure, and can amount to assault and battery where there was no agreement to the touching at all.

The conceptual correction to make early is that consent is a process, not a document. The conversation in which the clinician explains and the patient asks, weighs and decides is the consent; the signature merely records that it took place. A form can be exhaustive and the consent still invalid where the patient lacked capacity, was pressured, or was told nothing that

mattered, and a consent can be valid though its record is thin. The document protects the clinician evidentially but neither creates nor cures the underlying agreement, which is why the elements below attach to the patient's actual state of mind and freedom, not to the paperwork.

RULE **A consent is lawful only if it is real and valid, which means the patient had the capacity to decide, decided voluntarily, and decided on adequate information.** All three must be present together; a defect in any one voids the consent however well the other two are satisfied. The signature is evidence that consent was sought, not proof that it was valid.

3.2 The three elements: Samira Kohli

The Indian leading authority on what makes a treatment consent valid is **Samira Kohli**, decided in **2008**. The court held that a doctor must seek and secure the patient's consent before commencing treatment, and that the consent obtained must be real and valid. It then unpacked that phrase into **three** requirements that every candidate should be able to state and defend: the patient must have the capacity and competence to consent; the consent must be voluntary; and it must rest on adequate information about the nature of the treatment, so that the patient knows what they are agreeing to.

The value of the case is that it converts a vague ideal into a checklist that can be tested against the facts, with each element answering a different question. **Capacity** asks whether this patient, at this moment, can make this decision at all. **Voluntariness** asks whether the decision was the patient's own or the product of pressure. **Adequate disclosure** asks whether the patient was given enough to decide on. The three are cumulative and independent, and the following subtopics take each in turn.

MNEMONIC

Capable, Free, Informed, and Specific

A consent is valid only if the patient is **Capable** of deciding, decides **Free** of coercion, decides **Informed** by adequate disclosure, and the agreement is **Specific** to the procedure actually done. The first three are the elements of validity; the fourth is the limit on its scope, taken up below.

3.3 The first element: capacity to decide

Capacity is the ability to make a particular decision at the time it must be made, and three properties of it are examinable. It is **functional**: judged by the patient's actual reasoning about the decision in front of them, not by their diagnosis, their age, or how others rate the wisdom of the outcome. It is **decision-specific and time-specific**: a person may have capacity for a simple choice and lack it for a complex one, and may lack it in the morning and regain it by evening, so capacity is assessed for this decision now, never certified once for all purposes. And it is **presumed**: every adult is taken to have capacity unless the contrary is shown, so the burden lies on whoever asserts incapacity, and mental illness never by itself removes it.

The Mental Healthcare Act gives this a statutory form. At section **4** it provides that every person, including a person with mental illness, shall be deemed to have the capacity to make treatment decisions if they can understand the information relevant to the decision, appreciate the

reasonably foreseeable consequences of deciding or of not deciding, or communicate the decision, which is the Act's own disjunctive formulation. Two features of the statutory test are the ones candidates get wrong, and both matter directly to consent. The full working of the section, and how capacity interacts with advance directives, nominated representatives, admission and the review boards, belongs to the Mental health legislation and forensic psychiatry notes; what the consent doctrine needs from it is the functional standard and the discriminations below.

TRAP **A decision that looks wrong does not prove incapacity, and the statutory abilities are read disjunctively, not as a set all of which must be present.** Candidates infer incapacity from an unwise refusal, but a competent patient is entitled to make a decision others consider mistaken, and a choice perceived as inappropriate does not by itself negate capacity. The second error is to treat the statutory abilities as a conjunctive checklist; in the bare text of the Act they are joined by "or", and capacity is a rebuttable deeming rather than a hurdle the patient must clear.

3.4 The second element: voluntariness

Voluntariness means the decision was the patient's own, made free of coercion, duress and undue influence. It is the element most easily overlooked because it leaves no trace on a form, yet it is the one most often compromised in psychiatric settings, where the pressures are structural rather than crude. The test is whether the patient's choice was improperly controlled, not whether a consequence was mentioned: a patient pressured by a threat that refusal will be punished, or by a controlling inducement, may not be deciding freely even where no crude threat is spoken, whereas explaining a genuine clinical consequence of refusal, or offering a proportionate incentive, does not by itself negate voluntariness. Family pressure is a particular hazard in Indian practice, where treatment decisions are frequently made collectively and the identified patient may have the least voice in the room.

The clinician's task is not only to avoid applying pressure but to notice and, where possible, neutralise it: separating the consent conversation from any implied consequence, giving the patient a genuine and unpenalised option to decline, and staying alert to the difference between a family reaching a shared decision and a family overriding the patient's own. The distinction between a voluntary agreement and a merely compliant one is the distinction the law draws between a valid consent and an invalid one.

3.5 The third element: adequate disclosure and its standard

The third element asks how much the clinician must tell the patient, and here the Indian courts made a deliberate choice between two rival standards. One is the professional or **Bolam** standard, which measures disclosure against what a responsible body of skilled practitioners in the field would regard as normal and proper. The other is the patient-centred **Canterbury** standard, which measures it against what a reasonably prudent patient would want to know. In Samira Kohli the court adopted the former: the information a doctor must furnish to secure consent need not reach the more stringent degree required by the patient-centred approach, but should be of the extent accepted as normal and proper by a responsible body of skilled and experienced practitioners in that field, adjusted to the patient's condition and the treatment's risks.

The practical content of adequate disclosure follows from this: the nature and purpose of the proposed treatment, its risks and likely consequences, the reasonable alternatives including doing nothing, and enough about the illness for the choice to make sense. Two points sharpen it. The standard is not a licence to tell the patient as little as the profession can get away with; it sets a floor of what a responsible practitioner would disclose, and defensive minimalism does not meet it. And the measure is relevance to the decision, not exhaustiveness; a patient buried in every conceivable rare risk is no better placed to decide than one told too little.

AXIS	PROFESSIONAL STANDARD (BOLAM, REAL CONSENT)	PATIENT-CENTRED STANDARD (CANTERBURY)
THE QUESTION ASKED	What would a responsible body of practitioners disclose?	What would a reasonably prudent patient want to know?
WHOSE VIEWPOINT SETS THE MEASURE	The profession's accepted practice	The reasonable patient's information needs
RELATIVE DEMAND ON THE DOCTOR	Lower; the accepted and proper extent for the field	Higher; a more stringent degree of disclosure
POSITION ADOPTED IN INDIAN LAW	Adopted in Samira Kohli as the governing standard	Expressly not required to the stringent degree it sets

3.6 The scope of consent: specific, not general

A valid consent authorises only what it was given for. This is **specific consent**, and Samira Kohli states it with unusual clarity: consent given for a diagnostic procedure cannot be treated as consent for therapeutic treatment, and consent given for one specified treatment procedure will not be valid for conducting some other procedure. A patient who agreed to an assessment has not agreed to whatever the assessment reveals may be needed.

The court closed the obvious escape route as well. The fact that an unauthorised additional procedure turned out to benefit the patient, saved time or expense, or spared future suffering is no defence to an action in negligence or in assault and battery. Benefit does not backfill absent consent. For psychiatry the point bites wherever one intervention opens onto another; each step requires its own agreement, and the reasoning that "it was for the patient's good" is precisely the reasoning the court rejected.

> **GOOD TO REMEMBER**
>
> Treat consent as reopened whenever the plan moves beyond what the patient actually agreed to. If the working diagnosis, the drug class, the route, or the setting of care changes materially, consent afresh for the new proposal rather than reading the old agreement forward: a short documented second conversation is cheaper than defending an intervention the patient never agreed to.

3.7 Documentation and the conduct code

The professional-conduct code turns the doctrine into a documentation duty. The most recently notified conduct regulations set out informed consent at regulation **19**: before any diagnostic or therapeutic procedure or operation the registered medical practitioner should obtain the patient's

signed documented informed consent; where the patient is unable to consent, the consent of the legal guardian or a family member must be taken; an operation that may result in sterility requires the consent of both spouses; and assisted-reproduction procedures require the written consent of the female patient, the spouse and the donor. The modal verbs are not interchangeable and carry the marks: the practitioner should obtain the patient's consent, the guardian's consent must be taken where the patient cannot, and both spouses' consent is required for a sterilising operation.

A currency caution attaches to this. Whether the most recently notified regulations are the edition currently in force is a separate question, settled in this chapter's account of the professional-conduct codes; the operative professional-conduct code remains the earlier one, and the most recent regulations, though notified, were held in abeyance and are not yet in force. Both editions impose a documented consent duty, but the precise scope and wording of each edition's consent provision belong to this chapter's account of the professional-conduct codes; what matters here is that an answer presenting the most recent regulations as the live code states a currency that does not hold.

PITFALL

Citing the most recently notified professional-conduct regulations as the operative code. They were notified and then held in abeyance, and the earlier professional-conduct code remains the one in force; naming the newer set as live misstates the governing law even though the substance of the consent duty is largely unchanged. Name the provision actually in force, and defer any contested currency to this chapter's account of the professional-conduct codes rather than asserting it in passing.

3.8 The special situations

The elements describe the ordinary case; the marks cluster in the situations where the ordinary case breaks down. Four recur, and each modifies or displaces one element of consent rather than abolishing the requirement.

- **Emergency.** Where a patient needs immediate treatment to avert death or serious harm and cannot give consent, the practitioner should still try to obtain it, and if that is not possible must act in the patient's best interest and record the basis for doing so. Where the Mental Healthcare Act governs an emergency in a person with mental illness, the Act's own emergency-treatment provision supplies the rule rather than the general one: it requires the informed consent of the nominated representative where one is available, and attaches its own indications, time limit and excluded treatments; the full working of that provision belongs to the Mental health legislation and forensic psychiatry notes. The exception is necessity and is bounded by it: it authorises only what the emergency requires, not a general power to treat without agreement.
- **The person who lacks capacity.** Where an adult cannot give a valid consent, the most recently notified conduct regulations direct that the consent of the legal guardian or a family member be taken, subject to the currency caution above, and the decision must serve the

patient's interests rather than the convenience of others. Where the Mental Healthcare Act governs, a family member is not a generic substitute decision-maker: the advance directive carries the person's own earlier choice forward, and the nominated representative supports the person's decision-making and gives consent in their place only where a provision of the Act expressly says so; the full working of both belongs to the Mental health legislation and forensic psychiatry notes. Capacity being decision-specific and often fluctuating, the clinician should reassess it and return the decision to the patient once it is regained.

- **Minors.** A child below the age at which the law recognises a valid consent cannot give one, and consent is taken from the parent or legal guardian on the child's behalf, again in the child's interest. The statutory age thresholds and the child-protection framework, including the law on child sexual offences and juvenile justice, belong to the Child psychiatry: assessment, treatment, services and protection notes.
- **Consent under involuntary treatment.** Involuntary admission and treatment are precisely the situation in which ordinary consent has been lawfully displaced by a statutory framework, which substitutes its own safeguards, the nominated representative and independent review, for the patient's contemporaneous agreement, while the advance directive preserves the person's own earlier choice rather than replacing it. The mechanics of that framework belong to the Mental health legislation and forensic psychiatry notes, and its ethical frame to this chapter's account of the ethics of involuntary treatment and restraint; the consent point is that involuntary treatment is not consent-free but consent-substituted, and the safeguards are what police the substitution.

Consent to research, and the distinct criminal-law meaning of consent in sexual-offences law, are separate constructs treated in this chapter's accounts of the ethics of research and of sexual-offences law; each invokes the clinical elements set out here but adds rules of its own.

IN INDIA

The Indian consent doctrine is anchored in a single case and a statute a candidate should be able to pair. Samira Kohli supplies the three elements and the choice of the professional standard of disclosure over the more demanding patient-centred one, so an Indian answer asserting a Canterbury-level duty overstates the law. The Mental Healthcare Act supplies the statutory, functional capacity test and the framework under which consent is displaced in involuntary care, and the conduct code supplies the documentation duty. Together they make consent in Indian psychiatry a valid agreement properly recorded, with the statute governing the situations where agreement cannot be obtained.

TRAP **Reciting the three elements while omitting the special situations, or treating a signed form as conclusive proof of a valid consent.** The question on consent almost always turns on the hard case, the emergency, the incapacitated adult, the minor, the involuntary patient, so an answer that stops at capacity, voluntariness and disclosure has answered half the question. The paired error is evidential: producing a signed form as if it settled validity, when a form signed without capacity, freedom or adequate information is no consent at all.

A consent is lawful only if it is real and valid, meaning the patient had the capacity to make this decision, decided voluntarily, and decided on adequate information, and it authorises only the specific procedure agreed to; where the patient cannot give it, the emergency, the incapacitated adult, the minor and the patient under involuntary treatment each substitute a defined alternative rather than dispensing with the requirement.

4 · Confidentiality and its limits (duty to warn, Tarasoff)

Confidentiality is the promise that makes psychiatry possible. A patient tells a psychiatrist things they may never have said aloud, and does so only because they trust that what is spoken in the consulting room stays there. That trust is the working condition of honest disclosure, which is the raw material of every assessment and treatment decision, so the law and the professional codes treat confidentiality as a default duty the clinician owes, not a favour the clinician grants. The duty is not absolute, however, and the examinable heart of this topic is the exact shape of its limits: when the clinician may lift the veil, on whose authority, and how far.

Marks are lost in two opposite directions: one candidate treats confidentiality as sacrosanct and freezes when a patient names a person they mean to harm, another treats any hint of risk as a licence to broadcast the record. Both misread a rule that is conditional and whose conditions are specific. This account sets out the default duty, the principal grounds on which a disclosure is permitted, the American case that gave the world the language of a duty to warn, and the very different Indian position, in which a protective disclosure to an endangered other is permitted rather than commanded, alongside the separate mandatory-reporting duties that particular statutes impose in their own defined situations. Where the Mental Healthcare Act's own internal machinery is concerned, this account names the provision and points to the Mental health legislation and forensic psychiatry notes for its full working.

1976 TARASOFF, THE UNITED STATES ORIGIN OF THE DUTY TO PROTECT	**1998** MR X V HOSPITAL Z, THE INDIAN AUTHORITY ON PROTECTIVE DISCLOSURE	**23** MENTAL HEALTHCARE ACT SECTION, THE STATUTORY RIGHT TO CONFIDENTIALITY	**24** PROFESSIONAL-CONDUCT REGULATION ON CONFIDENTIALITY

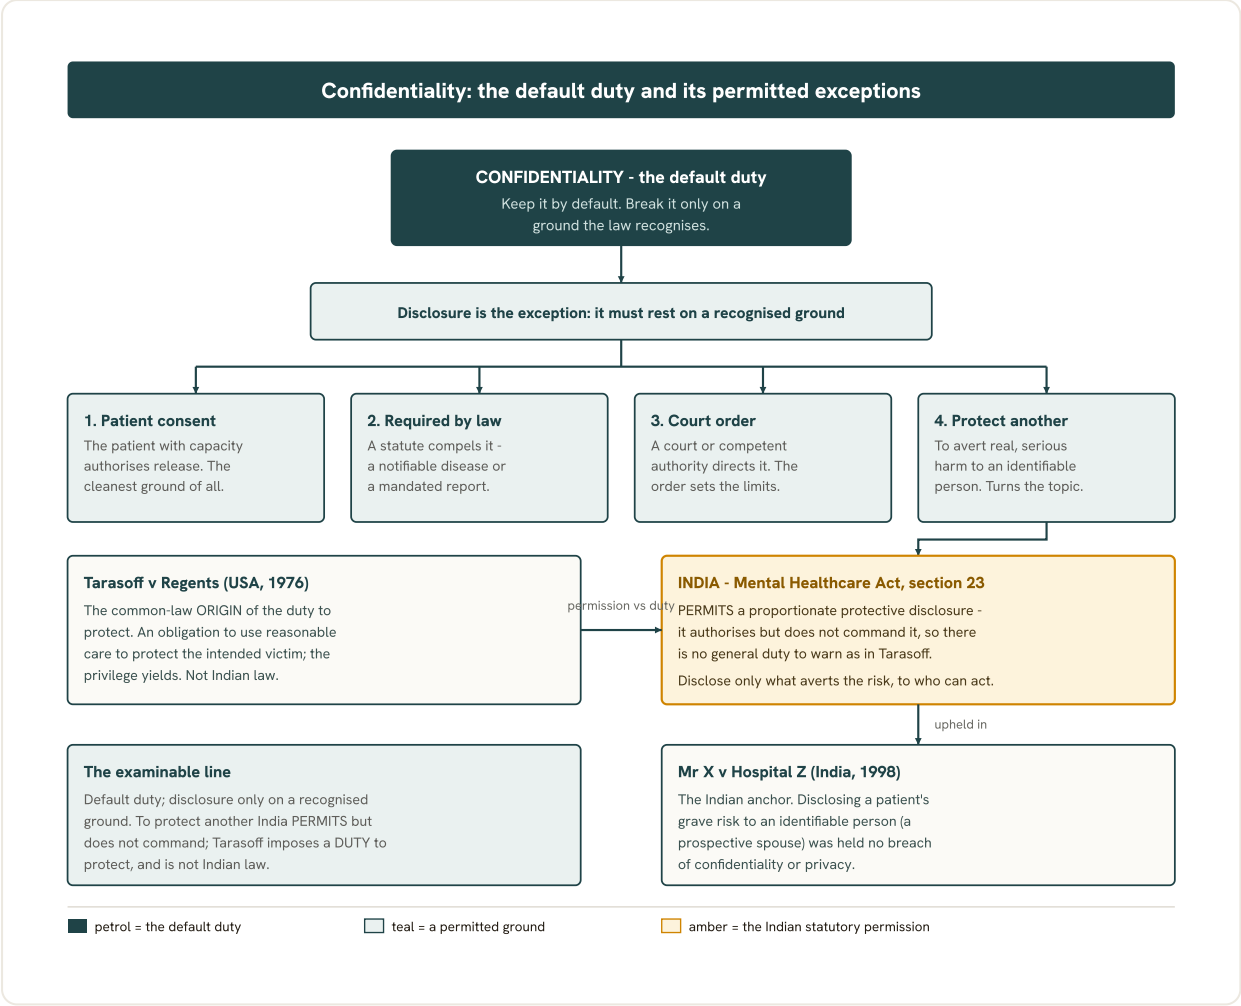

Fig 26.4. Confidentiality is a default duty that yields only on a recognised ground, principally consent, a requirement of law, a court order, or protecting an identifiable other, and for that last ground India permits but does not command disclosure, unlike the United States Tarasoff duty to protect the intended victim, with Mr X v Hospital Z holding a protective disclosure to a person at real risk no breach.

4.1 The default duty and where it comes from

At its core, **confidentiality** is the obligation not to disclose information a patient shares in the course of care to anyone outside that care without a justification the law recognises. It rests on more than one footing. Ethically it protects the patient's autonomy and privacy and secures the trust without which candour collapses; legally it is a duty imposed by both statute and the conduct code, and a serious breach can expose the clinician to complaint and to a civil claim.

Two sources give the duty its force in Indian practice. The statutory source is the Mental Healthcare Act, whose section **23** gives a person with mental illness a right to confidentiality over their mental health, mental healthcare and treatment, and places a corresponding duty on every health professional to keep that information confidential, subject to defined exceptions. The professional source is the medical conduct code. The most recently notified conduct regulations state the duty at regulation **24**: every communication between a practitioner and a patient shall be kept confidential and shall not be revealed except in stated circumstances. Whether that most recent edition is the one currently in force is a separate currency question, settled in this chapter's account of the codes of professional conduct; the duty is stated in the same mandatory terms across the editions and in the statute, so the doctrine does not turn on which edition governs.

One distinction should be fixed at the outset. Confidentiality is the clinician's ethical and statutory duty not to disclose. **Testimonial privilege** is a separate, courtroom creature: whether a clinician can be compelled to testify to what a patient said, and the rules that govern it. Both concern keeping a patient's words private, but they answer to different masters, confidentiality to the codes and the Act, privilege to the law of evidence. What the rules of evidence permit in the witness box is taken up in this chapter's treatment of the expert witness and the rules of evidence; the duty examined here is the clinical one.

RULE **Confidentiality is the default, and disclosure is the exception that must find a specific footing.** The clinician does not need a reason to keep a confidence; they need a reason the law recognises to break one. Every lawful disclosure must rest on a recognised ground, and a disclosure that cannot name its ground is a breach, however well meant.

4.2 When the veil may be lifted: the principal grounds

Because disclosure must justify itself, the circumstances that justify it form a defined set of recognised grounds, each carrying its own conditions. The conditions are where the marks sit, because collapsing a conditional rule to its headline is how a candidate loses the point. The principal grounds are these, and the Mental Healthcare Act's own statutory list of exceptions is fuller than this teaching set and is set out in the Mental health legislation and forensic psychiatry notes.

- **The patient's own consent.** A patient with capacity may authorise the release of their information, the first and cleanest ground of all. What consent requires, how capacity is judged and how special situations are handled are set out in this chapter's account of informed consent; here it is simply the ground needing no further justification once validly given.
- **Disclosure required by law.** Certain statutes compel a practitioner to disclose defined information, and where a law of the state requires the disclosure the duty of confidentiality gives way to it. The conduct code's own exception preserves exactly this, permitting a communication to be revealed where it is required by the laws of the state.
- **An order of a court or a competent authority.** A court or other authority empowered by law may direct the production of records or the giving of testimony, and confidentiality yields to a lawful order. The order defines and limits what must be produced; it is not a general waiver.
- **Protection of an identifiable other from serious harm.** Where withholding information would expose another person to a real risk to health or life, a proportionate disclosure to avert that risk is permitted. This is the ground the rest of the topic turns on.

MNEMONIC

Consent, Compulsion, Court, Caution

The principal grounds on which a confidence may lawfully be broken. **Consent** of the patient; **Compulsion** by a law of the state; a **Court** order or the direction of a competent authority; and **Caution** for an identifiable other in serious danger. A disclosure that fits no recognised ground has no footing and is a breach.

The last ground generates the hard cases and the examination questions, because it turns on judgement rather than on a document. It is available only when the danger is to an **identifiable other** and is serious, and even then it authorises only the disclosure necessary to avert the harm, made to the person who can act on it. It is a permission tightly bounded by proportionality, not a general waiver.

4.3 Tarasoff and the origin of the duty to warn

The vocabulary of a **duty to warn** entered clinical practice from a single American case. **Tarasoff**, decided by the California Supreme Court in **1976**, held that when a therapist determines, or under the standards of their profession should determine, that a patient presents a serious danger of violence to another, the therapist incurs an obligation to use reasonable care to protect the intended victim. The discharge of that obligation may require warning the intended victim, warning others likely to alert the victim, notifying the police, or taking whatever other steps are reasonably necessary in the circumstances. The confidentiality privilege yields to this duty: the protective purpose of the profession does not extend to guarding a patient's confidences at the cost of the intended victim's life.

The popular name understates the holding, and the discrimination is worth marking. The case did not create a narrow duty to send a warning; it created a broader **duty to protect**, of which warning is only one possible discharge. A therapist might protect the victim by warning them, by alerting someone able to warn them, by informing the police, or by intensifying treatment or arranging admission. Reducing the whole of it to a mechanical duty to warn shrinks a flexible standard of reasonable care into a single required act.

Two features of the case must travel with it into any Indian answer. First, it is United States common law, the decision of a state court, and it binds no Indian clinician; it is the origin of a concept, not a rule of practice here. Second, it frames a positive obligation, a duty the therapist incurs, which is a stronger thing than a permission to disclose, and it is on this second point that the Indian rule departs from it.

TRAP **Tarasoff is the United States origin of the duty to warn, not Indian law, and India permits protective disclosure without compelling it.** Candidates import Tarasoff wholesale and write that an Indian psychiatrist is under a legal duty to warn a third party. There is no such positive statutory duty in India. The Mental Healthcare Act's confidentiality section permits a proportionate disclosure to protect another; a permission is "may" and a duty is "shall", and the two are different laws. Answering with a duty where the statute gives only a permission loses the mark.

4.4 The Indian position: permission, not command

India has no case and no statute that imposes a Tarasoff-style positive duty to warn an endangered victim; what the law provides instead is a permission. That is a distinct question from the specific mandatory-reporting duties that particular statutes impose in defined situations, such as the reporting of child sexual abuse set out in the Child psychiatry: assessment, treatment, services and protection notes; those duties, where they apply, must be complied with on their own terms and are not displaced by anything said here. The Mental Healthcare Act's

confidentiality provision keeps confidentiality as the patient's right and the professional's duty, then lists the exceptions to it; among them is disclosure to protect any other person from harm or violence, releasing only the information necessary for that protection. The provision is permissive in character: it authorises the professional to make the protective disclosure and shields them when they do, but does not oblige them to make it. The full working of that section, its complete list of exceptions and the machinery around them, belongs to the Mental health legislation and forensic psychiatry notes and is named here rather than reworked; the point is the character of the provision, that it authorises and does not oblige.

The professional conduct code points the same way. Its confidentiality regulation allows a communication to be revealed where non-disclosure may itself be detrimental to the health of the patient or of another human being, again a permission to protect and not a duty to warn. Statute and code therefore converge on a single Indian rule: confidentiality yields to the protection of an identifiable other, but the yielding is discretionary and proportionate, exercised by a clinician who has judged the risk, not triggered automatically by the fact of a threat. A clinician who never discloses to protect an endangered third party may be criticised for poor judgement, but breaches no general duty to warn the victim, because Indian law imposes none; any separate mandatory-reporting duty a specific statute may create in a defined situation is a different matter and continues to apply on its own terms.

AXIS	TARASOFF (UNITED STATES)	MENTAL HEALTHCARE ACT CONFIDENTIALITY SECTION (INDIA)	MR X V HOSPITAL Z (INDIA)
SOURCE OF THE RULE	State supreme court, common law	Statute	Supreme Court judgment
LEGAL CHARACTER	A positive duty to protect	A permission to disclose	A holding that a protective disclosure was lawful
WHAT TRIGGERS IT	A serious danger of violence to another that the therapist determines or should determine	A need to protect any other person from harm or violence	A real risk to an identifiable person, a prospective spouse, from a life-threatening condition
EFFECT ON THE CLINICIAN	Must take reasonable steps to protect; the privilege yields	May disclose the information necessary to protect; the duty yields but is not compelled	The disclosure made was held not to breach confidentiality or privacy
WHAT IT DOES NOT DO	Does not fix one required act; warning is one option among several	Does not impose a duty to warn	Does not make privacy absolute, nor command disclosure in every case

4.5 Mr X v Hospital Z: the Indian judicial anchor

The Indian courts have addressed the limits of medical confidentiality directly, and the case every candidate should be able to name is **Mr X v Hospital Z**, decided in **1998**. A hospital disclosed a

patient's HIV-positive status to the woman he was about to marry. The court held that the disclosure violated neither the rule of confidentiality nor the patient's right to privacy, because the prospective spouse, an identifiable other, was thereby saved in time from a real risk to her health and life. The reasoning is the load-bearing part and repays exact memory: the right to privacy is not absolute and may be restricted to protect the rights, the health and the freedom of others.

Read carefully, the case supports the Indian permission and no more. It justified a disclosure that protected a specific person from a grave and avoidable harm; it did not announce a general duty on doctors to warn, nor make every disclosure lawful. Its principle is a limit on privacy, not an engine of disclosure: where a specific other faces a specific serious risk, protecting them is a legitimate reason to reveal what would otherwise be confidential. That is the same shape as the statutory permission and the protective ground in the general list.

IN INDIA

The Indian picture is coherent once its pieces are named: a statutory right to confidentiality with a protective exception in the Mental Healthcare Act, a professional conduct code that permits disclosure where silence would endanger the patient or another, and a Supreme Court holding that a protective disclosure to an identifiable person at real risk breaches neither confidentiality nor privacy. Nowhere in that picture is a positive duty to warn. The working rule for an Indian psychiatrist is therefore a permission exercised with judgement, not an American duty transplanted whole, and the difference between "may" and "shall" is what an answer must make explicit.

4.6 Making a protective disclosure well

Knowing that you may disclose is only the start; disclosing well is the harder part. Because the protective ground turns on judgement, the quality of the decision is what protects both the endangered third party and the clinician who acts. The organising idea is **proportionality**: the disclosure must be matched to the risk in its target, its content and its recipient, and no wider. The practical discipline runs as follows.

- Establish that the risk is to an identifiable person and is serious and real, not a vague unease that names no one.
- Prefer the least intrusive step that will actually avert the harm, whether intensifying treatment, arranging admission, or warning where a warning is what protects; escalation should track the danger.
- Disclose only the minimum necessary to the person able to act on it, not the whole clinical record and not to an audience wider than protection requires.
- Record the reasoning as it is made: the risk assessed, the options weighed, the ground relied on, and what was disclosed to whom. The contemporaneous note is what distinguishes a considered protective disclosure from a careless one.

GOOD TO REMEMBER

When a patient names a person they intend to harm, the move is neither silence nor a broadcast. Confirm that the threat is serious and the target identifiable, choose the least intrusive step that will actually protect them, disclose only what that step needs to whoever can act on it, and write down why. The defensible position is the proportionate one, and the record is what makes it defensible.

PITFALL

Treating a justified risk as a licence to empty the file. Once a clinician has decided that a protective disclosure is warranted, the temptation is to hand over the entire history to be safe, or to tell more people than need to know. The permission is to reveal what is necessary to avert the specific harm, to whoever can act on it, and no further; a disclosure wider than the risk requires is itself a breach, even where a narrower one would have been entirely lawful. Over-disclosure and non-disclosure are opposite failures of the same judgement.

4.7 The other direction of flow: the right to information

Confidentiality governs what leaves the consulting room about the patient, and it has a mirror-image companion governing what must reach the patient. The Mental Healthcare Act's section **22** gives a person with mental illness, together with their nominated representative, a right to information: about the provision under which they are admitted and its criteria, their right to seek review of that admission, and the nature of the illness and the proposed treatment plan with its known side effects, all in a language and form the person can understand. The complete machinery of this right, like that of the confidentiality right, belongs to the Mental health legislation and forensic psychiatry notes; it is named here to complete the picture.

The two rights are complementary rather than opposed. The patient is entitled to be told the truth about their own condition and care, and entitled to have what they disclose held in confidence. Confidentiality is not secrecy from the patient; it is the protection of the patient's information from the world outside the care they have entered, coupled with candour toward them within it.

Confidentiality is the default duty and disclosure the exception: it is lawful on a recognised ground, principally the patient's consent, a requirement of law, an order of a court or competent authority, or the protection of an identifiable other from serious harm, and even then only so far as the risk requires. Tarasoff is the United States origin of the duty to warn and does not bind Indian practice; in India the Mental Healthcare Act's confidentiality section permits, but does not command, a proportionate protective disclosure, and Mr X v Hospital Z holds that such a disclosure to an identifiable person at real risk is no breach.

5 · IPS code of ethics (Cuttack 1989)

A psychiatrist in India answers to two written standards of conduct at once, and they are not the same kind of thing. One is the profession's own **code of ethics**, drawn up by psychiatrists for

psychiatrists, which states the ideals the discipline holds itself to. The other is the statutory **professional-conduct code** made under the law that governs the medical register, which carries the disciplinary machinery and can end a career. The examiner who sets a question on the Indian Psychiatric Society code is really testing two things: whether the candidate knows the profession's own code and its history, and whether the candidate knows which statutory code is actually in force, because that second fact reversed itself recently and a great many textbooks now print the wrong answer.

This topic therefore has an unusually high yield relative to its size. The substance a candidate must carry is small and quotable, but it sits on a moving legal floor. The professional code is an ethical and professional standard; the statutory code is the enforceable one, and it has changed on paper without yet changing in force. Getting the currency right is the single discriminator between a safe answer and one that confidently states a regulation that does not operate. The underlying principles this code applies, the four principles of biomedical ethics, are set out in this chapter's account of the principles of medical ethics and are named here rather than relisted.

1989	2 Aug 2023	23 Aug 2023	2002
THE IPS CODE OF ETHICS APPROVED AT CUTTACK	THE 2023 REGULATIONS NOTIFIED	HELD IN ABEYANCE, DAYS LATER	THE MCI CODE THAT IS CURRENTLY OPERATIVE

5.1 Two codes, two kinds of force

The first discrimination to hold is between a professional code and a statutory code, because candidates blur them and the blur costs marks. A professional code of ethics is issued by a professional body to its own members; it articulates the standards the profession aspires to and expects, and it educates and guides more than it punishes. A statutory professional-conduct code is subordinate legislation made under the statute that regulates the medical profession; it defines misconduct and attaches consequences to it, and a breach can lead to erasure from the register. The two are not rivals. The professional code supplies the moral content and the statutory code supplies the enforceable floor, and in practice a serious breach of the profession's own ethics will usually also be a breach of the statutory conduct rules the regulator can act on.

For psychiatry the distinction has extra bite, because psychiatric practice raises ethical problems the general codes handle only thinly: consent where capacity is in question, confidentiality where a third party may be at risk, treatment that may be given against a patient's stated wishes. A discipline-specific code exists precisely to speak to these, which is why the Indian Psychiatric Society drew up its own rather than resting on the general medical code alone.

5.2 The Indian Psychiatric Society code and Cuttack, 1989

The Indian Psychiatric Society appointed a committee to prepare a code of ethics specifically for psychiatrists practising in India, and that code was approved at the Society's annual conference held in **Cuttack** in **1989**. This is the foundational Indian psychiatry-specific code of ethics, and its significance is as much symbolic as textual: it marked the point at which Indian psychiatry set down a written ethical standard of its own. For the examination the year and the place are the memorable pair, and they are the part most reliably asked.

The code is not a static document. What began at Cuttack has been revised and republished by the Society since, so the version a clinician reads today is the descendant of that original text rather than the original itself. The examinable spine is the lineage: a psychiatry-specific ethical code, originated by an IPS committee and adopted at Cuttack, which the profession has kept current. The content that follows is drawn from the Society's current published statement of that code.

IN INDIA

The IPS code sits alongside, not instead of, the statutory conduct rules that bind every registered medical practitioner. A psychiatrist is a doctor first, so the general professional-conduct code applies in full; the IPS code adds the discipline-specific ethical detail the general code cannot supply. Where the IPS code speaks of confidentiality, it is careful to tie the duty to the law of the land, which in Indian mental-health practice means the framework taught in the Mental health legislation and forensic psychiatry notes. The code guides the psychiatrist's conduct; the statute and the regulator supply the consequences.

5.3 What the code asks of the psychiatrist: the Fourteen Codes

The current published form of the code sets out the psychiatrist's duties as **fourteen** numbered codes. They do not need to be memorised verbatim, but a candidate should be able to reproduce their shape, because they map neatly onto the principles this chapter teaches elsewhere and onto the consent and confidentiality duties taught in their own fragments here. The core duties the code lays down are these:

- **The patient comes first.** The patient's care, well-being and best interests are the paramount consideration for the psychiatrist, which is the code's governing clause and the one everything else serves.
- **Competent, dignified care.** The psychiatrist provides competent care while respecting the humanity, dignity and autonomy of the person, so that skill and respect are held together rather than traded off.
- **Valid informed consent.** The psychiatrist acts to establish valid, informed consent with people living with mental illness; the elements of that consent and its special situations are taught in this chapter's account of informed consent in psychiatry and are not reworked here.
- **Professionalism and conflicts of interest.** The psychiatrist maintains professional standards, which includes recognising and managing conflicts of interest rather than pretending they do not arise.
- **Confidentiality within the law.** The psychiatrist upholds the patient's right to confidentiality, but expressly within the provisions the law of the land prescribes; the default duty and its permitted exceptions belong to this chapter's account of confidentiality and its limits.
- **Ethical research.** Research is conducted ethically and under the oversight of ethics committees or institutional review boards, a duty this chapter's account of the ethics of research develops in full.

- **No exploitation of the relationship.** The psychiatrist upholds the sanctity of the doctor-patient relationship and does not exploit it for personal, social, business or sexual gain, which is the code's firmest prohibition and the seam it shares with the topic of boundary violations.

Read together, the codes are less a checklist than a description of a trustworthy psychiatrist: one whose skill is placed at the patient's service, who seeks genuine agreement, who guards what is told in confidence, and who never turns the relationship to private advantage. That last duty, against **exploitation** of the relationship, is the one the code states most absolutely, and it is worth carrying as the code's moral centre.

5.4 The statutory code and the currency trap: 2002 operative, 2023 in abeyance

Here is the fact that decides the mark. The professional-conduct code currently operative for Indian doctors is the Indian Medical Council (Professional Conduct, Etiquette and Ethics) Regulations, 2002, commonly abbreviated the MCI 2002 code after the Council that made it. It is tempting to assume the newer instrument has replaced it, and the newer instrument does exist: the National Medical Commission Registered Medical Practitioner (Professional Conduct) Regulations, 2023 were notified by the Commission on 2 August 2023 and were to come into force from the date of their publication in the Official Gazette. On the face of the notification, the 2023 Regulations looked like the new code.

They did not survive the month. On 23 August 2023 the Commission held the 2023 Regulations in **abeyance** with immediate effect, clarifying that they would not be operative or effective until a further Gazette notification, and in the same instrument it re-adopted and made effective the Indian Medical Council 2002 Regulations. The net position is precise and counter-intuitive: the 2023 code is notified but suspended, and the 2002 code is the one that governs conduct today. A candidate who writes that the NMC 2023 Regulations are the current professional-conduct code is stating a regulation that does not operate.

RULE **The operative statutory professional-conduct code is the MCI 2002 Regulations; the NMC RMP 2023 Regulations are notified but held in abeyance and are not in force.** The 2023 Regulations were notified and were to commence on Gazette publication, but the Commission suspended them within weeks and re-adopted the 2002 Regulations with immediate effect. Until a further Gazette notification revives the 2023 code, conduct is judged against the 2002 code. State the 2002 code as live and the 2023 code as notified-but-in-abeyance; do not present the 2023 Regulations as the current law.

TRAP **Naming the NMC 2023 Regulations as the code in force.** Because the 2023 Regulations were formally notified and are widely reported as the new ethics code, candidates and even recent textbooks cite them as operative. They are not: they were held in abeyance days after notification and remain suspended pending a further Gazette notification, while the 2002 MCI Regulations were re-adopted and are the code actually applied. The examinable point is not the content of either code but the currency: the newer, notified instrument is dormant and the older one governs.

5.5 Professional misconduct and graded discipline

Even though it does not currently operate, the suspended 2023 code repays study as a proposed framework, though its future operative form is uncertain: a further Gazette notification could revive, amend or replace it. Its treatment of misconduct is exam-friendly. In that code, professional misconduct is defined broadly at Regulation **37**: any violation of the Regulations, or of other applicable Acts relating to medical practice in force, shall constitute professional misconduct. The definition is deliberately open-ended, so that conduct need not be separately itemised to be actionable; a breach of the conduct rules is itself the misconduct.

The consequences are graded rather than binary. The 2023 code arranges disciplinary action across **five** levels, running from exoneration through a reformative warning and fixed periods of suspension of increasing length up to permanent debarment from practice. This graduated structure matters clinically: the regulator's response is meant to be proportionate to the gravity of the breach, so a first, minor lapse and a serious, repeated one do not attract the same sanction. A separate provision addresses criminal conviction: where a practitioner is convicted of a cognizable offence involving **moral turpitude**, that conviction may result in suspension of the licence to practise.

> **PITFALL**
>
> Reading conviction as automatic erasure. The provision on a cognizable offence involving moral turpitude says such a conviction may result in suspension, not that it must; the sanction is discretionary and sits within the graded scheme, not outside it. Telling a colleague that any conviction ends the registration overstates the rule and misreads the modal verb. A conviction opens the disciplinary process and permits suspension; it does not, of itself, strike the name off.

5.6 How the two codes bind together

The profession's code and the statute's code are two faces of one duty. The IPS code tells the psychiatrist what good practice looks like; the statutory conduct code is the instrument through which failures of that practice are called to account. A psychiatrist who exploits the therapeutic relationship, for instance, breaches the IPS code's firmest prohibition and, at the same time, commits professional misconduct the regulator can act on. The moral standard and the enforceable standard converge on the same conduct from different directions, which is why a candidate should be able to move between them: cite the IPS code for the ethical content and the statutory code for the consequence.

AXIS	IPS CODE OF ETHICS (CUTTACK LINEAGE)	STATUTORY PROFESSIONAL-CONDUCT CODE
WHO ISSUES IT	The Indian Psychiatric Society, for psychiatrists	The statutory medical regulator, for all registered practitioners
NATURE	Professional and aspirational; discipline-specific	Subordinate legislation; enforceable
PRIMARY FUNCTION	Guides and educates on ethical practice	Defines misconduct and attaches sanctions
CURRENCY	Originated at Cuttack, kept current by the Society	MCI 2002 Regulations operative; NMC 2023 Regulations in abeyance
CONSEQUENCE OF BREACH	Professional and reputational; feeds the statutory process	Graded action up to erasure from the register

GOOD TO REMEMBER

When a conduct question arises in real practice, ask two questions in order. First, what does good psychiatric ethics require here, for which the IPS code and the four principles are the guide. Second, which enforceable rule is engaged, and against which code, for which the answer today is the MCI 2002 Regulations and not the suspended 2023 code. Keeping the aspirational and the enforceable separate stops a clinician from either dismissing the profession's own code as toothless or mistaking the dormant statute for the live one.

The Indian Psychiatric Society's psychiatry-specific code of ethics was approved at Cuttack in 1989 and, in its current published form, states the psychiatrist's duties as fourteen codes centred on the patient's paramount interest, valid consent, confidentiality within the law and no exploitation of the relationship; the operative statutory conduct code is the MCI 2002 Regulations, while the NMC RMP 2023 Regulations, though notified, are held in abeyance and are not in force.

6 · Professional negligence and medical malpractice (four Ds, vicarious liability)

Every clinical act carries the standing risk that a bad outcome will be read as a wrong done. A patient who is harmed in the course of care may frame that harm as the doctor's fault, and the law of negligence is the machinery that decides whether the framing is right. For the psychiatrist the stakes are peculiar, because so much of the work is judgement exercised under uncertainty, with outcomes that are probabilistic and diagnoses that are contested; the discipline of this topic is learning exactly what turns an adverse outcome into an actionable wrong, and what does not. The examiner is testing whether a candidate can separate the two.

The account here is built around four questions that a negligence claim must answer in turn: was a duty owed, was it breached, did the breach cause harm, and was there harm to be caused. Those four questions are the "four Ds" that every candidate can recite, but the more precise formulation is what the Supreme Court of India actually said, and the discrimination between the mnemonic

and the holding is where marks are made and lost. On the standard against which a breach is judged, on the higher bar the criminal law sets, and on the liability an employer carries for its staff, the rules are settled and quotable. The forum in which a patient brings such a claim, chiefly the consumer forum, belongs to this chapter's account of the Consumer Protection Act and medical practice, and is named here rather than reworked.

1957	1997	1996	2005
BOLAM, THE ORIGIN OF THE PROFESSIONAL STANDARD OF CARE	BOLITHO, THE LOGICAL-BASIS GLOSS ON BOLAM	ACHUTRAO, THE INDIAN AUTHORITY ON HOSPITAL LIABILITY	JACOB MATHEW, THE INDIAN SETTLEMENT OF MEDICAL NEGLIGENCE

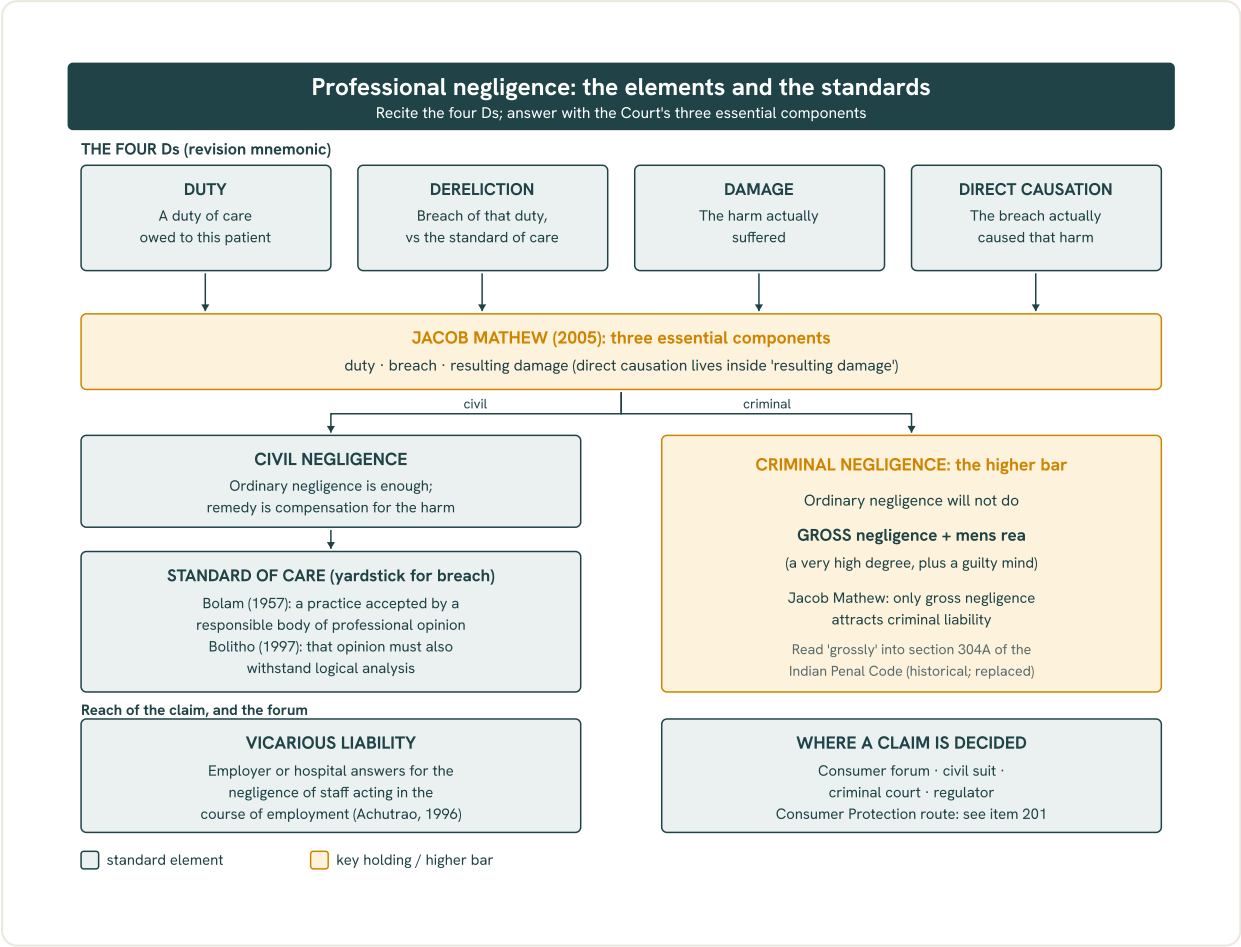

Fig 26.5. Professional negligence: the four Ds unpack the three essential components of Jacob Mathew (2005), breach is judged by Bolam as qualified by Bolitho, and criminal liability needs gross negligence plus mens rea.

6.1 What actionable negligence is: the four Ds and the three components

In ordinary language **negligence** is carelessness, but as a cause of action it is a structured thing with parts that must all be present. It is the breach of a duty caused by an omission to do what a reasonable person, guided by the considerations that ordinarily regulate human affairs, would do, or the doing of what a prudent and reasonable person would not do. A patient who alleges it must establish each of its elements; the absence of any one defeats the claim entirely, however grievous the outcome.

The revision mnemonic gathers those elements as the four Ds: a **Duty** of care owed to the patient, a **Dereliction** or breach of that duty, resulting **Damage**, and **Direct causation** linking the breach to the damage. The mnemonic is a useful scaffold and worth keeping, but it must be

married to what the Court actually held. In **Jacob Mathew** the Supreme Court of India stated that the essential components of negligence are **three**: duty, breach and resulting damage. Causation is not dropped; it lives inside "resulting damage", because damage that does not result from the breach is not the defendant's damage at all. The four Ds and the three components describe the same law: the mnemonic simply unfolds the causation that the holding keeps folded into its third element.

MNEMONIC

Duty, Dereliction, Damage, Direct causation

The four Ds of the negligence action: a **Duty** of care owed to this patient; a **Dereliction**, the breach of that duty measured against the standard of care; the **Damage** actually suffered; and the **Direct causation** that ties the breach to the harm. Recite the four for structure, but answer with the Court's three components, causation embedded in resulting damage, when asked for the authority.

TRAP **The Supreme Court states three essential components, not four Ds.** Candidates write that the Court laid down "four Ds" and lose the mark for putting a teaching mnemonic in the Court's mouth. The holding in Jacob Mathew names three components, duty, breach and resulting damage, with causation carried inside the third. State the three as the law, then offer the four Ds as the device that unpacks the causation requirement. Getting the direction of that relationship right, mnemonic derived from holding and not the reverse, is what a careful answer shows.

6.2 The standard of care: the Bolam test

The second element, breach, cannot be judged without a yardstick, and the yardstick is the heart of medical negligence law. A doctor is not measured against the ordinary reasonable person, because the ordinary person does not possess the special skill in question. This is the insight of the **standard of care** for skilled work, given its classical statement in **Bolam**. Where an act involves a special skill or competence, negligence is judged by the standard of the ordinary skilled person exercising and professing to have that skill, not by the standard of the ordinary person on the street. The practitioner need not possess the highest expert skill; it is enough that they exercise the ordinary skill of an ordinarily competent practitioner of that art.

The operative principle follows: a practitioner is not negligent if they have acted in accordance with a practice accepted as proper by a responsible body of professional opinion, even if other practitioners would have taken a different view. Medicine tolerates genuine differences of approach, and the law protects the doctor who has followed one recognised school of thought against the charge that a different school would have done otherwise. This is why a mere error of judgement, or the existence of a better alternative in hindsight, is not by itself negligence.

IN INDIA

The Bolam standard is not merely borrowed here; the Supreme Court in Jacob Mathew adopted it expressly, holding that the test for determining medical negligence laid down in Bolam holds good in its applicability in India. The practical consequence for civil liability is precise: so long as a doctor follows a practice acceptable to the medical profession of the day, they are not negligent merely because a better alternative existed, or because a more skilled doctor might have chosen differently. The Indian civil standard is therefore the accepted-practice standard, applied to Indian conditions and the resources actually available, not a counsel of perfection.

6.3 Bolam qualified: the Bolitho gloss

Bolam left an obvious gap. If any body of professional opinion could shelter a defendant, then a defendant needed only to find one supportive expert, and the profession, rather than the court, would decide what counted as reasonable care. The correction came in **Bolitho**, which glosses rather than overturns Bolam. A body of professional opinion protects a defendant only if that opinion can be shown to rest on a logical basis. The adjectives the law uses, that the body of opinion be responsible, reasonable and respectable, require the court to be satisfied that its exponents have actually weighed the comparative risks and benefits and reached a defensible conclusion. In the rare case where the opinion relied on is not capable of withstanding logical analysis, the judge is entitled to hold that it is not reasonable or responsible, and the shelter falls away.

The combined rule, Bolam as qualified by Bolitho, is the single most examinable proposition in this topic. The standard of care is set by a responsible body of professional opinion, but the court retains a residual power to reject that opinion when it cannot survive logical scrutiny. This keeps the final judgement of reasonableness with the court while giving proper weight to genuine professional practice, and it forecloses the defence built on an opinion that is merely asserted rather than reasoned.

RULE **The standard of care is Bolam as qualified by Bolitho: a responsible body of professional opinion sets the standard, but only where that opinion withstands logical analysis.** A doctor who acts in line with an accepted professional practice is not negligent, and this protects legitimate differences of clinical approach. Bolitho adds the safety catch: the practice relied on must have a logical basis, weighing risks against benefits, or the court may find it neither reasonable nor responsible. Both halves must appear in a full answer, because Bolam alone overstates the doctor's protection and misses where Indian and English law now stand.

GOOD TO REMEMBER

What protects the clinician is not a good outcome, which cannot be guaranteed, but a defensible process. Choose a management that a responsible body of your profession would accept, be able to say why the comparative risks and benefits pointed that way, and write that reasoning in the notes as it is made. A documented choice within accepted practice is answerable to Bolam and Bolitho even when the result is poor; an undocumented departure from it is exposed even when the result is good.

6.4 Causation: the fourth D and where the burden lies

Even a proven breach of duty does not by itself make a case, and this is the element candidates most often skate over. **Causation** is the requirement that the breach actually produced the injury complained of, and it is a distinct hurdle the claimant must clear. Bolitho is authority for the point as well as for the standard of care: where a breach of the duty of care is proved or even admitted, the burden still lies on the plaintiff to prove that the breach caused the injury suffered. A patient who was negligently managed but who would have come to the same harm regardless has suffered a breach without a remedy, because the breach caused nothing.

This is the "direct causation" the fourth D names, and it is why the mnemonic is a fair unpacking of the three components rather than an inflation of them. The link between breach and damage must be shown, not assumed from the coincidence of a lapse and a bad result. For the psychiatrist, where outcomes are multiply determined and the natural course of an illness may itself account for the harm, the causation question is frequently the strongest ground of defence: the illness, not the treatment, may be the operative cause.

6.5 Civil and criminal negligence: the higher bar

The same careless act can be met with a civil claim for compensation or, in a serious case, a criminal prosecution, and the two run on entirely different standards. The distinction is grounded and load-bearing. For civil liability the accepted-practice standard of Bolam and Bolitho governs, and ordinary negligence suffices. For criminal liability the bar is far higher: **mens rea** must be shown, and the degree of negligence must be **gross negligence**, or negligence of a very high degree. Negligence that is neither gross nor of a high degree may found a civil action but cannot form the basis of a prosecution. In Jacob Mathew the Court read the words "rash or negligent act" in the historical penal provision, Section **304A** of the Indian Penal Code, as qualified by "grossly", so that only gross negligence would attract criminal liability.

The rationale is protective. A doctor who acts in good faith and within accepted practice should not face the criminal law every time treatment fails, because that would make defensive medicine the rule and deter the very risk-taking that patients need. The criminal law is reserved for negligence so gross that it approaches recklessness, coupled with the guilty mind the offence requires. The insanity-defence doctrine and the burden of proof that attend criminal responsibility more generally belong to the Mental health legislation and forensic psychiatry notes and are not reworked here; the point retained is the standard specific to negligence.

AXIS	CIVIL MEDICAL NEGLIGENCE	CRIMINAL MEDICAL NEGLIGENCE
STANDARD APPLIED	Bolam, as qualified by Bolitho: departure from accepted responsible practice	Gross negligence, or negligence of a very high degree
MENTAL ELEMENT	None required; the act and its consequences are judged objectively	Mens rea must be shown to exist
DEGREE OF FAULT	Ordinary negligence is enough	Ordinary negligence will not do; the lapse must be gross
WHAT THE CLAIMANT SEEKS	Compensation for the damage caused	Punishment of the practitioner by the State
PURPOSE OF THE STANDARD	To make good the harm to the patient	To protect the good-faith doctor from prosecution for every failure

PITFALL

Citing the Indian Penal Code as the current source of the criminal-negligence provision. Jacob Mathew construed Section 304A of the Indian Penal Code, which was the operative penal code when the case was decided, but the substantive criminal law has since been replaced and the old codes are now historical. Quoting the Court on the qualifying word "grossly" is correct; presenting the Indian Penal Code as the code in force today is not. The current penal framework and the savings rule that decides which code applies to a given prosecution are set out in this chapter's account of the penal-code framework and its transition; name the new provision as current and the old as historical.

6.6 Vicarious liability: the employer answers for the servant

A negligence claim does not stop at the individual who erred. **Vicarious liability** is the principle that an employer, though personally without fault, is answerable for the harm done by the fault or negligence of a servant acting in the course of employment. The doctrine matters intensely in practice, because the individual clinician may be uninsured or of modest means while the hospital that employs them is not, and because the harm done by any of the doctors or other employees through whom a hospital delivers care is answered for by the hospital itself. The rule is stated authoritatively in **Achutrao**: an employer, though guilty of no fault himself, is liable for the damage done by the fault or negligence of his servant acting in the course of his employment.

The liability is not unlimited, and its boundaries are where the marks sit. Applied to the hospital, the Court held that running a hospital is a welfare activity and not a sovereign function, so the State or the hospital cannot claim sovereign immunity and is vicariously liable for the negligence of its doctors and other employees. The claimant may sue the individual, the institution, or both. The requirements that must hold, and the defence that fails, are these:

- **An employer-servant relationship.** The person who erred must be an employee, not an independent contractor beyond the employer's control; the closer the control over how the work is done, the firmer the liability.

- **Acting in the course of employment.** The negligent act must be part of, or reasonably incidental to, the work the servant is engaged to perform, not a personal venture unconnected with it.
- **A welfare, not a sovereign, function.** Because running a hospital is a welfare activity, the defence of sovereign immunity does not shield a public hospital from vicarious liability for its staff.

6.7 Where a negligence claim is decided

A patient harmed by alleged negligence is not confined to a single door, and the available tracks run on different standards and to different ends:

- **The consumer forum.** A dedicated statutory route treats a deficiency in a medical service as consumer redress; that forum, its remedy and the settled position that paid medical services fall within it belong to this chapter's account of the Consumer Protection Act and medical practice, and are named here without being reworked.
- **An ordinary civil suit.** A patient may sue for damages in the courts, where ordinary negligence against the accepted-practice standard suffices.
- **A criminal prosecution.** Available only where the negligence is gross and accompanied by the guilty mind the offence requires.
- **A complaint to the regulator.** Engaging the professional-conduct code, this track is concerned with fitness to practise rather than with compensation.

The tracks are independent and may run in parallel: a single episode of negligent care can generate a consumer complaint, a civil suit, a criminal case and a disciplinary inquiry at once, each on its own standard and to its own end. What travels across the civil and consumer forums is the substance taught in this fragment, the elements of the action and the standard of care: each asks whether a duty was breached against the Bolam-Bolitho yardstick and whether the breach caused the harm. The criminal court demands more, gross negligence and mens rea, and the regulator asks about fitness to practise rather than compensation, so the yardstick is not identical everywhere. The forum changes the procedure, the degree of fault required and the remedy; the underlying account of what negligent care is remains the reference point each forum starts from.

Actionable negligence has three essential components in Jacob Mathew, duty, breach and resulting damage, with causation embedded in the third and unpacked by the four-D mnemonic; the standard for breach is Bolam as qualified by Bolitho, an accepted responsible practice that must also withstand logical analysis; civil liability needs ordinary negligence while criminal liability needs gross negligence plus mens rea; and by vicarious liability the hospital, running a welfare and not a sovereign function, answers for the negligence of its servants acting in the course of employment.

7 · Consumer Protection Act and medical practice

A doctor who charges for care has, in the eye of the law, supplied a service, and a patient who feels short-changed by that service can come after the doctor not only as an injured plaintiff but as a dissatisfied consumer. That single move, treating the clinical encounter as a transaction in services, is what brought medical practice within consumer law and gave the aggrieved patient a forum that is faster and cheaper than an ordinary civil suit. The marks are for knowing which statute is actually in force, what the Act means by "service" and by "deficiency", and how the landmark judgment settled that a doctor's work is a service the Act can reach: each a discrete, quotable point, and each a place a hurried candidate goes wrong.

This fragment owns the consumer forum and its definitions, not the law of negligence itself. Whether a doctor was negligent, the elements of the action and the standard of care against which a breach is measured, belongs to this chapter's account of professional negligence and medical malpractice and is named here, not reworked. The Consumer Protection Act does not invent a new standard of care; it opens a door to a particular tribunal and calls the wrong a "deficiency in service". Keeping that boundary clear, forum here, standard there, is the discipline the examiner is testing.

2019	1986	1995
THE CONSUMER PROTECTION ACT NOW IN FORCE	THE EARLIER ACT, SINCE REPEALED	IMA V V.P. SHANTHA BROUGHT MEDICINE WITHIN THE ACT

7.1 The current statute and what it replaced

The first thing to fix is currency, because the obvious answer is now the wrong one. The operative law is the Consumer Protection Act, 2019, enacted as Act 35 of 2019, which received assent on 9 August 2019. By Section **107(1)** it repealed the earlier Consumer Protection Act, 1986. The older Act is historical, and a candidate who cites it as governing law is quoting a repealed statute.

The Act's commencement is itself a conditional worth stating precisely, because it is not a single switch. It comes into force on such date or dates as the Central Government appoints by notification, and different dates may be appointed for different provisions of the Act and for different States. That staggered commencement means the practical answer to "when did it apply" is a matter of notification rather than of the date of assent. What matters for medical practice is that the core concepts, service, deficiency and consumer, are carried forward from the old Act with their sense intact.

7.2 What the Act means by "service"

Everything turns first on whether the doctor supplies a **service** the Act recognises, because only then can the patient be a consumer of it. Section **2(42)** defines service expansively as service of any description made available to potential users, with an illustrative sweep from banking and insurance through transport and housing construction. The breadth is deliberate: the definition is inclusive, not a closed list, so a service is not excluded merely because it is unnamed.

Against that breadth the section sets two express exclusions, and stating the definition without them is how a candidate loses the mark:

- **Service rendered free of charge.** A service rendered free of charge is outside the definition, a carve-out decisive for camps, charitable care and government facilities; but as the discussion of free versus paid care below shows, whether care is "free" is read by how the facility is funded, not by what a given patient paid.
- **Service under a contract of personal service.** A master-and-servant employment relationship is excluded, so that the ordinary grievance of an employee against an employer does not become a consumer complaint.

The free-of-charge limb generates almost all the medical litigation, because it forces the question of exactly when treatment counts as free.

7.3 What the Act means by "deficiency"

If the encounter is a service, the actionable wrong is a **deficiency** in it. Section **2(11)** defines deficiency as any fault, imperfection, shortcoming or inadequacy in the quality, nature and manner of performance that is required to be maintained by law or has been undertaken by contract in relation to a service. Critically for medicine, the definition expressly includes any act of negligence, or omission or commission, by the provider that causes loss or injury to the consumer. This is the bridge that lets a negligence complaint be pursued as a consumer matter at all.

What the Act does not do is tell you when negligence exists. The **deficiency in service** is defined by reference to the performance "required to be maintained by law", and the content of that requirement, the four-part structure of the negligence action and the standard of care by which a breach is judged, is drawn from the general law set out in this chapter's account of professional negligence and medical malpractice. The consumer forum applies that standard; it does not lower it. A poor outcome is not a deficiency unless the care fell below the standard the law already demands, which is why the same fact may be a deficiency in one case and a non-negligent misadventure in another.

7.4 The landmark: medicine is a "service"

For years it was argued that a learned profession stood apart from consumer law, and that a doctor answerable to the medical regulator could not also be hauled before a consumer tribunal. That argument was settled by **IMA v V.P. Shantha**, which remains the governing precedent. The Court held that service rendered to a patient by a medical practitioner, by way of consultation, diagnosis and treatment, both medicinal and surgical, falls within the expression "service" as then defined in Section **2(1)(o)** of the 1986 Act, the historical predecessor of the current definition. Two exceptions were carried over from the statute itself: service rendered free of charge to every patient, and service under a contract of personal service.

The judgment also disposed of the profession's favourite escape route. The fact that a doctor is subject to the disciplinary control of the Medical Council does not take the doctor's service outside the Act. Regulatory oversight and consumer liability are parallel, not alternative; a clinician can face both a disciplinary inquiry into fitness to practise and a consumer complaint for compensation arising from the same episode. That the Court read a professional's work as a

marketed service, rather than as a calling immune from commercial law, is the conceptual core of the whole topic.

RULE **A doctor's diagnostic and therapeutic service is "service" under the Act, and a deficiency in it is actionable in the consumer forum, unless the service is rendered free of charge to everybody or under a contract of personal service.** The default is coverage; the exclusion is narrow and must be stated with its condition. Where a practitioner or facility charges no fee from any patient, the service is outside the Act, and the payment of a token amount for registration only does not change that position. The rule is not "free treatment is never covered" but "treatment free to everyone is not covered", and the difference between those two sentences is where the marks live.

7.5 The free-versus-paid distinction

The single most examined product of Shantha is the way it worked the free-of-charge exclusion out across the mixed economy of Indian hospitals, where paying and non-paying patients are treated side by side. Rather than a crude "did this patient pay" test, it asks how the facility is funded, so that a patient treated free at a hospital that charges others is still a **consumer**. The accompanying grid sets out the four situations the Court distinguished.

SITUATION	IS IT "SERVICE" UNDER THE ACT?	IS THE RECIPIENT A "CONSUMER"?
CHARGES ARE PAYABLE AND THE PATIENT PAYS	Yes; paid medical service falls squarely within the Act	Yes; may complain of a deficiency
CROSS-SUBSIDISED: THOSE WHO CAN PAY ARE CHARGED, THOSE WHO CANNOT ARE TREATED FREE	Yes; even the free treatment is "service"	Yes; the non-paying patient is also a consumer
FREE TO EVERYBODY, NO CHARGE TAKEN FROM ANY PATIENT	No; wholly free service is outside the Act	No
ONLY A TOKEN REGISTRATION FEE IS TAKEN, ALL ARE TREATED FREE	No; the token fee does not alter the free character	No

The organising idea is that the paying patients underwrite the free ones, so the institution supplies a service for consideration and the benefit of that service reaches the non-paying patient too. Coverage follows the economic character of the facility, not the receipt in a given patient's hand, and only where the service is free to all comers does the exclusion truly bite.

TRAP **Reading the free-of-charge exclusion too widely, so that any free treatment is treated as outside the Act.** Candidates state the exclusion correctly, then apply it as though a patient who paid nothing can never complain. Shantha holds the opposite for the cross-subsidised case: where a hospital charges paying patients and treats others free, the free treatment is still "service" and its recipient a consumer. The exclusion is confined to the facility that charges no one at all. Answer with the four situations, not with the headline, because the headline states a rule the judgment expressly rejected.

7.6 The forum, the remedy and the boundary with negligence

What the Act really gives the patient is a place to go. Beyond defining service and deficiency, it establishes a dedicated tier of consumer commissions, sitting at the district, State and national

levels, before which a consumer may bring a complaint of deficiency and seek redress, most commonly an award of compensation. The attraction over an ordinary civil suit is procedural: the consumer route offers a dedicated statutory forum and a compensation remedy, and it became a common route for medical grievances once Shantha confirmed doctors were within reach of it. The exact pecuniary jurisdiction of each tier, the limitation period for a complaint, and the statutory definitions of "consumer" and "complaint" are matters of the Act's machinery not reproduced here.

The boundary with the law of negligence is the point to carry away. The commission decides the forum question, is this a service, is the complainant a consumer, has there been a deficiency, but the deficiency question still turns on the ordinary negligence standard, the accepted-practice test qualified by the requirement of a logical basis, taught in this chapter's account of professional negligence and medical malpractice. The Consumer Protection Act is thus best understood as a remedy and a forum bolted onto the substantive law of negligence, not as a separate or stricter code of medical liability. A clinician who satisfies the standard of care has committed no clinical negligence, though the statutory definition reaches wider than negligence alone: a fault, imperfection, shortcoming or inadequacy in a performance the law requires or a contract undertook can still be a deficiency.

IN INDIA

Since IMA v V.P. Shantha the consumer commission has been the workhorse of medical-liability litigation in India, because it spares the patient the cost and delay of a regular civil action. For the practising psychiatrist the Act bites at the ordinary paid consultation: consultation, diagnosis and treatment given for a fee is service within the Act, so a dissatisfied patient may bring a complaint alleging a deficiency in it. The fee-paying private consultation is the paradigm covered service, so the everyday out-patient encounter falls squarely within the Act's reach.

GOOD TO REMEMBER

Do not treat a fee waiver as a shield. If your clinic charges other patients, the concession you extend to one does not put that patient's care outside the Act; a camp or charitable service is exempt only when nobody is charged at all. Because coverage follows how the service is funded rather than what this patient paid, hold every episode of care, subsidised, discounted or free within a paying practice, to the same documented standard, so that the deficiency question is answered by your notes whichever forum asks it.

PITFALL

Citing the Consumer Protection Act, 1986 as the statute in force. It was repealed by the 2019 Act, and quoting the old Act, or its old section for the definition of service, in a report, an opinion or an examination answer marks the writer as working from a superseded source. The case law decided under the 1986 Act, IMA v V.P. Shantha among it, remains good authority on the concepts, but the section it construed is historical. Name the 2019 Act as current and treat the 1986 provisions as the predecessor they now are.

The operative statute is the Consumer Protection Act, 2019, which repealed the 1986 Act; a doctor's paid diagnostic and therapeutic work is "service" and its negligent shortcoming a "deficiency", so IMA v V.P. Shantha lets a patient sue as a consumer, with only service that is free to everybody, unaltered by a token registration fee, falling outside the Act, while the standard of negligence itself is drawn from the account of professional negligence.

8 · Expert testimony and the psychiatrist as expert witness

Why the marks are here. Forensic work asks the psychiatrist to do something the rest of medicine never demands: to serve a master other than the patient. The clinician who, in the consulting room, owes undivided loyalty to the person in front of them may later be asked by a court to examine a litigant, an accused or a claimant and to report - not for that person's benefit, but for the administration of justice. The two examinations can look almost identical across the desk, yet they pull the clinician in different directions: to whom the duty is owed, and what confidentiality and stance the encounter carries, invert between them, even though duties of honesty, respect and competence hold in both. Evaluators who miss this produce reports that are partisan, poorly received, or quietly damaging to the very patient they meant to help; candidates who miss it lose an easy viva question that examiners return to year after year.

This section teaches the psychiatrist as an **expert witness**: how the treating role is held apart from the expert role, and how the law separates the opinion the expert is uniquely permitted to give from the facts to which an ordinary witness is confined. The rules of admissibility, the court hierarchy and the mechanics of how an opinion is received in evidence are set out elsewhere in this chapter and are only named here; the criteria of criminal responsibility and of fitness to stand trial belong to the Mental health legislation and forensic psychiatry notes.

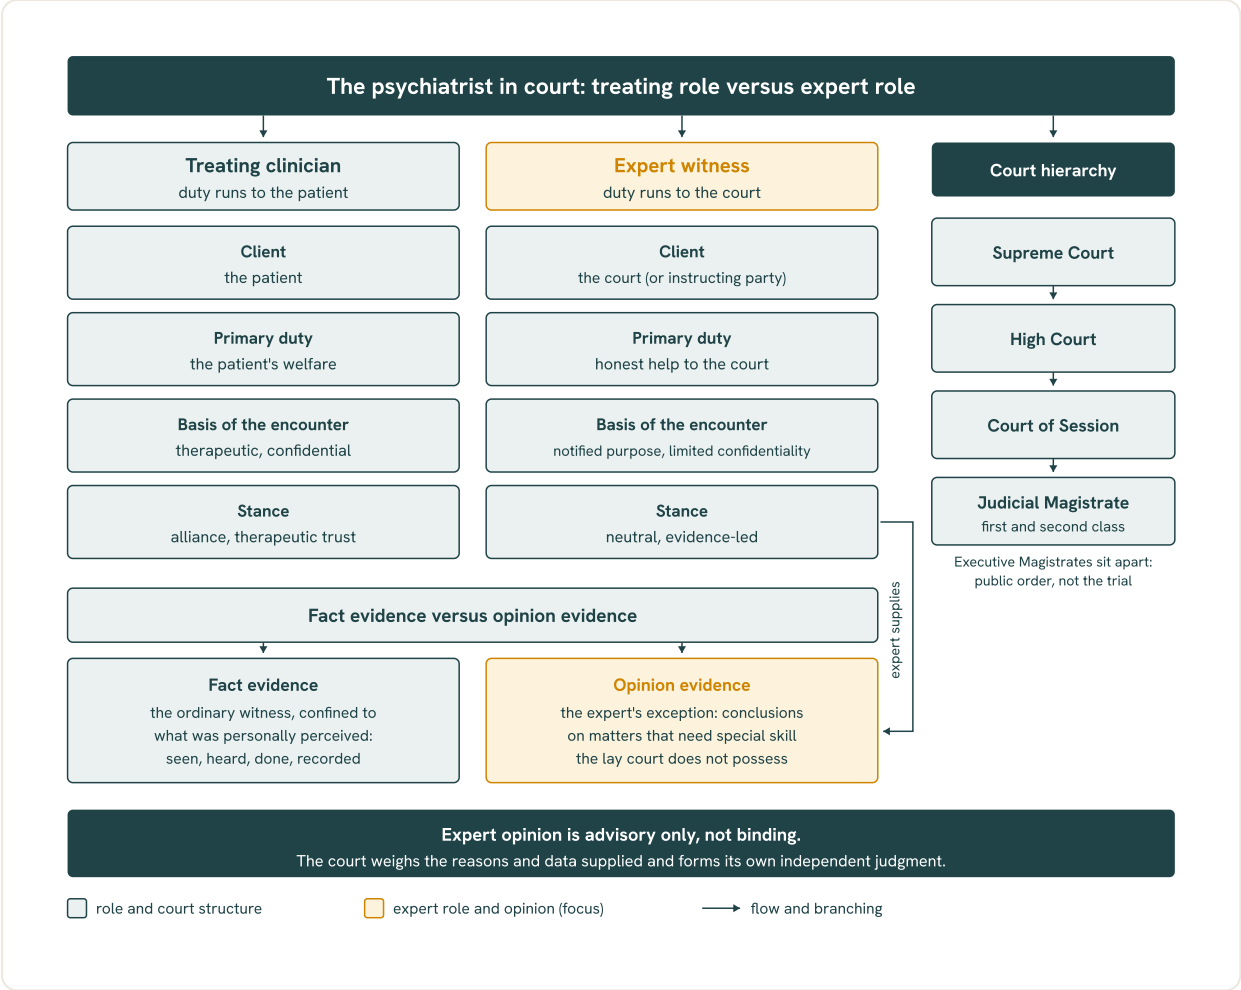

Fig 26.6. The treating role serves the patient and the expert role serves the court; the ordinary witness gives fact while the expert alone gives opinion on matters needing special skill, and that opinion is advisory only, the court never bound by it (Ramesh Chandra Agrawal, 2009).

8.1 Two roles, one clinician: treatment and evaluation

The confusion at the heart of forensic psychiatry is that one professional, with one set of skills, is asked to occupy two structurally different positions. In the **treating role** the client is the patient. The primary obligation is to that patient's welfare, resting on the principles of beneficence and non-maleficence (the four principles of biomedical ethics are set out elsewhere in this chapter and named here only). Consent is therapeutic consent to be helped; confidentiality is the default posture, breached only within the narrow permitted circumstances taught elsewhere in this chapter. The stance is one of alliance and therapeutic trust, because trust is itself part of the treatment, while clinical assessment stays objective.

In the **forensic evaluator** role almost every one of those settings inverts. The functional client is the court, or a retaining party whose instructions the evaluator accepts but whose interests do not command the opinion. There is no therapeutic purpose, and confidentiality is correspondingly limited rather than absent: before anything is said, the person examined must be told that the encounter is not treatment, that what they disclose is not held in the usual clinical confidence and may be set out in a report, and who will receive that report. The goal is not the person's welfare but an accurate answer to a legal question, and the stance is neutral and, where the data demand it, sceptical. When these two roles are forced into one person at one time - the treating

psychiatrist asked to be the court's expert on their own patient - a dual relationship forms that corrodes both the objectivity the court needs and the alliance the patient needs.

AXIS	TREATING ROLE	EXPERT ROLE
Who is the client	The patient	The court (or an instructing party)
Primary duty	The patient's welfare	Honest assistance to the court
Basis of the encounter	Therapeutic consent	Notified purpose, limited confidentiality
Confidentiality	Default, narrowly limited	Limited by the forensic purpose
Goal of the contact	To help the person	To answer a legal question accurately
Stance toward the person	Alliance, therapeutic trust	Neutral, evidence-led

8.2 Opinion and fact: why the expert is the courtroom's exception

A court is a machine for finding facts and drawing inferences from them, and it reserves the drawing of inferences to itself. The ordinary witness is therefore confined to **fact evidence**: what they personally perceived - saw, heard, did, recorded. They are not permitted to offer their conclusions, because inference is the court's own work. The expert is the deliberate exception to this rule. Where a question turns on specialised knowledge the lay judge does not possess, the law admits **opinion evidence** from a person qualified in that field, precisely so the court can reason about matters it could not otherwise understand.

The distinction has a direct and frequently examined consequence for the psychiatrist. A treating psychiatrist summoned to testify about a patient they have managed is, in that capacity, usually a witness of fact: they speak to their own observations, their records, the treatment given. That is fact evidence, even though the witness happens to be an expert by training. Giving an opinion on a legal question about someone the witness has not evaluated for that purpose is a different act, requiring the expert footing. The same psychiatrist may therefore be a witness of fact in one proceeding and an expert in another; the discipline is to know, at every moment, which capacity is being exercised, because the permissions and the duties differ.

8.3 The advisory character of the opinion

Because opinion is admitted only by way of exception, the law is careful to fix its weight. The governing Indian authority is **Ramesh Chandra Agrawal v. Regency Hospital Ltd.** (Supreme Court, **2009**), which states the principle plainly: an expert is not a witness of fact, and the evidence is really of an advisory character. The expert's duty is to furnish the judge with the necessary scientific criteria for testing the accuracy of the conclusions, so as to enable the judge to form an independent judgment by applying those criteria to the facts proved in the case. It is not the province of the expert to act as judge or jury; the court is not bound by the opinion, and weighs it against the reasons and the data the expert has actually supplied.

2009

RAMESH CHANDRA AGRAWAL: THE SUPREME COURT ON THE EXPERT'S ROLE

Two things follow, and both are examinable. First, the opinion is only ever an aid to the court's own reasoning, never a substitute for it, so a decision-maker who simply adopts an expert's conclusion has abdicated the very function the law reserves to it. Second, and more useful at the bedside of report-writing, an opinion carries weight in large part according to how far it exposes the criteria and data on which it rests. A bare conclusion, however eminent its author, gives the court nothing to test and therefore earns little. The reasoning is the evidence; the conclusion is merely its endpoint.

> An expert witness is not a witness of fact: the opinion is advisory only, and the court, never bound by it, forms its own independent judgment on the reasons and data supplied.

RULE **The expert advises; the court decides.** Expert evidence is of an advisory character. Its job is to hand the court the scientific criteria for testing a conclusion, not to deliver the conclusion the court is bound to accept. Weight tracks the transparency of the criteria and data offered.

8.4 Objectivity, and the partisan-expert trap

If the opinion is advice to the court, then the expert's overriding duty runs to the court and to the truth, not to whoever pays the fee. This is the ethical spine of the role and the point at which it most often fails in practice. The **partisan expert** - the hired opinion that shades every ambiguity in the instructing party's favour - is not merely distasteful; it is worthless in exactly the terms the governing authority sets out, because an opinion shaped to a conclusion cannot honestly furnish the criteria by which that conclusion could be falsified. Independence is not a courtesy the expert extends to the other side; it is the condition on which the evidence has any value at all.

Signs that an opinion has slipped from expert to advocate include:

- a conclusion stated with a confidence the underlying data cannot support;
- selective use of the record, with inconvenient findings omitted rather than addressed;
- straying beyond the witness's actual field of competence;
- answering the ultimate legal question directly instead of supplying the material the court needs to answer it.

TRAP **Deciding the ultimate legal issue.** The expert may give the clinical opinion, including whether the person was, by reason of unsoundness of mind, in a particular mental state, which the evidence code names as a paradigm expert question. What the expert must not do is announce the verdict: whether the statutory defence is made out, or whether the doctor is legally liable. That legal conclusion is the court's province. The expert furnishes the clinical criteria and findings; the judge, not bound by the opinion, applies the law.

IN INDIA

Indian courts treat expert medical and psychiatric opinion as advisory rather than conclusive, and the Supreme Court's statement of that position is the authority discussed above. A well-reasoned report that lays out its criteria and data will be given weight; an assertion offered on authority alone will not. The practical lesson for the Indian evaluator is to write for a reader who is entitled to disagree.

8.5 From consulting room to witness box

The expert's product is the written report, and it is prepared on the assumption that it will be read by an adversary and tested under cross-examination. A defensible report therefore does the opposite of what a clinical note does for a colleague: it spells out its own workings so that a hostile reader can retrace them. The psychiatrist states the instructions received and the question asked, records who was examined and on what material, distinguishes what was observed from what was inferred, and confines every opinion to matters within genuine competence. Where the data are thin or the literature divided, the honest report says so, because a candid limitation strengthens the parts that remain and a concealed one collapses the whole under cross-examination.

A defensible expert report characteristically:

- identifies the instructing party, the question, and the material relied on;
- separates facts observed from opinions drawn;
- gives the reasoning and criteria behind each opinion, not the conclusion alone;
- stays within the author's field and flags the limits of the data.

GOOD TO REMEMBER

Keep the two roles physically separate whenever you can: if you are the treating psychiatrist, resist accepting an expert brief on your own patient, and if you must give evidence about them, give it as a witness of fact - what you saw, recorded and did. Because those treating records can themselves be summoned as fact evidence, contemporaneous, legible and complete documentation is a medico-legal protection long before any court is involved.

PITFALL

A common and damaging real-world error is not a courtroom blunder but an acceptance made months earlier: agreeing to serve as the court's expert on a patient one is actively treating. The clinician believes they are best placed because they know the patient, but they arrive with a therapeutic loyalty and a prior belief that no amount of good faith can neutralise, and the resulting opinion is both ethically compromised and easily discredited. Decline the dual role at the outset, and refer the evaluation to an independent colleague.

8.6 Where the expert role meets the rest of forensic practice

The advisory posture set out above is not confined to one kind of case; it is the common footing on which the psychiatrist enters every legal forum. The psychiatric assessment of an accused,

whose procedural pathway of court referral and reporting is dealt with elsewhere in this chapter, is an application of exactly this role: the psychiatrist furnishes the court with clinical findings and criteria, while the substantive question of criminal responsibility, and the tests and burden of proof that govern it, belong to the Mental health legislation and forensic psychiatry notes. In a professional-negligence action the standard of care, taught elsewhere in this chapter, is itself proved through expert testimony about accepted practice, so the credibility of the whole claim can turn on how transparently that expert reasons. And the rules of evidence and the court structure that decide how an opinion is admitted and received, also treated elsewhere in this chapter, are the procedural frame within which the advisory character of the opinion actually operates.

The unifying idea. Across all of these settings the psychiatrist is doing one thing: translating clinical observation into criteria a court can test, while leaving the decision to the court. Hold the treating role and the expert role apart, remember that opinion is admitted only as an aid and never as a verdict, and the harder forensic tasks in this chapter become variations on a single, well-understood discipline.

9 · Boundary violations and ethics of the therapeutic relationship

The therapeutic relationship is the instrument of psychiatric treatment, and boundaries are what keep that instrument safe to use. Psychiatry works through a relationship in which a distressed person discloses the most private material of a life to a clinician trusted to hold it and to act only in that person's interest. That trust rests on an asymmetry of power, knowledge and dependence that does not reverse itself, and it is that asymmetry which makes the relationship both healing and dangerous. The ethics of the therapeutic relationship is the discipline of managing that danger, and its central examinable idea is the distinction between a departure from the frame that remains safe and one that has become harmful. A candidate who can define a boundary crossing and a boundary violation, hold the two apart on stated grounds, and trace the progression that carries one into the other has this topic; one who treats every deviation as misconduct, or reserves the word violation for sexual contact alone, has misunderstood it.

Fig 26.7 A boundary crossing is a departure from the usual therapeutic frame that may remain clinically justified; a boundary violation exploits the asymmetry of the relationship and harms the patient. Context, purpose, cumulative drift and patient welfare determine the distinction.

What is owned here is the doctrine of the relationship itself. The four principles of biomedical ethics, informed consent, confidentiality and its limits, and the professional-conduct codes each have their own treatment in this chapter and are named here, not re-derived; so too the disciplinary, civil and consumer-forum consequences of a breach.

Fiduciary	Clinician	Absolute
THE NATURE OF THE DUTY THE RELATIONSHIP IMPOSES	WHO OWNS THE BOUNDARY, IN EVERY CASE	THE PROHIBITION ON SEXUAL CONTACT WITH A CURRENT PATIENT

9.1 The therapeutic frame and the fiduciary duty

Every treatment proceeds inside a set of expectations about how the clinician and patient will relate: the length, time and place of appointments, what is discussed, the handling of money, touch and personal information, and the understanding that the encounter exists for the patient's benefit alone. This set of expectations is the **therapeutic frame**, and boundaries are its edges.

They are not coldness or rigidity but the conditions under which a patient can safely regress, disclose and depend, knowing the clinician will not exploit the openness that treatment requires.

The frame is necessary because the relationship is a **fiduciary** one: the patient entrusts their welfare to a clinician who holds greater power and knowledge and is bound, in return, to place the patient's interests first, subject to the law and to the narrowly defined duties owed to others, and never to convert the relationship to their own advantage. Two features of psychiatric treatment sharpen this duty beyond that of most specialties. The first is **transference**, in which the patient unconsciously experiences the clinician through the template of earlier significant relationships, investing them with an authority, intimacy or idealisation carried from those earlier relationships rather than earned by the real person; realistic reactions to what the clinician actually says and does run alongside it, and the two are not always easy to separate. The second is **countertransference**, the clinician's own emotional responses to the patient, ordinary and useful in the work but which, unexamined, can pull the clinician toward gratifying their own needs under the guise of helping. Because transference makes the patient especially susceptible and countertransference makes the clinician especially fallible, responsibility for the boundary can never be shared with the patient; it rests wholly and permanently with the clinician.

RULE **The relationship is fiduciary, and the duty to maintain its boundaries rests entirely with the clinician, never with the patient.** Because transference and the power asymmetry leave the patient unable to protect themselves within the relationship, the patient's apparent willingness, invitation or even initiation never transfers responsibility: whatever the patient does, the clinician is answerable for the boundary, at every stage.

9.2 Boundary crossing versus boundary violation

The pivotal distinction of this topic is between two kinds of departure from the frame. A **boundary crossing** is a deviation from usual practice that is minor, non-exploitative and potentially benign or even helpful, and that can be openly acknowledged and discussed. Offering a distressed patient a tissue, briefly extending a session at a moment of crisis, or a small self-disclosure that normalises a fear may all be crossings: they step outside the frame, but they serve the patient, are reversible, and survive being talked about in supervision or written in the notes.

A **boundary violation** is a departure that is exploitative and harmful, that serves the clinician's needs rather than the patient's, and that damages the treatment. The difference is not the size of the step but its direction and effect: whose need it meets, whether it can be reversed, whether it can be discussed honestly, and whether it stands alone or forms part of a drift away from the patient's interest. A crossing that recurs, escalates, is concealed and begins to gratify the clinician has stopped being a crossing. The two therefore describe points on a single continuum, not unrelated categories, which is why the same act can be either depending on context and motive.

AXIS	BOUNDARY CROSSING	BOUNDARY VIOLATION
WHOSE NEED IS SERVED	The patient's; consistent with the treatment	The clinician's; the treatment is subordinated to it
EFFECT ON THE PATIENT	Neutral or beneficial	Harmful; exploits the patient's vulnerability
EXPLOITATION	Absent	Present, by definition
DISCUSSABILITY	Openly acknowledged and documented	Concealed, rationalised or kept secret
REVERSIBILITY	Reversible; the frame is easily restored	Damages the frame, often irreparably
PATTERN	Isolated and self-limiting	Recurrent, escalating, part of a drift

MNEMONIC

Whose need? Reversible? Discussable? A pattern?

The four questions that sort a crossing from a violation. **Whose need** is served, the patient's or the clinician's (beneficence against self-interest). **Reversible**, can the frame be restored or is the harm done (non-maleficence). **Discussable**, could it be said aloud in supervision and the notes, or must it be hidden. **A pattern**, does it stand alone or is it one step in an escalating drift. Answer patient, yes, yes, no and it is a crossing; the reverse and it is a violation.

9.3 The domains in which boundaries operate

Boundaries are not confined to physical contact; they run through every dimension of the clinical encounter, and a violation can occur in any of them. Naming the domains matters because clinicians tend to watch only the most obvious one and miss a breach in another. The recurring domains are:

- **Role.** Keeping the clinical role distinct from social, business or personal roles; a **dual relationship** arises when a second relationship is superimposed on the treating one.
- **Time and place.** The scheduling, duration and location of contact; appointments drifting to the end of the working day, lengthening without clinical reason, or moving outside the clinical setting.
- **Money and gifts.** Fees, business dealings, borrowing or lending, and the giving or receiving of gifts and services beyond token courtesy.
- **Self-disclosure and language.** How much of the clinician's own life enters the room, and a shift toward an intimate or personal register.
- **Physical contact.** Touch of any kind, at the far end of which lies sexual contact, the gravest breach of all.

The value of the list is that it makes the drift visible. Serious violations rarely begin with the act that finally destroys the treatment; they begin with small, defensible-looking changes across

several domains at once, each innocuous in isolation. Watching all the domains, not only the physical one, is how a clinician catches a problem while it remains a crossing.

9.4 The slippery slope

The **slippery slope** is the observation that boundary violations characteristically develop by gradual progression rather than a single decisive act. A clinician rarely moves directly from correct practice to gross exploitation; instead a series of minor crossings accumulates, each normalising the next, until the relationship has slid far from its therapeutic purpose. A common progression begins with a subtle shift toward the personal and a growing sense that one patient is special, moves through appointments lengthened or rescheduled to the end of the working day, extra-clinical contact, the exchange of confidences and gifts, and meetings outside the clinical setting, and ends in sexual involvement. The precise sequence varies, but the shape is consistent: incremental, mutually reinforcing steps, each small enough to be rationalised.

The mechanism is what makes the concept clinically useful rather than merely descriptive. Because each step is small, it evades the clinician's own alarm; because transference makes the patient receptive and countertransference makes the clinician gratified, both are drawn along the slope rather than pulled back; and because the steps are concealed, the ordinary corrective of open discussion never operates. The practical implication is decisive: a violation is reliably prevented early, at the first crossings and the first stirrings of specialness, not at the edge of the sexual act, where the clinician's judgement has usually already been captured. This is why the doctrine treats trivial-looking early crossings with a seriousness that seems disproportionate until the trajectory is understood.

TRAP **Equating any boundary crossing with a boundary violation, or reserving the word violation for sexual contact alone.** Both errors lose marks. A crossing is not automatically wrong; a rigidly withholding clinician who never adapts the frame may serve the patient badly, and a crossing is distinguished from a violation by exploitation, harm and concealment, not by the mere fact of deviation. Equally, violations occur across every domain, and financial, social or dual-relationship exploitation is a genuine violation even where no sexual contact occurs. The candidate who defines the distinction correctly, and locates sexual misconduct as the gravest point on a continuum rather than the whole of it, answers the question actually asked.

9.5 Sexual misconduct: the paradigm violation

Of all boundary violations, sexual contact with a patient is treated as categorically the most serious. **Sexual misconduct** covers any sexual contact, relationship or exploitation of a patient by the treating clinician, and both professional consensus and the conduct codes treat it as absolutely prohibited for the duration of the clinical relationship. The prohibition is not softened by the patient's apparent willingness, and apparent consent is never a defence: even where the patient appears willing and has full decision-making capacity, the power asymmetry and the transference that treatment generates mean that agreement cannot make the clinician's sexual conduct permissible, and responsibility for avoiding exploitation remains entirely with the clinician. This clinical meaning of consent is distinct from the criminal-law meaning of consent in sexual-offences law, which has its own treatment in this chapter.

The harm is severe: exploited patients suffer damage resembling other betrayals of trust by a person in authority, including lasting difficulty ever trusting a clinician again. The former-patient question is the harder discrimination and a favourite of examiners. Because the transference and the imbalance of power do not end cleanly at the final appointment, the strictest professional position, often summarised as once a patient, always a patient, holds that a sexual relationship with a former patient remains unethical for as long as the residue of the therapeutic power imbalance persists. A candidate should state the in-treatment prohibition as absolute and treat the post-termination question as governed by the persistence of that imbalance, not by the mere ending of treatment. Where the patient is a minor, the conduct additionally engages the child-protection statutes, which belong to the Child psychiatry: assessment, treatment, services and protection notes and are named here rather than worked through.

GOOD TO REMEMBER

Treat the feeling of specialness as a clinical sign, not a private matter. When a clinician notices that one patient has become an exception, wanting to give them extra time, thinking of them between sessions, quietly bending the frame in their favour, the right response is to take it to supervision, not to act on it. Boundaries are protected far more reliably by routine self-monitoring, consultation and honest documentation than by willpower at the edge of the slope. The safe working test is that anything you would be unwilling to record in the notes or describe to a supervisor is already the problem.

9.6 Risk, prevention and the Indian setting

Boundary violations are not confined to a few predatory clinicians; ordinary practitioners are vulnerable under particular conditions. Recognised risk situations include the clinician passing through personal crisis, loss or loneliness, professional isolation without supervision, idealising or being idealised by a patient, and the seductive belief that this relationship is a unique exception to the rules. The protective measures follow from the mechanism of the slippery slope: regular supervision and consultation that make countertransference discussable, transparent documentation, attention to all the boundary domains rather than only the physical, judicious use of a chaperone, and a low threshold for referral where a conflict of interest cannot be contained.

The professional-conduct codes give this discipline its formal force. The duty not to exploit the therapeutic relationship for personal, social, business or sexual gain is stated in those four terms by the Indian Psychiatric Society's code of ethics; the operative statutory conduct code supplies the disciplinary consequence in its own terms, which are set out in this chapter's account of the professional codes of ethics and applied here rather than restated.

IN INDIA

The unavoidability of dual relationships in Indian practice makes the boundary discipline more demanding, not less. In a small town or close community the psychiatrist often cannot be a stranger to the patient outside the clinic, and shared social circles and family referrals are the norm. The frame then has to be defended deliberately: naming the clinical role where social and clinical worlds overlap, declining business or financial entanglement with patients, guarding confidentiality where relationships are interconnected, and referring on where a conflict of interest cannot be managed. The overlap of worlds is a fact of the setting; the exploitation of it is still a violation.

9.7 Accountability and the currency of the code

A proven boundary violation engages several distinct forms of accountability at once, and a complete answer names each. It is professional misconduct under the conduct code and can lead to disciplinary action up to erasure from the medical register. It can support a civil claim in professional negligence, whose elements must still be proved, and a deficiency in service can be pursued in the consumer forum; both have their own accounts in this chapter and are named here, not reworked. Where the conduct is itself criminal, the ordinary criminal law applies. A single violation can be actionable at once before a disciplinary body, a civil court and a consumer forum, and none forgives the others.

One currency point must be got right, because examiners use it to separate candidates. The provisions a clinician is held to are those of the operative Medical Council professional-conduct code; a more recent set of registered-medical-practitioner conduct regulations was notified by the National Medical Commission, came into force on publication, but was then held in abeyance and is not operative until a further Gazette notification. The earlier Council code therefore remains operative, including for a boundary violation. The exact editions, citations and dates belong to this chapter's account of the professional codes of ethics and are not asserted here.

PITFALL

Anchoring a misconduct analysis to the most recently notified conduct regulations as though they were the live code. It is natural to assume the newest professional-conduct regulations must be in force, and a clinician who does so will apply the wrong standard to a boundary breach. The recently notified registered-medical-practitioner conduct regulations came into force on publication but were then placed in abeyance and are not currently operative, so the earlier Medical Council code remains operative. Judging a disciplinary matter against a code not yet in force is a live-practice error with real consequences.

A boundary crossing is a minor, non-exploitative, discussable departure from the therapeutic frame that may even help the patient; a boundary violation is an exploitative, harmful departure that serves the clinician and betrays the fiduciary duty, and the slippery slope is the progression of unmonitored crossings that carries one into the other; sexual contact with a current patient is the paradigm violation, absolutely prohibited and never excused by apparent consent, because the patient's willingness cannot make the clinician's conduct permissible, and responsibility for every boundary rests always with the clinician.

10 · Ethics of research, publication and conflicts of interest

Why the marks sit here. Research is where a psychiatrist's two loyalties collide most sharply. Ordinary clinical work exists to help the person in the room; research exists to answer a question that may benefit no current patient at all. When the same doctor holds both roles over the same person, the informal safeguards of the consulting room are no longer enough, and a candidate is expected to show exactly how the ethical frame changes once a patient becomes a participant. Publication and conflict of interest share this subtopic because they are the downstream expressions of the same problem: whose interest is being served when data are gathered, written up and rewarded.

What this topic genuinely owns is the ethics specific to doing and reporting research: the way the general duties are re-shaped in the research setting, the Indian regulatory frame for clinical research, the management of competing interests, and the integrity of the published record. The principles of biomedical ethics and the elements of valid consent are taught elsewhere in these notes and are only invoked here, never relisted.

19(C)	2018
THE CONDUCT REGULATION TYING RESEARCH TO ICMR GUIDELINES	THE YEAR THE SUSPENDED 2023 CODE CITES FOR THE DRUG-TRIAL RULES

10.1 The dual role: treatment versus research

Clinical care is governed by a primary loyalty to the person in the room, so that, subject to the law and the narrow duties owed to others, everything the psychiatrist does is meant to help the patient being treated. Research answers to a different master. Its purpose is to produce generalisable knowledge, and the participant may gain nothing personally from taking part. This is not a flaw of research; it is its definition, and it is precisely why research needs a stricter apparatus than treatment. The error the examiner is probing is the **therapeutic misconception**: the participant, and sometimes the doctor, believing that study procedures are individualised treatment chosen for this person's benefit, when in fact they are dictated by a protocol and by the needs of the question.

Because the two roles pull in different directions, they must be held analytically apart even when one person carries both. The accompanying comparison sets out the axes on which they diverge, and the pattern to carry is that at every axis the research column demands an external check that clinical care can leave implicit.

AXIS	CLINICAL CARE	RESEARCH
Primary purpose	Benefit this patient	Generate generalisable knowledge
Duty runs to	The individual before you	The participant, whose welfare stays primary over science and society
What consent is to	An offered treatment	Voluntary participation, freely withdrawable
Independent oversight	Clinical governance	A prior, formal ethics-committee review
How risk is justified	Expected benefit to the patient	A favourable balance of risk against knowledge, with added protections

10.2 Informed consent for research

The same requirements, at a higher bar. The requirements of valid consent are taught in full under informed consent in psychiatry in these notes and are not reworked here. What changes in the research setting is their weight and their content. Voluntariness carries far more strain, because the person is often the doctor's own patient and may agree out of gratitude, dependence or fear that refusal will sour their care. The disclosure must be fuller and more honest than a treatment discussion, and it must be explicit about the things a therapeutic conversation can take for granted. A research consent conversation should establish:

- that the activity is research rather than individualised treatment, and what it is trying to find out;
- that participation is voluntary and that refusal will not compromise their ongoing care in any way;
- the right to withdraw at any time, without penalty and without giving a reason;
- the foreseeable risks and burdens, and the honest possibility of no personal benefit;
- the alternatives, including the standard treatment they would receive outside the study;
- how the confidentiality of their data will be protected, the duty and its permitted exceptions being set out under confidentiality and its limits in these notes.

Where a prospective participant's capacity to consent is impaired, as it may be in acute psychosis, severe mood disorder or cognitive impairment, the additional protections of the mental-health law apply, and these are addressed in the Mental health legislation and forensic psychiatry notes. Research involving children carries its own protective framework, addressed in the Child psychiatry: assessment, treatment, services and protection notes. The candidate's task is to name these safeguards and route to them, not to reconstruct them.

TRAP **Treating research consent as ordinary treatment consent.** Candidates assume that a patient who has agreed to be in a trial has consented the way they consent to a prescription. Research consent is a distinct, heavier act: it must name the research nature explicitly, promise that refusal will not affect care, and preserve an unconditional right to withdraw. A consent that a treating clinician obtains from their own patient without these features is the classic setting for the therapeutic misconception, and it is exactly what the examiner wants flagged.

10.3 The Indian regulatory frame

Research on patients or volunteers in India is governed by dedicated national instruments rather than by clinical convention. Under the newer National Medical Commission professional-conduct Regulations, at regulation **19**(C), clinical drug trials and other research involving patients or volunteers must comply with **ICMR guidelines** and the **New Drugs and Clinical Trials Rules, 2018** - the year as the suspended 2023 regulation itself records it. Consent that is not taken in accordance with those guidelines shall be construed as professional misconduct. The force of that phrasing repays attention: in that code's own terms a defect in the research consent process is not a documentary technicality but misconduct. Because that code is in abeyance, what makes such a defect actionable today has to be found in the operative conduct code, in the national research guidelines and the drug-trial Rules, and in the conditions of the ethics committee's own approval.

Two layers therefore sit over the same activity. The research-conduct layer routes the study through independent ethics-committee review and the national research guidelines; the professional-conduct layer makes a breach of those requirements a matter for the regulator. A candidate should be able to say that Indian research is anchored to primary national instruments, and should be careful about which conduct code is actually in force, because that is where the confident answer most often goes wrong.

IN INDIA

The practical machinery a clinician meets is the registered ethics committee and the national ethical guidelines for biomedical and health research. Regulated drug trials sit additionally under the New Drugs and Clinical Trials Rules and their consent and oversight requirements. The suspended 2023 professional-conduct code expressly requires the practitioner to disclose the dual role of treating doctor and investigator; independently of that suspended text, such disclosure remains sound ethical practice under the conflict-of-interest and consent principles, so that the participant understands the two hats being worn at once.

PITFALL

Do not cite the newer National Medical Commission Regulations as the professional-conduct code currently in force. They were notified and then held in abeyance, so the earlier Medical Council of India professional-conduct code remains the operative one. The codes themselves are set out under the Indian Psychiatric Society code of ethics in these notes; here the point is only that the research and conflict-of-interest duties are read from the code that actually governs, not from a notified-but-suspended one.

10.4 Conflict of interest

A **conflict of interest** arises whenever a secondary interest threatens to distort the primary duty owed to the patient or participant. The secondary interest need not be sinister: industry sponsorship, a gift or honorarium, academic advancement, the desire to publish, or simply the pressure to meet a recruitment target can all bend judgement without any conscious intent to do harm. That is why the profession treats the situation, and not merely the bad act, as the thing to manage.

The code does not pretend such situations can always be abolished. It requires the practitioner to recognise them, and to avoid or minimise them; where a conflict cannot be removed, the patient's interest should take precedence over any other consideration, and the honest course is to disclose the competing role rather than conceal it. In the research setting this bites hardest when the investigator is the patient's own psychiatrist, which is why separating the consent conversation from the treating relationship is the single most protective step available.

RULE **Disclosure does not resolve a conflict; it only makes it visible.** Naming a competing interest is the beginning of managing it, not a substitute for putting the patient first. Where the two genuinely cannot be reconciled, it is the research that yields, not the patient's welfare.

GOOD TO REMEMBER

Whenever you recruit your own patient into a study, say so out loud. Name your dual role, make explicit that declining will not change their care, and record that you did both. Routing the consent through an independent colleague, rather than obtaining it yourself at the bedside, protects the patient from the therapeutic misconception and protects you from the charge of exploiting the relationship. The ethics committee's part in this is the prior review that approves the consent process; it does not take the consent for you.

10.5 Publication and research integrity

The published record is the currency of science, and guarding its integrity is an ethical obligation continuous with the duties owed to participants. If consent protects the person, publication ethics protect everyone who will later rely on the result. Authorship is the first pressure point: it should reflect a genuine substantial contribution together with accountability for the work, and the recognised authorship criteria exist to keep credit and responsibility joined. Where they come apart, the familiar abuses appear:

- **gift authorship**, awarding or accepting authorship without a real contribution, often to a senior figure;
- **ghost authorship**, omitting a genuine contributor, classically an industry-employed writer;
- **redundant publication**, presenting the same data as though new, including slicing one study into several thin papers;
- **plagiarism**, presenting another's work, words or ideas as one's own;
- undisclosed conflicts of interest, and the selective or non-reporting of unwelcome results.

Beneath these lie the cardinal breaches of integrity, the ones that corrupt the data themselves rather than the credit around them. Prospective registration of trials, transparent reporting of methods and outcomes, and a willingness to share data are the countermeasures the field has adopted, and they matter clinically because the psychiatrist at the other end of the literature prescribes on the basis of what was published.

MNEMONIC

Fabricate, Falsify, Plagiarise

The three cardinal breaches of research integrity: inventing data that were never collected, altering data that were, and passing off another's work as one's own. Everything else, from gift authorship to redundant publication to a hidden conflict of interest, erodes the record more quietly, but these three are the ones that make a result simply false.

Research does not suspend the psychiatrist's duty to the patient; it adds a second, competing duty, and when the two collide the patient's welfare comes first. In India the research and conflict-of-interest duties are read from the professional-conduct code that is actually operative, research on patients or volunteers must comply with the national research guidelines and the drug-trial Rules, and a consent taken outside them is a substantive breach and not a paperwork slip, though which code makes it actionable depends on the code in force.

11 · Medical records, documentation and certification standards

Every duty in this chapter leaves a paper trail, and the paper is where the duty is proved or lost. Consent, the mental state examination, the risk assessment, the disclosure made to a third party, the opinion handed to a court - each of these is invisible after the encounter unless it was written down, so the record is the physical substrate on which the whole of forensic ethics rests. The marks in this topic are for knowing what a defensible record contains, how long it must be kept and who may see it, and the standard a psychiatrist is held to when signing a certificate. These are discrete, quotable points, and each is a place a hurried clinician, and a hurried candidate, comes to grief.

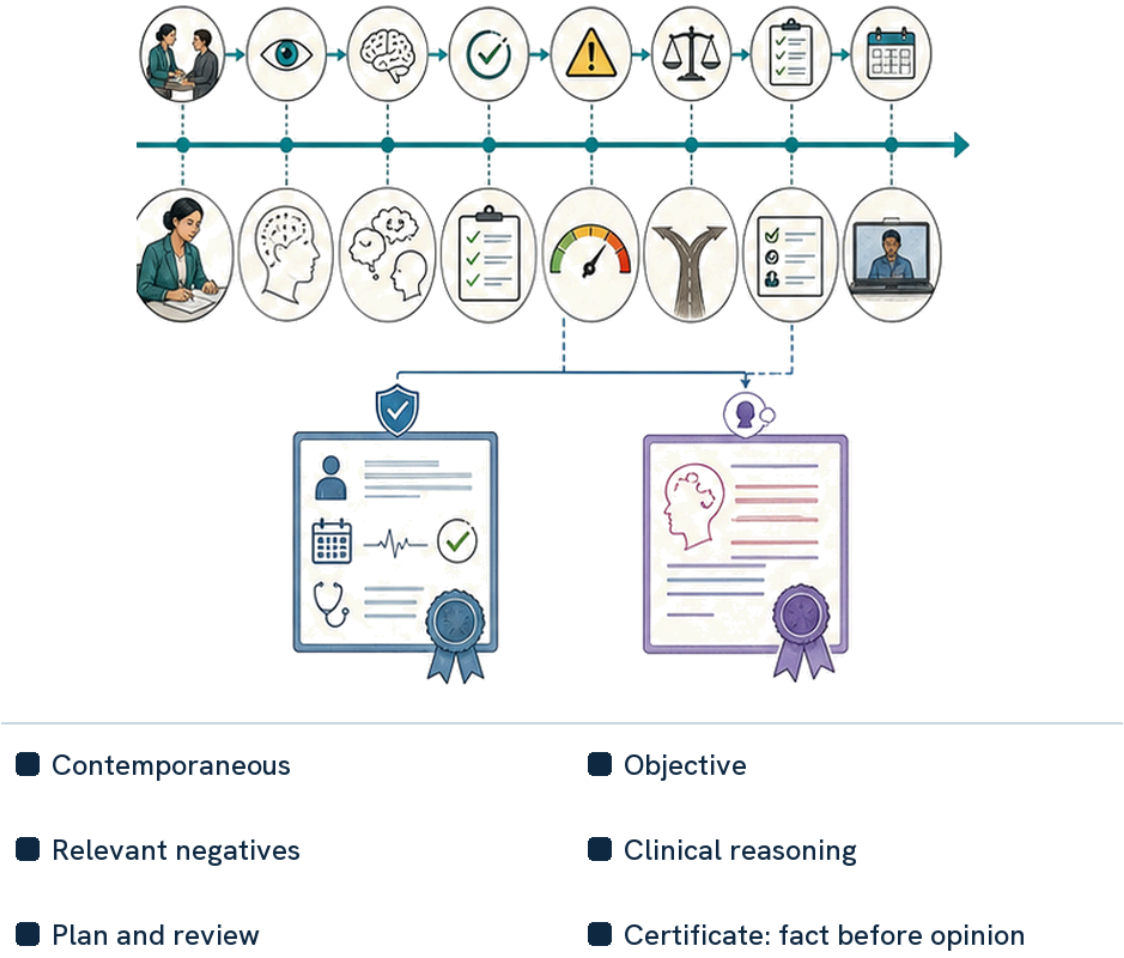

Fig 26.8 A defensible psychiatric record is contemporaneous, objective and sufficient to show assessment, relevant negative findings, clinical reasoning, decisions and review. A certificate separates verified fact from professional opinion and states its purpose.

This fragment owns the record itself: its making, its keeping and the certificates drawn from it. It does not own the confidentiality rule that governs when the contents may be released, which belongs to the separate account of confidentiality and its limits in this chapter; nor the professional-conduct code whose provisions it applies, which belongs to this chapter's account of the professional-conduct codes. Keeping those boundaries clear - the document here, the disclosure rule there, the code elsewhere - is the discipline the examiner is testing.

11.1 Why the record carries the marks

The **medical record** is at once a clinical instrument and a legal document, and the two functions pull in the same direction. Clinically it is the memory of the treating team, the substrate of continuity when care passes between hands, and the audit trail that lets a later reviewer reconstruct what was known and decided at each point. Legally it is the doctor's first and best evidence: in any dispute over what was done, the contemporaneous note carries a weight that

recollection years later cannot, because it was made before anyone had a reason to shade the account. The medicolegal maxim - that what is not recorded is, in the eye of the court, treated as not done - is less a rule of evidence than a warning about the burden a silent chart throws back on the doctor.

Psychiatry sharpens this. The findings a psychiatrist relies on - the form and content of thought, the assessment of capacity, the judgement that a patient did or did not pose a risk - are matters of clinical opinion that leave no radiograph and no laboratory value behind them. If the reasoning is not on the page there is nothing to show it was ever done, and a note that records only a conclusion is far weaker in defence than one that shows the work.

> In law a clinical entry that was never recorded is hard to prove was ever done, and a silent chart throws the burden back on the doctor, so the record is the psychiatrist's primary evidence of what was known and decided.

11.2 The anatomy of a defensible entry

A record earns its evidentiary weight through the manner of its making. The qualities a court looks for, and that distinguish a defensible chart from a liability, are few and can be stated plainly:

- **Contemporaneous.** Made at the time of the encounter or as soon as practicable after it, so that the entry precedes any dispute and cannot be said to have been composed for the occasion.
- **Legible and attributable.** Readable, dated and timed, and signed with an identifiable name and designation, so that every entry can be traced to an author.
- **Accurate and factual.** Recording observation and reasoning, not speculation or gratuitous remarks about the patient, which serve no clinical purpose and read badly when the file is opened in public.
- **Complete for its purpose.** Carrying the findings, the assessment and the plan, and, for the decisions that matter medicolegally, the reasoning - the consent taken, the capacity judged, the risk weighed.
- **Unaltered.** Corrected only in the open: an error struck through with a single line that leaves the original readable, initialled and dated, never erased, overwritten or made to disappear.

The last of these is the one that turns a weak case into an indefensible one. An honest error in a note is forgivable and often irrelevant; a note that has been quietly changed after the event destroys the credibility of the whole record and, with it, the doctor's. This is why **tampering** - backdating, insertion, obliteration - is treated so gravely, and why the correct way to amend is always additive and transparent rather than concealing.

RULE **A record's value is a function of its being contemporaneous and unaltered; a correction is made by open amendment, never by erasure.** The point is not perfection at the moment of writing but honesty over time. An entry made late should be dated to the true date of writing and marked as retrospective, not slipped in under an earlier date, and an error should be struck through so the original stays legible, with the correction, initials and date beside it. A chart that can be shown never to have been secretly changed will defend a clinician who erred in good faith; a chart that has been doctored will sink one who did not.

GOOD TO REMEMBER

Write the note as though it will be read aloud in a courtroom with the patient present, because one day it may be. Record the reasoning behind decisions that carry legal weight - why capacity was accepted, why a risk was judged manageable - not just the conclusion. If you must add to a note after the event, say so openly and date the addition to the day you wrote it; the habit costs seconds and is the best protection you have.

11.3 Retention, ownership and the patient's right of access

Two questions follow the making of a record: how long it must be kept, and who may have it. On ownership the settled position is that the custodian - the institution or the self-employed practitioner - holds and preserves the physical record, while the patient has an enforceable right of access to the information within it and to a copy of it. The patient is entitled to a copy, not to carry off the original, and the duty to supply it runs to the patient, an authorised attendant, or a legal authority making a proper request.

3 years	5 working days
INPATIENT RECORD RETENTION UNDER THE 2023 REGULATIONS (IN ABEYANCE)	SUPPLY OF RECORDS ON A PROPER REQUEST

Currency is where this topic is won or lost. The clearest recent statement of a retention standard is the National Medical Commission's Registered Medical Practitioner (Professional Conduct) Regulations 2023; but those Regulations, though notified, were held in abeyance shortly afterwards and are therefore not the operative code. The live professional-conduct code remains the Indian Medical Council (Professional Conduct, Etiquette and Ethics) Regulations 2002, whose provisions are set out in this chapter's account of the professional-conduct codes. Read with that caveat, the 2023 Regulations provide at Regulation **13** that a self-employed practitioner shall maintain inpatient medical records for **3 years** from the date of last contact with the patient, in a standard **proforma** laid down by the Commission, and that records requested by the patient, an authorised attendant or a legal authority shall be supplied within **5 working days**. The same regulation would also require records to be fully digitised in due course, in compliance with information-technology and data-protection law. All of this describes the suspended 2023 text, not a prediction of the eventual operative code, which a further Gazette notification could revive, amend or replace; the requirement that binds a practitioner today is the one the operative 2002 code lays down.

TRAP **Quoting a retention period without the event it runs from, or across the wrong code.** Under the suspended 2023 Regulations the inpatient clock runs from the date of last treatment contact, not from admission and not from discharge, so a return for follow-up would reset it; the operative 2002 code's own starting point is owned by this chapter's account of the professional-conduct codes and must not be assumed identical to the suspended one. Candidates who quote a bare number of years without its starting point answer half the rule, and the starting point is exactly the half an examiner tests. State the period, the event it runs from, and which code you are quoting, or the figure means nothing.

IN INDIA

Access to records in India runs on parallel tracks. The professional-conduct code obliges the treating practitioner to furnish records on request; for a public hospital the same information is reachable through the right-to-information machinery; and the Mental Healthcare Act carries its own provisions on records and on a patient's access to information, which belong to the Mental health legislation and forensic psychiatry notes and are named, not restated, here. What may actually be released, and when confidentiality is set aside, is governed not by the retention rule but by the duty of confidentiality set out in this chapter's account of confidentiality and its limits.

PITFALL

Quoting the National Medical Commission Registered Medical Practitioner (Professional Conduct) Regulations 2023 as the code in force. They were notified and then held in abeyance, and the operative professional-conduct code remains the Indian Medical Council Regulations 2002. Citing them as live - in a report, an opinion or an examination answer - states as currently binding a code that commenced on publication but was then held in abeyance, and is the commonest currency error here. Name the 2002 code as operative and the 2023 Regulations as notified but in abeyance.

11.4 Certification and the duty of truthful attestation

A **medical certificate** is a formal attestation, over the doctor's signature, of a clinical fact - fitness or unfitness, the presence or absence of illness, a capacity or its lack. Its authority rests entirely on two things: that the signing doctor personally examined the patient and formed the opinion, and that the record behind it supports what the certificate asserts. A certificate is thus only as good as the notes from which it is drawn. The governing duty is truthfulness: the practitioner attests only what has been personally verified and does not issue a false, misleading or loosely worded certificate, a failing the professional-conduct code treats as misconduct, as set out in this chapter's account of the professional-conduct codes.

Psychiatric certification spans a distinctive range, and each type carries its own evidential demand:

CERTIFICATE	WHAT IT ATTESTS	WHAT THE RECORD MUST SHOW
SICKNESS AND FITNESS	Unfitness for, or fitness to resume, work or duty over a stated period	Dated examination findings and the functional basis for the opinion
MENTAL ILLNESS OR SOUNDNESS	The presence or absence of a mental disorder for a defined legal purpose	A recorded mental state examination and the clinical reasoning behind the finding
TESTAMENTARY AND OTHER CAPACITY	That the person could, at the material time, understand and weigh a specific decision	A contemporaneous, decision-specific capacity assessment, ideally at the time of the act
DISABILITY CERTIFICATION	The degree of disability arising from a mental condition, for statutory benefit	Assessment against the applicable schedule, with the instrument and findings on file

Two need a word of care. The **testamentary capacity** certificate is decision-specific and time-specific: it speaks to the person's ability to make a particular disposition at the particular moment, so a general statement of soundness recorded weeks before or after is of little value, and the strongest evidence is a capacity assessment documented at the time of the act itself. And a certificate touching a person's fitness to face criminal proceedings engages criteria that are not this fragment's to teach - the fitness-to-stand-trial criteria belong to the Mental health legislation and forensic psychiatry notes and are named, not restated, here; what this topic owns is the standard for the certificate and the record beneath it, not the legal test it serves.

11.5 When the record becomes evidence

The record's final role is one the clinician does not control. A chart can be summoned to court, produced under a legal authority's request, or made the foundation of an expert opinion, and at that point every quality discussed above is examined by an adversary. The treating record and the forensic report are different documents made for different masters - the first for the patient's care, the second for the court - and the discipline of keeping the treating role separate from the expert role belongs to this chapter's discussion of the psychiatrist as expert witness, named here rather than reworked. What the records topic contributes is the raw material: an opinion offered to a court is only as sound as the contemporaneous notes it is built on, and a report that cannot point back to a dated, unaltered record is opinion floating free of evidence. This is why documentation is not clerical housekeeping but the load-bearing wall of forensic practice, the place where good clinical care and defensible legal standing turn out to be the same thing.

12 · Ethical issues in involuntary treatment, restraint and end-of-life care

Every coercive act in psychiatry has to be justifiable to the person it is done to. Involuntary treatment, physical restraint and decisions about life-prolonging care are the three moments at which what a person wants is most openly at stake: the first two override an expressed wish, while withholding or withdrawing life-prolonging treatment is often instead the way a capacitous refusal or a recorded wish is honoured. They are examined together because one ethical spine runs through all three: coercion is defensible only as the narrowest, most proportionate response

to a genuine necessity, and it must stay answerable to the person's own will and preferences. The statutory machinery that gives that spine force - the emergency-treatment power, the prohibited and restricted procedures, the seclusion-and-restraint provision and the advance directive - is set out in the Mental health legislation and forensic psychiatry notes and is named here, not re-worked.

The four principles of biomedical ethics are invoked by name rather than re-defined, as laid out in this chapter's account of the principles of medical ethics; valid consent belongs to its account of informed consent in psychiatry, and the legal safeguards around seclusion and restraint to its account of the legal aspects of seclusion, restraint and involuntary treatment. What this topic owns is narrower: how those principles are weighed when a patient refuses the treatment thought to be in their interest, and how the weighing shifts from acute crisis, through restraint, to the end of life.

12.1 The ethical spine: least restriction, proportionality and will

Three ideas together decide whether an override of a patient's choice can be defended. The first is the **least restrictive alternative**: of the options that meet the clinical need, the one chosen must intrude least on liberty, bodily integrity and dignity, so restraint is used only when nothing milder will do and is stepped down the moment a gentler option becomes safe. The second is **proportionality**: the degree and duration of coercion must match the seriousness and imminence of the harm it prevents, so open-ended control is never the answer to a transient risk. The third, which most separates the current Indian frame from older paternalism, is that care must be anchored to the person's **will and preferences** - what this patient, knowing themselves, would want - not what a clinician judges good for a generic patient in that position.

These five conditions - necessary, proportionate, least restrictive, time-limited and reviewable - turn a vague sense that coercion is regrettable into a standard testable at the bedside and in the witness box. A measure that fails any one is not merely suboptimal; it is unethical, and increasingly unlawful.

RULE **Coercion is justified only as the least restrictive measure proportionate to a genuine and present necessity, and only for as long as that necessity lasts.** This one sentence is the whole topic in miniature. The question is never simply "is this good for the patient" but "is this the mildest thing that will meet a real and immediate danger, and can I stop it the moment the danger passes". Every rule that follows is an application of it.

MNEMONIC

Necessary, Proportionate, Least-restrictive, Time-limited, Reviewable

The five tests any coercive measure must pass. **N**ecessary (no non-coercive route will do); **P**roportionate (matched to the danger); **L**east-restrictive (the mildest effective form); **T**ime-limited (no longer than the necessity); **R**eviewable (open to reassessment and challenge). A measure you can defend on all five, you can defend anywhere.

12.2 Involuntary treatment and the narrow window of emergency

Treatment given against a refusal is the sharpest form of coercion, and the ethical burden is correspondingly heavy. It rests not on the fact of illness or the clinician's confidence that treatment would help, but on necessity, the absence of a less intrusive route, and wherever possible a substitute decision made through the person's chosen representative. Indian law keeps the power to treat outside ordinary consent exceptional and tightly bounded. The Act's emergency-treatment provision allows treatment only where it is immediately necessary to prevent death or irreversible harm, serious harm by the person to self or others, or serious damage to property flowing from the illness; where the nominated representative is available, emergency treatment is subject to their informed consent; and, most tellingly for proportionality, the power is capped in time. Emergency treatment is limited to **seventy-two hours**, or until the person is assessed at a mental health establishment, whichever comes first, and may extend to **seven days** only during a disaster or emergency declared by the appropriate Government.

Two features are ethically load-bearing. It is a bridge, not a treatment plan: it holds a person safely until proper assessment and consent can happen, which is why it expires. And it is no licence for any intervention the clinician thinks necessary; the emergency power shall not extend to electroconvulsive therapy, which cannot be given under cover of emergency at all. The detailed conditions are set out in the Mental health legislation and forensic psychiatry notes; what matters here is the shape - a power that is necessary, proportionate and self-terminating.

> **GOOD TO REMEMBER**
>
> Your defence for an emergency intervention is a contemporaneous note of the specific danger, the less restrictive options you weighed and why they failed, and the point at which you sought the nominated representative. "The patient was unwell" is not a justification; "the patient was about to act on a command to jump and refused oral medication" is. Record it while it is in front of you: the power is short-lived and the note is what proportionality is later judged against.

12.3 Restraint and seclusion: the least-restrictive ladder

Physical containment is where least restriction does its hardest work, because the measures form a ladder and the demand is to stay as low on it as safety allows and climb down fast. Restraint manages an immediate risk; it is never a treatment or a convenience, uses minimum force for the shortest duration that will contain the danger, and is released the moment that danger recedes.

- **Verbal de-escalation and environmental measures:** the first resort whenever it is safe and feasible, and often enough on their own; the least intrusive rung. Immediate physical restraint may still be required where it is the only means available to prevent imminent and immediate harm.
- **Seclusion and solitary confinement:** not a rung on the ladder at all; a person with mental illness shall not be subjected to seclusion or solitary confinement, which are barred outright and cannot be made lawful by monitoring or a time limit.
- **Physical restraint:** the highest rung short of the floor, minimum force for the shortest time; its exact authorisation and monitoring safeguards are set out in the Mental health legislation

and forensic psychiatry notes.

How physical restraint may lawfully be used, and its safeguards, belongs to the Mental health legislation and forensic psychiatry notes and to this chapter's account of the legal aspects of seclusion, restraint and involuntary treatment; seclusion and solitary confinement of a person with mental illness are prohibited outright. What the ethics fixes as an absolute is the floor beneath the ladder: no person with mental illness **shall be chained** in any manner or form whatsoever, and the bar holds because chaining is degrading regardless of the danger it might contain. Below a certain point, restraint stops being a graded response and becomes an assault on dignity, and the law draws that line without exception.

12.4 The absolute bars and the one conditional gate

The clearest ethical teaching here is the small set of procedures the law places out of bounds, each a point where consent and best interests are judged insufficient protection. Three are absolute. **Unmodified electroconvulsive therapy**, meaning electroconvulsive therapy given without muscle relaxants and anaesthesia, is prohibited outright and cannot be rescued by consent, because the harm it risks is not one a patient can validly agree to run. Sterilisation intended as a treatment for mental illness is prohibited, closing off a historic abuse in which reproductive capacity was removed under a therapeutic pretext. And chaining is barred in any form. The single conditional gate is electroconvulsive therapy for a minor: prohibited by default, but where the psychiatrist in charge of the minor's treatment is of the opinion that it is required, it shall be given only with the informed consent of the guardian and the prior permission of the concerned Board. The structure to carry is an absolute prohibition softened by a narrow, externally checked exception, not by clinician discretion alone.

MEASURE	ETHICAL AND LEGAL STATUS	WHAT THE FLOOR TURNS ON
CHAINING, IN ANY FORM	Barred absolutely	Degrading regardless of the danger contained
UNMODIFIED ELECTROCONVULSIVE THERAPY	Barred absolutely; consent cannot cure it	A harm a patient cannot validly agree to run
STERILISATION AS A TREATMENT FOR MENTAL ILLNESS	Barred	Closes a historic reproductive abuse
ELECTROCONVULSIVE THERAPY FOR A MINOR	Barred by default; a narrow gate	Guardian's informed consent plus prior Board permission
EMERGENCY INVOLUNTARY TREATMENT	Permitted but tightly bounded	Time-limited, and excludes electroconvulsive therapy

TRAP **Believing that consent can license an absolutely prohibited procedure, or that a grave enough emergency justifies electroconvulsive therapy.** Candidates reason that guardian or patient consent makes unmodified electroconvulsive therapy or a "therapeutic" sterilisation permissible, and that a serious enough emergency lets a clinician reach for electroconvulsive therapy. Both are wrong: the absolute bars operate above the level of consent, and the emergency power is defined so as to exclude electroconvulsive therapy. Consent is a gateway for permitted treatment, not a key to prohibited treatment.

12.5 End-of-life care: autonomy at the close of life

The same spine bends at the end of life, but it does not break. End-of-life care tests the will-and-preferences principle at its limit, because the patient may be dying, may have fluctuating or absent capacity, and may have recorded wishes long before the crisis. The psychiatrist's role is often not to decide but to assess: whether this patient can accept or refuse a life-prolonging intervention, and whether a treatable mental illness, depression above all, is so distorting the decision that an apparent wish to die is a symptom to treat rather than a settled preference to honour. Making that discrimination well, and documenting it, is the examinable core of the psychiatrist's end-of-life contribution.

Three distinctions carry the ethical weight. A refusal by a person with capacity, or through a valid advance instruction, is not the same as a request that the clinician actively bring about death; respecting the first is autonomy, the second a separate legal and moral question. Withholding or withdrawing an intervention of no proportionate benefit is not abandonment, because comfort, symptom relief and dignity are owed whatever else is stopped. And the **doctrine of double effect** is the frame invoked for proportionate sedation or analgesia given to relieve suffering where shortening of life is a foreseen risk rather than the aim; a relief-directed intention is necessary to it, but the doctrine's conditions are not reducible to intention alone, so it cannot be cited as a single-condition licence. Wishes recorded in advance should guide care as an expression of will and preferences; the statutory form and force of the advance directive belong to the Mental health legislation and forensic psychiatry notes.

12.6 Will and preferences over best interests

The deepest change the current Indian frame makes is a shift of default. The older posture was best-interests: the clinician decided what was good for the patient and acted on it. The newer posture is **supported decision-making**, in which the patient's own will and preferences govern and the clinician helps the person exercise their capacity rather than substitute a judgment for it. Coercion does not vanish but retreats to the margins, permitted only where a real necessity cannot be met any other way. The broader disability-rights statute underpinning this posture is set out in the Mental health legislation and forensic psychiatry notes.

> **PITFALL**
>
> The commonest real-world error is not cruelty but well-meant paternalism: a clinician sure they know best treats "best interests" as the deciding standard and reads the patient's stated wishes as an obstacle to manage rather than the thing that governs. Under a will-and-preferences frame that inversion is itself the fault. Start from what the person wants, treat capacity as something to be supported rather than presumed absent, and reserve override for genuine, documented necessity.

IN INDIA

The current mental health law is explicitly rights-based: it abolishes chaining outright, channels the most invasive procedures through consent and independent review, keeps the emergency power short and ring-fenced from electroconvulsive therapy, and subordinates treatment to the person's will and preferences rather than an unaided best-interests judgment. The working question shifts from "what is best for this patient" answered alone to "what does this patient want, and what is the least I must do to keep them safe".

94
EMERGENCY TREATMENT: TIME-LIMITED, AND NO ELECTROCONVULSIVE THERAPY

95
PROHIBITED PROCEDURES: CHAINING, UNMODIFIED ELECTROCONVULSIVE THERAPY, STERILISATION

One test governs involuntary treatment, restraint and end-of-life care: coercion is permissible only as the least restrictive, proportionate response to a genuine and present necessity, no longer than that necessity lasts, and always anchored to the person's will and preferences rather than the clinician's unaided view of their best interests; chaining and unmodified electroconvulsive therapy are barred absolutely, sterilisation as treatment is barred, and electroconvulsive therapy for a minor is permitted only through guardian consent and prior Board permission.

13 · Telepsychiatry ethics and social media professionalism

Why the marks are here. Telepsychiatry moved from a fringe convenience to routine practice almost overnight, and the ethics did not keep pace with the technology. The examiner's interest is precise: does the candidate understand that a consultation delivered down a video link owes the patient exactly the same duties as one delivered across a desk, and does the candidate know which code actually governs it in India today. Both halves of the topic - the clinical encounter conducted remotely, and the doctor's separate life on social and public media - test the same instinct, which is that the medium never dilutes the obligation. The currency of the governing rules has also shifted recently, and that shift is a favourite trap.

- Identity and location
- Consent
- Privacy
- Clinical standard unchanged
- Emergency plan
- Professional digital conduct

Fig 26.9 Telepsychiatry changes the medium, not the clinical standard. Identity and location, consent, privacy, documentation and an emergency contingency are established for remote care, while public and social-media conduct remains professionally bounded.

What this section owns is the ethics of remote consultation and of a psychiatrist's conduct in the public digital sphere. The four principles that frame every ethical judgement are set out with the principles of medical ethics in these notes; the anatomy of valid consent is taught with informed consent in these notes; the default duty of confidentiality and the closed list of when a disclosure is permitted are taught with confidentiality and its limits in these notes; and the professional-conduct code itself is treated with the professional-conduct codes in these notes. Those are invoked here, not restated.

13.1 What telepsychiatry is, and why the medium raises the stakes

Telepsychiatry is the delivery of psychiatric assessment, treatment and consultation through information and communication technology when patient and clinician are not in the same room. It spans real-time video and telephone contact and the store-and-forward exchange of clinical information, and it reaches rural and underserved populations that would otherwise

never see a psychiatrist. That reach is its ethical justification and also its hazard: a discipline whose primary instrument is the interview loses part of that instrument at a distance. Subtle motor signs, the smell of alcohol, the atmosphere of a household, the collateral in the waiting room - a proportion of the mental-state examination simply does not travel down a video link. The ethical task is to decide, case by case, whether what remains is enough to discharge the standard of care, and to recognise when it is not.

The peculiar risk of psychiatry is that the high-risk presentations a remote service must be ready for - acute distress, suicidality, psychosis with impaired insight - are exactly those in which a remote encounter is least able to contain risk. Convenience and access must therefore be weighed against the clinical adequacy of the channel, not assumed to settle the matter.

13.2 The regulatory basis, and the currency question

Telepsychiatry in India is not a legal vacuum, but candidates routinely cite the wrong instrument as its source. The recently notified National Medical Commission Registered Medical Practitioner (Professional Conduct) Regulations address it directly: at Regulation **29**, consultation by telemedicine *is permissible*, but only on the condition that it follows the **Telemedicine Practice Guidelines**. That conditionality is the point: the permission and its precondition are a single rule, and telemedicine detached from the Guidelines is not authorised practice. The Guidelines themselves supply the operational scaffold - the modes of consultation, the identification of both parties, the framework for prescribing at a distance - which is applied, not reproduced, here.

The currency trap sits one layer up. Those Regulations came into force on publication but were then held in abeyance and are **not** currently operative; the code that actually governs a psychiatrist's conduct remains the earlier Medical Council of India professional-conduct code, treated with the professional-conduct codes in these notes. The safe posture in the exam and in practice is to take the substance of remote-consultation practice from the Telemedicine Practice Guidelines themselves, and to treat that regulation as notified-but-suspended text rather than transplanting it into the live code. A written answer that names the newer Regulations as the operative code is stating a code that came into force on publication but was then held in abeyance and is not currently operative.

IN INDIA

Remote consultation received its first clear national footing through the Telemedicine Practice Guidelines, later carried into the newer National Medical Commission Registered Medical Practitioner (Professional Conduct) Regulations at Regulation **29**. Those Regulations stand notified but in abeyance; the operative statutory code is still the Medical Council of India professional-conduct code, taught with the professional-conduct codes in these notes. Ground your answer in the live code and read the newer provision for its content.

13.3 Consent, confidentiality and the standard of care at a distance

Every ethical obligation of an in-person consultation survives the move to a screen; what changes is the effort needed to satisfy it. Valid consent, whose three elements are taught with informed consent in these notes, must additionally cover the modality itself: the patient should understand

that this is a remote consultation, its limits, what happens if the connection fails, and how an emergency will be handled. Confidentiality is governed by the same default duty and the same closed list of permitted disclosures taught with confidentiality and its limits in these notes; the remote setting does not create a fresh licence to disclose, but it multiplies the ways confidentiality can leak - an unsecured platform, a household member off-camera, a session recorded without consent, records held on a personal device. The **standard of care** is the anchoring construct: it is set by what a reasonable psychiatrist would do, and it does not fall because the encounter is remote.

OBLIGATION	IN-PERSON CONSULTATION	TELEPSYCHIATRY CONSULTATION
Consent	To assessment and treatment	Also to the remote modality and its limits
Standard of care	Reasonable clinical practice	The same standard, or refer to in-person care
Confidentiality	The room and the record	The platform, the setting at both ends, the stored data
Identity	Established directly; verified where required	Actively verified for patient and clinician
Emergency and risk	Managed in the room	Needs a pre-agreed local escalation plan

RULE **The medium changes the method, never the duty.** A remote consultation is held to the same standard of care, the same consent and the same confidentiality as a face-to-face one. Where the channel cannot support that standard for a given patient, the ethical answer is to convert to in-person care, not to lower the bar to fit the link.

TRAP **Believing the duties relax because the encounter is remote.** Candidates treat telepsychiatry as a lighter form of practice with softer obligations. The reverse is true: the same duties apply, and several - identity, confidentiality, emergency planning - actually demand more work to discharge at a distance.

13.4 When a remote encounter is not enough

Recognising the limits of the channel is itself an ethical duty, because persisting with an inadequate medium is a breach of the standard of care. Remote consultation is poorly suited, and often should give way to in-person assessment, in situations such as:

- acute suicidality or a patient who cannot be kept safe remotely;
- a first presentation of possible psychosis where insight and reality-testing must be examined directly;
- the need for a physical examination, an injectable, or supervised administration;
- a patient who cannot consent to or operate the technology, or lacks a private space;
- any encounter where identity, or the presence of a coercive third party off-camera, cannot be assured.

None of these forbids telepsychiatry outright; each demands a judgement that the remote channel can still deliver safe care, and a readiness to escalate to a physical review when it cannot.

13.5 Social media and public professionalism

A psychiatrist's conduct online is a professional matter and not merely a private one: the duties of confidentiality, restraint in advertising and general professional conduct that the operative code imposes follow the doctor onto the screen. The newer Regulations go further and address the medium directly: at Regulation **20**, a practitioner's conduct on social, electronic and print media *shall follow* the prescribed **Social Media Guidelines**, a dedicated framework that stands notified but in abeyance with the rest of that code. That provision is the codified form of what is better called **digital professionalism**: the recognition that a doctor carries the profession's standards into every public post. The recurring failures are specific to psychiatry. Confidentiality is breached by a case detail vivid enough to identify a patient even when the name is withheld. Boundaries erode when a treating psychiatrist accepts a patient's friend request or drifts into personal messaging, blurring the therapeutic frame that the work depends on. And the reach of a post multiplies both harms: an indiscretion that a corridor would swallow can travel to thousands. The corrective is to treat every public communication as though a patient, a colleague and a regulator will all read it, because any of them may.

GOOD TO REMEMBER

Keep one clear line between a professional presence and a personal account, and never take a treating relationship into either. Do not accept patients into your private social networks, do not discuss identifiable cases even in disguised form, and assume any post is permanent and public. If you use messaging for clinical contact, agree its scope with the patient and keep it inside the record, not on a personal phone.

13.6 Advertising, self-promotion and the boundary of legitimate announcement

The same conduct code that governs the consulting room governs how a psychiatrist may present a practice to the public, and here too the digital age has widened the temptation. The newer Regulations draw the line tightly: at Regulation **11** a practitioner may make only limited formal announcements - the starting, change or resumption of practice, a change of address, and a declaration of charges - and an institutional advertisement may not carry more than the name, the type of patients treated, the staff, the facilities and the fees. Everything beyond that factual minimum, particularly the soliciting of patients or the claiming of superiority, falls outside what an announcement may contain. The principle is old and survives the change of medium: a doctor informs the public of a service, and does not tout for custom. A polished website, a sponsored post or a testimonial reel is subject to the same restraint as a newspaper notice once was.

PITFALL

The commonest real-world error on this topic is citing the newer National Medical Commission Registered Medical Practitioner (Professional Conduct) Regulations as the operative code. They came into force on publication and were then held in abeyance, so a clinician who governs their advertising, telemedicine or social-media conduct by them alone is following rules that are not currently in force. The live code remains the Medical Council of India professional-conduct code, taught with the professional-conduct codes in these notes; read the newer provisions for substance but comply with the code that is actually operative.

Whatever the channel - a video link, a public post or an advertisement - the psychiatrist owes the same duty of care, confidentiality and honesty, and the currently operative code is the Medical Council of India professional-conduct code, not the newer Regulations still held in abeyance.

Disaster, prisoners and forensic special topics

14 · Disaster Management Act 2005 (psychiatric relevance)

A disaster statute earns its place on a forensic syllabus because it is administrative law the psychiatrist has to work inside, not around. Mass-casualty events - floods, earthquakes, industrial and transport accidents, epidemics - produce a predictable surge of acute stress reactions, grief, sleep disturbance, exacerbation of pre-existing illness and, in a minority, persistent post-traumatic and depressive morbidity. The clinician who wants to deliver care in that setting does not command the response; a statutory authority does. The examinable content is deliberately narrow: the architecture the Act builds, who heads each level of it, what the Act says disaster management is, and - the point most candidates miss - what it conspicuously does not say. Get those, and you can locate the psychiatric role precisely; miss them, and you will keep looking for a legal mandate the statute never wrote down.

Teach this as what it is: a piece of administrative machinery. The Act does not create clinical duties, define capacity, or authorise treatment; those belong to the mental-health statute and are developed in the Mental health legislation and forensic psychiatry notes. What it does is build a chain of authority from the national government down to the individual district, and then define the process those authorities are to run. The psychiatric role has to be read into that structure, because the structure will not hand it over.

14.1 A tiered command structure, not a clinical statute

The Act builds authorities at successive levels of government. It constructs a vertical chain: a national authority at the apex, a mirror authority in every State, and an operational authority in every district. Each is headed **ex officio** by the executive of its level, which is the deliberate design point - disaster response is treated as a whole-of-government function commanded from the top of government rather than by a technical body advising from the sidelines. At the

national and State tiers that head is the elected political executive; at the district tier it is the administrative executive - the Collector, District Magistrate or Deputy Commissioner - sitting alongside an elected local-authority co-chairperson. The comparison below fixes the section, the head and the establishing duty for each level; commit the section numbers, because a report or an answer that misplaces them signals unfamiliarity with the primary Act.

LEVEL	STATUTORY SECTION	CHAIRPERSON, EX OFFICIO	THE ESTABLISHING DUTY
National (apex)	section **3**	the Prime Minister	an authority shall be established for the purposes of the Act
State	section **14**	the Chief Minister of the State	every State Government shall establish an authority for the State
District	section **25**	the Collector, District Magistrate or Deputy Commissioner (co-chaired by the elected local-authority representative)	every State Government shall establish an authority for every district

The chain of authority the Act creates. Note that the head of each level is fixed by office, not appointed for expertise, and that the duty to establish the State and district authorities is mandatory and lies with the State Government.

Read the establishing duties for the modal verb, because it is examinable. At every level the statute is mandatory: the national authority *shall be established*, and every State Government *shall establish* both its State authority and a district authority for every district. There is no discretion in whether the machinery exists. What the Act leaves open is operational - how each authority discharges its functions - not whether it comes into being.

14.2 The apex and the State tiers

The national authority sets the policy floor. At the top the Act establishes the **National Disaster Management Authority**, under the establishment section set out above, chaired ex officio by the Prime Minister with not more than **nine** other nominated members. As the apex body its work is national in scope: it is the source of country-wide policy, plans and guidance, which is exactly why any national statement on how mental-health and psychosocial needs are to be met in disasters is issued from this level rather than written into the parent Act. Hold that distinction, because it explains where the mental-health content actually lives - in guidance under the machinery, not in the sections that build it.

The State authority mirrors the apex. One level down, the Act requires each State to constitute a **State Disaster Management Authority**, under its State-tier section, chaired ex officio by the Chief Minister. Its role is to translate national policy into a State plan and to coordinate the State's departments - health among them - so that a directive from the apex becomes a deliverable service on the ground. For the psychiatrist this is the tier at which mental-health

services are meant to be built into the State's disaster health response, alongside the rest of the health system.

14.3 The district tier, and why it is the one you will meet

This is where response actually happens. The **District Disaster Management Authority**, established under the Act's district-tier section, is the operational cutting edge of the whole structure - the level closest to survivors and the one that runs relief, rescue and coordination on the affected ground. Its chairperson is fixed by office: the Collector, District Magistrate or Deputy Commissioner heads it ex officio, and, distinctively at this level, the elected local-authority representative sits as ex officio co-chairperson, pairing the administrative head with local political representation. A clinician deployed into a disaster response is, in practice, working within this district authority's plan and under the district administration's coordination, not answering directly to the State or national bodies.

MNEMONIC

Prime Minister for the nation, Chief Minister for the State, Collector for the district

The head of each authority is the political or administrative executive of its own level, sitting by virtue of office rather than expertise. Only the district level adds a co-chairperson - the elected local-authority representative - which flags it as the tier where administration and local representation meet the survivor.

RULE **The Disaster Management Act is a chain of administrative authority, not a mental-health statute.** It mandates authorities at national, State and district level, each headed ex officio by the executive of that level, and defines the process they must run. It creates no clinical duty and names no psychiatric service, so the mental-health role must be located within its general functions, not read off an express provision.

14.4 What the Act means by disaster management - and its silence on mental health

The definition is broad, cyclical and process-oriented. The Act defines **disaster management**, at section **2(e)**, as a continuous and integrated process rather than a one-off emergency reaction. That process runs across the whole disaster cycle: preventing danger, mitigating risk and severity, building capacity, preparing to respond, mounting a prompt response, assessing the magnitude of effects, carrying out evacuation, rescue and relief, and finally rehabilitation and reconstruction. The pedagogical point is the shape: the statute conceives of management as spanning the time before, during and long after the event, which is precisely the time-course over which psychiatric morbidity emerges and recovers.

Now the omission that carries the marks. Read that definition again for what is absent. Nowhere in it does the Act name psychosocial or mental-health support as an express limb of disaster management. The functions it enumerates are physical and administrative - risk, rescue, relief, reconstruction - and the psychological dimension is simply not written in as a category of its own. This is not a drafting accident to be corrected in an answer; it is the settled position of

the primary text, and the honest teaching is to state it plainly and then show where the mental-health role has to be fitted instead: inside **capacity-building**, preparedness, response and rehabilitation, each of which can carry a psychosocial component even though none is labelled as such.

> **PITFALL**
> Assuming the Act itself contains an express psychosocial or mental-health provision, and then waiting for a statutory mandate that does not exist. Because national guidance on psychosocial support and mental-health services in disasters does exist, it is easy to project that content back onto the parent Act. It is not there. The clinician who understands this does not wait to be named in a section; they embed mental-health care within capacity-building, preparedness and rehabilitation, which is where the general functions leave room for it.

14.5 Locating the psychiatric role within the machinery

The role is real even though the statute is silent. The absence of a named limb does not make mental health optional; it makes it the clinician's job to insert it into the general process the Act defines. Disaster mental-health work maps onto that same cycle. Across it, the psychiatrist's contributions cluster into a few recognisable tasks:

- before the event - training first responders and building local capacity, so that psychological needs are anticipated rather than discovered;
- in the acute phase - **psychological first aid** and the triage of acute distress, distinguishing normal acute reactions from those needing active intervention;
- in relief and rehabilitation - continuity of treatment for people with severe mental illness whose medication and follow-up have been interrupted, and detection of the delayed post-traumatic and depressive morbidity that surfaces weeks to months later.

Continuity of care is the quiet emergency. The most avoidable harm in a disaster is not the new-onset disorder but the interruption of existing treatment: a person already stabilised on psychotropic medication who loses their supply, their prescriber and their records when services collapse. Restoring that continuity, and where necessary arranging care under the ordinary mental-health law, is squarely within the response and relief functions of the district authority, and the legal framework for such care sits in the Mental health legislation and forensic psychiatry notes, not in this Act. The disaster statute tells you which authority coordinates the response; the mental-health statute tells you how care may lawfully be given.

Equity is the ethical hinge. Disaster settings force allocation decisions - whose distress is attended to first when the need vastly exceeds the resource - and the principle of justice in the fair distribution of scarce care is the frame the psychiatrist brings to that. The principles of biomedical ethics are developed elsewhere in this chapter and are invoked, not re-listed, here; what matters for this topic is that the machinery gives you the coordinating authority, and the ethics gives you the priority rule for working within it.

IN INDIA

Because the definition of disaster management names no psychosocial limb, mental-health and psychosocial support in Indian disasters is delivered through guidance issued under the national authority and operationalised down the chain to the district level, rather than through an express section of the Act. In practice the clinician interfaces with the district authority under the Collector or District Magistrate, whose plan coordinates the response on the ground. Read the governing plan and the current national guidance from primary sources rather than from memory, because the Act itself will not point you to the mental-health role.

GOOD TO REMEMBER

If you are deployed, the authority you actually work within is the district one, headed by the Collector or District Magistrate, with the elected local representative as co-chair. That is where you register your service, plug into the coordinated response, and locate mental-health care inside the relief, response and rehabilitation functions. Do not wait for a statutory instruction naming psychiatry; the Act does not give one, and the role is yours to insert.

TRAP **Misassigning the heads of the three authorities.** The apex authority is chaired by the Prime Minister, the State authority by the Chief Minister, and the district authority by the Collector, District Magistrate or Deputy Commissioner, with the elected local-authority representative as co-chairperson. Candidates lose the mark by handing the State authority to the Governor or the district authority to the Superintendent of Police; each head is fixed by office at its own level, and only the district tier carries a co-chair.

3	14	25	2(e)
SECTION ESTABLISHING THE NATIONAL AUTHORITY, CHAIRED BY THE PRIME MINISTER	SECTION REQUIRING A STATE AUTHORITY, CHAIRED BY THE CHIEF MINISTER	SECTION REQUIRING A DISTRICT AUTHORITY, CHAIRED BY THE COLLECTOR	THE DEFINITION OF DISASTER MANAGEMENT

The Disaster Management Act builds authorities at national, State and district level, each headed ex officio - by the Prime Minister, the Chief Minister and the Collector or District Magistrate respectively, the district tier alone carrying an elected co-chairperson. Its definition of disaster management spans the whole cycle from prevention to reconstruction but names no psychosocial or mental-health limb, so the psychiatric role must be located within the general functions of capacity-building, preparedness, response and rehabilitation.

15 · Mental health of prisoners and forensic psychiatry services

Where this topic sits. A prison gathers, into one closed population, almost every risk factor a psychiatrist studies separately: poverty, substance use, head injury, trauma, social exclusion and untreated illness. It then strips away most of what protects mental health. The predictable result is that psychiatric morbidity in custody runs far above the community rate, while the services meant to answer it are thinnest exactly where the need is greatest. This topic asks two linked

questions: what is the mental health of prisoners, and what services, inside the prison and across the wider **forensic psychiatry** system, meet it.

What earns the marks here is not a table of prevalence figures but a service architecture and the single principle that organises it. You are expected to describe how psychiatric care actually reaches a prisoner, to place the Indian statutory backdrop correctly, and to keep a forensic psychiatry service distinct from the medico-legal assessments taught in neighbouring topics. The route by which a mentally ill prisoner is transferred into hospital care is developed in the companion account of the transfer and treatment of mentally ill prisoners, and the dignity and rights framing in the account of human rights and ethical issues in custodial psychiatry; the focus here is the burden and the service response to it.

15.1 The burden: psychiatric morbidity is concentrated in custody

Prisoners carry a marked excess of mental disorder across the whole diagnostic range. Relative to an age-matched community sample, custodial populations show more psychotic illness, more mood and anxiety disorders, far more substance use disorder, a high load of personality disorder, and an over-representation of intellectual disability and acquired cognitive impairment. This is a compounded burden, not a single condition, which is why a prison mental health service cannot be built around one diagnosis. The excess is real, large and consistent across settings; the precise magnitudes vary by jurisdiction and instrument.

Two mechanisms produce the concentration, and a good answer names both. The first is selection: people with mental illness are over-represented among those who enter custody in the first place, through offending linked to untreated illness, homelessness, substance use and the criminalisation of the mentally ill when community care is absent. The second is the effect of custody itself. Juvenile detainees sit under an entirely separate statutory framework and are dealt with in the Child psychiatry: assessment, treatment, services and protection notes; the clinical management of substance withdrawal and dependence in custodial settings belongs to the Substance use disorders notes. Both are named here, not taught.

15.2 Importation and deprivation: why prison generates and worsens disorder

The environment is part of the formulation. The excess morbidity is usually understood through two complementary models. The **importation** model holds that prisoners bring pre-existing vulnerability in with them: prior illness, developmental adversity, substance use and low social capital. The **deprivation** model holds that the custodial environment itself is pathogenic, independent of what a person arrives with. Neither model alone is sufficient; they operate together, and the clinical implication is that a prisoner's disorder cannot be treated as if it were context-free.

The deprivations of custody are specific and psychologically active. Loss of liberty and autonomy, overcrowding, enforced idleness, the threat of violence and bullying, separation from family and children, uncertainty about the future, and the collapse of privacy together constitute a chronic stressor field. Solitary confinement is the most concentrated form and is associated with acute deterioration, self-harm and psychotic phenomena. Because these are environmental

drivers, part of the treatment is sometimes environmental: relocation, occupation, family contact and the removal from isolation, alongside conventional psychiatric care.

15.3 The Indian statutory backdrop: the Prisons Act and its silence

Prison administration in India is still substantially governed by a colonial-era statute, and its treatment of mentally ill prisoners is notable for an absence. The Prisons Act of **1894** contains no substantive stand-alone section devoted to the care of mentally ill prisoners. The only hook is the State Government's rule-making power at section **59**, which at clause **(23)** authorises rules for the treatment, transfer and disposal of criminal lunatics or recovered criminal lunatics confined in prisons. Read the provision precisely: it is a discretionary power under which the State Government *may* make rules, not a substantive duty of care, and it uses the archaic term **criminal lunatic** that both modern law and clinical practice have long abandoned.

The lesson is structural: the primary prison statute does not itself build a mental health service or confer a right to treatment; it merely enables subordinate rules. The substantive machinery for actually moving a mentally ill prisoner into psychiatric care sits elsewhere, combining the older warrant power for removal with the mental-health statute's prisoner-specific provision, and is developed in the companion account of the transfer and treatment of mentally ill prisoners; the general mental-health law machinery belongs to the Mental health legislation and forensic psychiatry notes. That historical silence is why India's prison mental health provision has depended on the later statute, on prison manuals and on the courts rather than on the parent Act.

IN INDIA

The governing prison statute is over a century old and, on mental health, gives only a rule-making power rather than a service. The practical consequence is that a mentally ill prisoner's care depends on the mental-health law, on State prison manuals, and on directions issued by the constitutional courts, rather than on any express care provision in the Prisons Act. When answering, place the substantive rights and transfer route in the mental-health statute and treat the Prisons Act as the historical backdrop, citing the primary Act and clause rather than a remembered figure.

PITFALL

Reading the Prisons Act rule-making power as if it were a substantive care regime, and then treating a mentally ill prisoner's admission or transfer as a matter of prison rules. The enabling clause lets the State make rules; it does not itself authorise clinical care or lawful transfer. The care standard and the transfer route are set by the mental-health law, not by that rule-making power, and a clinician who looks only to the prison statute will not find the authority they need.

15.4 The architecture of forensic psychiatry services

A forensic service is a pathway, not a place. Forensic psychiatry is the subspecialty concerned with the assessment, treatment and risk management of the **mentally disordered offender** and with the interface between psychiatry and the courts. A mature forensic service is not a single

ward but a tiered system that meets the offender at each point of the criminal-justice pathway, from first contact with the police through to eventual return to the community.

SERVICE COMPONENT	WHERE IT OPERATES	PRIMARY FUNCTION
Court liaison and diversion	police station and courts	identify mentally disordered defendants at the earliest point and divert them to health care rather than custody where that is appropriate
Prison in-reach	within the prison	bring specialist mental health assessment and treatment to prisoners in situ, functioning as the prison's equivalent of a community mental health team
Secure forensic inpatient unit	dedicated secure hospital (graded levels of security)	treat offenders who need hospital-level care under conditions of physical, procedural and relational security
Forensic rehabilitation and community forensic team	step-down and community	rehabilitate, supervise and manage risk as the offender transitions out of secure care

The tiers of a forensic psychiatry service, arranged along the offender's pathway. Each tier answers a different need; a system missing any one tier tends to silt up at the level below it, most visibly when the absence of secure beds strands seriously ill offenders in the prison.

The tiers depend on one another. Diversion works only if there is somewhere to divert to; in-reach can identify a prisoner who needs hospital care but cannot deliver it without secure beds; and secure units block if no rehabilitation tier receives their recovered patients. This is why forensic planning is done as a whole system, and why the commonest failure is a bottleneck rather than an absent service.

RULE **Prisoners are entitled to the same standard of health care as the general community.** This is the principle of **equivalence of care**, and it is the organising rule for every prison and forensic mental health service: the fact of imprisonment removes liberty, not the right to health care. It sets the benchmark against which a custodial service is judged, and it is the reason care that would be routine in the community cannot be rationed away simply because the patient is a prisoner. The broader dignity and rights framing is developed in the account of human rights and ethical issues in custodial psychiatry.

15.5 Mental health services within the prison: screening, in-reach and continuity

The service inside the wall begins at the gate. The single most important service element is **reception screening**: a structured assessment at the point of entry, because the early days of custody are the highest-risk window for both crisis and undetected illness. It is not a formality; it is how a service finds the people it must treat before they deteriorate. Its aims are:

- to detect existing serious mental illness and any current treatment that must be continued without interruption;

- to identify acute suicide and self-harm risk in the first, most dangerous nights of custody;
- to flag substance intoxication or impending withdrawal for management under the appropriate protocol;
- to recognise intellectual disability and cognitive impairment that will shape how the prisoner copes and is managed.

From screening, a referral pathway feeds the prison's tiered response: primary mental health care delivered on the wing, specialist in-reach assessment for those who need it, and onward referral for the minority who require hospital-level care, the transfer route covered in the companion account. The quiet failure of prison mental health is discontinuity: care interrupted at the point of entry, or dropped at the point of release, when a person leaves custody without a prescription, a follow-up appointment or a receiving service. Release is a period of markedly elevated relapse and mortality risk.

GOOD TO REMEMBER

Screen at reception and act on it, rather than waiting for breakdown. The prisoners who die or deteriorate are disproportionately those missed in the first days, and the two decisions that change outcomes are continuing established treatment without a gap on the way in, and arranging a warm handover to a community service on the way out. Build the pathway around those two transitions.

15.6 Suicide, self-harm and the crisis end of custodial care

This is where the service is tested hardest. Suicide and self-harm are the sentinel outcomes of a custodial mental health system, and a disproportionate share occurs early in custody, in remand and in the first period after reception, when uncertainty, withdrawal and the shock of imprisonment converge. A credible service therefore runs a suicide-prevention system rather than relying on individual vigilance: identification at reception and at points of change, safer environments, graded observation for those at acute risk, peer support, staff training to recognise and escalate concern, and structured review after every serious incident so the system learns. This is where equivalence of care stops being abstract: the community standard for a person in suicidal crisis is active, urgent intervention, and custody must meet it.

TRAP **Confusing a forensic psychiatry service with the assessment of criminal responsibility.** The service exists to assess, treat and rehabilitate mentally disordered offenders and to run mental health care in prisons; it operates whether or not any insanity defence is ever raised. The criminal-responsibility doctrine, the insanity-defence test and the fitness-to-stand-trial criteria are a separate matter, taught in the Mental health legislation and forensic psychiatry notes. Candidates lose marks by collapsing the whole of forensic psychiatry into the courtroom question of responsibility, when the great majority of forensic clinical work is service delivery to offenders who are simply unwell.

1894	59	(23)
THE PRISONS ACT STILL FORMING THE BACKDROP TO PRISON ADMINISTRATION	ITS SOLE MENTAL-HEALTH HOOK, THE STATE RULE-MAKING POWER	THE CLAUSE ON TREATMENT, TRANSFER AND DISPOSAL OF CRIMINAL LUNATICS

Prisoners carry a large excess of mental disorder, driven together by importation of pre-existing vulnerability and by the deprivations of custody, and are entitled by the principle of equivalence of care to the same standard of mental health care as the community. In India the Prisons Act of 1894 creates no substantive care provision, only a State rule-making power over criminal lunatics, so the substantive care and transfer machinery lives in the mental-health law and the older warrant power it rests on, not in the Prisons Act; the forensic response is a tiered service running from court diversion through prison in-reach and secure inpatient care to community rehabilitation, anchored at reception screening and at the crisis prevention of suicide and self-harm.

16 · Transfer and treatment of mentally ill prisoners

A term of imprisonment does not suspend a person's mental illness, and the law has to answer a plainly administrative question - on whose authority, and to which bed, is a prisoner who is or becomes mentally ill moved for treatment. The examinable content here is narrow but exact, and the marks reward a candidate who can name the operative provision, state the order of preference it lays down, and keep its mandatory language distinct from the older discretionary power it rests upon. Get the sequence wrong, or soften a "shall" into a "may", and you have described a different rule from the one the statute actually enacts.

This account owns the transfer-and-treatment route only. The wider structure of mental health services inside prisons and the forensic psychiatry service belongs to this chapter's account of the mental health of prisoners and forensic psychiatry services and is named here, not rebuilt; the rights lens - dignity, least restriction, non-discrimination in custody - belongs to this chapter's account of human rights and ethical issues in custodial psychiatry. The general machinery of the Act, its definitions, the review board's constitution and powers, capacity and admission, is taught in the Mental health legislation and forensic psychiatry notes; the prisoner-specific transfer provision is what is grounded and taught in full below.

103	2017	30	1900
MENTAL HEALTHCARE ACT SECTION FOR PRISONERS WITH MENTAL ILLNESS	THE MENTAL HEALTHCARE ACT NOW IN FORCE	PRISONERS ACT SECTION IT CROSS-REFERS TO	THE OLDER ACT THAT PROVISION SITS IN

16.1 The provision that supplies the authority

The governing provision is the Mental Healthcare Act, 2017, at section **103**, and its first job is to solve a purely legal problem: what document is enough to lawfully admit a **prisoner with mental illness** into an establishment for care. The answer the section gives is that an order directing such admission, made under any of a specified set of Acts, is by itself enough. Among those specified sources is section **30** of the Prisoners Act, 1900, alongside orders made under the armed-forces Acts and under the criminal procedure law.

The operative words are that such an order "shall be sufficient authority" for admitting the person to the establishment to which they may lawfully be transferred for care and treatment. That

modal verb is the whole point. The section does not create a fresh discretion to be exercised at the prison gate; it declares that a validly made order already carries the legal weight needed, so the receiving establishment need not look behind it for some further sanction. This is **sufficient authority** in the technical sense - a completed legal warrant, not an invitation to reassess.

16.2 The first door: the prison's own psychiatric ward

Having settled authority, the section settles destination, and it does so with an order of preference that is the single most tested feature of the whole topic. The first proviso states that transfer of a prisoner with mental illness to the **psychiatric ward in the medical wing of the prison** shall be sufficient to meet the requirements of the section. In other words, the default and preferred response is to treat the prisoner inside the prison, in a dedicated psychiatric ward, rather than to move them out of custody into an external hospital.

The reasoning behind this preference matters for the answer, not only for practice. Keeping treatment within the prison medical wing avoids the security and continuity problems of moving a prisoner to and from an outside facility, keeps the person within a single accountable custodial system, and reflects the Act's commitment to the least disruptive appropriate setting. The examiner is testing whether you know that the in-prison ward is the statutory first line, because the intuitive answer - send the mentally ill prisoner to a mental hospital - is the second line, not the first.

16.3 The second door, the Board's permission, and the continuing safeguards

The second proviso supplies the fallback and hedges it with a condition. Where there is no provision for a psychiatric ward in the medical wing, the prisoner may be transferred to a **mental health establishment** with the prior permission of **the Board**. Two elements have to be stated together for the mark. First, the external transfer is contingent - it becomes available only when the in-prison ward does not exist, not as a free alternative. Second, it is gated: it requires the Board's permission in advance, not a post-hoc ratification. The review board itself, how it is constituted and what else it does, is a matter for the Mental health legislation and forensic psychiatry notes; here it functions as the authorising gate on the out-of-prison route.

The section does not stop at the moment of transfer. It builds in continuing oversight so that a prisoner moved for mental illness is not simply lost inside the system, and these duties are worth listing because a "state the safeguards" question turns on them:

- a quarterly reporting duty on the prison medical officer;
- powers of visitation exercisable by the Board;
- special reports at six-monthly intervals, giving a fixed rhythm of scrutiny beyond the routine quarterly report;
- a duty on the appropriate Government to establish a mental health establishment in the medical wing of at least **one** prison in each State and Union Territory, so that the preferred in-prison route is actually available and does not collapse into the external transfer for want of a ward.

That last duty is the structural safeguard behind the whole preference: the first-line option only means something if a psychiatric ward physically exists to receive the prisoner, so the statute obliges the Government to build the capacity its own order of preference assumes.

RULE **An order directing admission of a prisoner with mental illness is itself sufficient authority; the first option is the psychiatric ward in the prison's medical wing, and only where no such ward exists may the prisoner be transferred to a mental health establishment, and then only with the Board's prior permission.** The sequence is fixed and conditional, not a menu. Sufficiency of authority is declared in mandatory terms; the in-prison ward "shall be sufficient" to meet the section; the external transfer is the exception, unlocked by the absence of a ward and licensed by the Board in advance. Collapsing this to "a mentally ill prisoner is sent to a mental health establishment" states the fallback as if it were the rule.

16.4 The older statute the section rests on: the Prisoners Act warrant

Section **30** of the Prisoners Act, 1900, is the provision the current section expressly cross-refers to, and it is the historical engine that produces the very "order directing admission" the modern Act then treats as sufficient. Its language is of its era and should be read as such, but its structure is still live. Where it appears to the State Government that a person detained or imprisoned under any order or sentence of a court is of unsound mind, the State Government may, by a **warrant** setting out the grounds of that belief, order the person's removal to a lunatic asylum or other **place of safe custody** within the State, there to be kept and treated as the Government directs for the remainder of the term of detention or sentence.

Two features carry the marks. The power is discretionary - "may, by a warrant" - and it is exercised by the State Government on a stated belief of unsound mind, with the grounds recorded in the warrant itself, which is the accountability check built into an otherwise wide power. And it contains a continuation clause that reaches beyond the sentence: if, on the expiry of the term, a medical officer certifies that further detention under medical care or treatment is necessary for the safety of the prisoner or of others, the person may be kept until discharged according to law. That is how a person can lawfully remain in medical custody after the original sentence has run - not on the executive's say-so alone, but on a medical certification of necessity tied to safety.

16.5 Reading the two provisions together

The clean way to hold this is as one modern authority-and-destination rule sitting on top of an older warrant power. The Prisoners Act warrant produces the order; the Mental Healthcare Act declares that order sufficient and then dictates where the prisoner should go, ward first, external establishment only by exception. Keeping the two verbs straight - the discretionary "may" of the warrant, the declaratory "shall be sufficient" of the modern authority - is what separates a precise answer from an approximate one. The grid sets the contrast out.

AXIS	PRISONERS ACT WARRANT	MENTAL HEALTHCARE ACT PROVISION
FUNCTION	Creates the power to remove a prisoner of unsound mind	Declares an admission order sufficient authority and fixes the destination
WHO ACTS	The State Government, by warrant recording its grounds	The prison system, under the order, subject to the Board for external transfer
MODAL CHARACTER	Discretionary: "may, by a warrant" order removal	Mandatory/declaratory: the order "shall be sufficient authority"
DESTINATION	A lunatic asylum or other place of safe custody within the State	First the prison's psychiatric ward; an external establishment only if no ward exists, with the Board's prior permission
DURATION	Remainder of the term, and beyond it if a medical officer certifies continued detention necessary for safety	Governed by the originating order and applicable law, with quarterly and six-monthly reporting and Board oversight

TRAP **Stating external transfer to a mental health establishment as the standard response for a mentally ill prisoner.** Candidates recall that the prisoner is "sent for treatment" and name the outside hospital, missing that the section makes the psychiatric ward in the prison's own medical wing the first option and treats the external establishment as the exception - available only where no such ward exists, and only with the Board's prior permission. Answer with the order of preference, not with the fallback, because the fallback is the very thing the section is drafted to make secondary.

IN INDIA

This is an entirely Indian statutory scheme with no Western template to borrow. The current authority is the Mental Healthcare Act, 2017, which folded the prisoner provision into the same rights-based Act that governs civil admission, while expressly preserving the older removal power in the Prisoners Act, 1900. The practical gap the Act tries to close is the historical shortage of in-prison psychiatric wards, which is precisely why it lays a duty on the appropriate Government to build a mental health establishment in the medical wing of at least one prison per State and Union Territory.

GOOD TO REMEMBER

When advising on a prisoner who has become mentally ill, look first to the prison's own psychiatric ward, because that is the statutory first line, and reserve transfer to an outside establishment for where no such ward exists - flagging that the external move needs the Board's prior permission before it happens, not after. If care will be needed beyond the end of the sentence, the lawful route to continuation is a medical officer's certification that further detention is necessary for the safety of the person or of others, which is what turns the end of a sentence into grounded continued care rather than unlawful detention.

PITFALL

The section cross-refers to orders made under the criminal procedure law, and those references are to the provisions of the 1973 Code as they stood when the Act was passed. Since the criminal statutes changed on the first of July 2024, an author who cites the old procedural sections as current is quoting a superseded code; the savings position and the current successor provisions are treated in this chapter's account of the current penal-code framework and its transition to the new criminal codes, and should be cross-referred rather than restated here. Name the transfer authority from the Mental Healthcare Act and the Prisoners Act, which are grounded, and do not attach a procedural section number from memory.

An order directing admission of a prisoner with mental illness is sufficient authority under the Mental Healthcare Act, 2017; the first option is the psychiatric ward in the prison's medical wing, and only where no such ward exists may the prisoner be transferred to a mental health establishment, and then only with the Board's prior permission - the power to remove being drawn from the discretionary warrant of the Prisoners Act, 1900.

17 · Human rights and ethical issues in custodial psychiatry

A person does not surrender the right to health, to dignity or to protection from cruelty at the prison gate. Custodial psychiatry is where the ordinary ethics of the profession meet the extraordinary fact that the patient cannot walk away and often cannot freely refuse. The setting concentrates every rights problem the discipline has: liberty is already removed, the environment is coercive, the clinician answers to an institution as well as to the patient, and the people most affected are among the least able to assert a claim for themselves. The marks here are for the rights-and-ethics lens itself, not for the plumbing of prison mental health, and an examiner rewards the candidate who can name the rights at stake, the Indian authority that protects them and the ethical trap the custodial role sets.

- Dignity
- Equivalent care
- Confidentiality
- Protection from cruelty
- Clinical independence
- Dual loyalty

Fig 26.10 A person in custody retains the rights to dignity, health care and protection from cruel or degrading treatment. The psychiatrist must preserve clinical independence and confidentiality while recognising the dual-loyalty pressures created by the institution.

What this topic owns is that lens. The structure of mental health services for prisoners belongs to this chapter's account of the mental health of prisoners and forensic psychiatry services, and the pathway for moving and treating a mentally ill prisoner belongs to this chapter's account of the transfer and treatment of mentally ill prisoners; both are named here and cross-referred, not reworked. The ethical frame for coercion and restraint in general is developed in this chapter's account of the ethical issues in involuntary treatment, restraint and end-of-life care, and its legal frame in the account of the legal aspects of seclusion, restraint and involuntary treatment. The clinical management of drug and alcohol problems in custody sits in the Substance use disorders notes.

17 Aug 1993	3 Oct 1994	19 Jun 2023
SUPREME COURT BARRED JAILING THE NON-CRIMINAL MENTALLY ILL	THE FOLLOW-UP ORDER ENFORCING THAT BAR	NHRC ADVISORY ON CUSTODIAL SELF-HARM AND SUICIDE

17.1 The rights lens: dual loyalty and the equivalence of care

Two ideas organise the whole topic. The first is the psychiatrist's problem of **dual loyalty**: a clinician working inside a custodial system owes the ordinary fiduciary duty to the patient in front of them, but the institution that pays and permits them wants order, security and compliance, and those two pulls do not always point the same way. A request to certify a prisoner fit for punishment, to medicate a difficult inmate for the convenience of the wing, or to disclose clinical information to custodial staff for reasons that are not the patient's, are all moments where loyalty to the patient and loyalty to the institution collide. The rights lens resolves the collision in one direction: the clinical relationship, and the patient's rights within it, come first, and the doctor's role is never to be an instrument of punishment or control dressed as treatment.

The second idea is the principle of **equivalence of care**: a person deprived of liberty is entitled to a standard of health care equivalent to what is available in the community, without discrimination on the ground of their legal status. Detention removes freedom of movement; it is not a sentence to worse medicine. Because the detained person cannot seek a second opinion, cannot easily complain and cannot leave, equivalence is a corrective for a captive population's structural disadvantage. Taken together, dual loyalty tells the clinician whom they serve, and equivalence tells them to what standard.

RULE **Loss of liberty is not loss of the right to health, to dignity or to consent; care in custody must be equivalent to care in the community and must never become an instrument of the institution against the patient.** Every specific rule that follows, the bar on jailing the non-criminal ill, the duty to screen, the limits on coercion, is an application of this one sentence. When a custodial question puzzles you, return to it: what would this person be owed outside, and what is the least the institution may do to them inside.

17.2 Sheela Barse: the non-criminal mentally ill do not belong in jail

The single most examinable Indian authority in this area is the **Sheela Barse** litigation, in which the Supreme Court confronted the practice of holding mentally ill persons who had committed no offence in ordinary jails, frequently under the label of "safe" or protective custody, for want of anywhere else to put them. By its judgment dated **17 August 1993** the Court strictly prohibited the confinement of non-criminal mentally ill persons in jails. The prohibition was not advisory and not conditional: a person whose only "offence" is their illness may not be warehoused in a penal institution, because a jail is a place of punishment and this person is not being punished.

The force of the ruling lies in how the Court framed the wrong. Confining the non-criminal mentally ill in jail was treated as a violation of their constitutional rights, and therefore as a matter attracting the Court's compensatory jurisdiction: not merely bad administration but an actionable breach for which the State could be held answerable. That the point had to be restated is itself the lesson: by the follow-up order dated **3 October 1994** the Court recorded its dismay that the earlier prohibition was still not understood, and reiterated it. For the exam, the case stands for a clean proposition: illness is not criminality, and the response to a person found wandering and unwell is care in a health facility, never a cell.

TRAP **Treating "protective" or "safe" custody of the non-criminal mentally ill as a benign holding measure.** Candidates soften the Sheela Barse bar into a matter of resources, reasoning that a jail is acceptable when no hospital bed is free. It is not: the prohibition on confining the non-criminal mentally ill in jail is a rights bar, not a preference, and the absence of an alternative is the State's problem to solve, not a defence to the wrong. The correct answer is always diversion to a health facility, and the pathway for a prisoner who does need psychiatric care sits in this chapter's account of the transfer and treatment of mentally ill prisoners.

17.3 Custodial self-harm and suicide: the duty to look

Suicide and deliberate self-harm are the sharpest rights problem inside the wall, because the State that has taken a person into its exclusive control has assumed a corresponding duty to keep them alive, and a custodial death raises at once the questions of what was known and what was done. The population is high-risk by construction: the shock of first reception, withdrawal from substances, isolation from family, the loss of autonomy and the concentration of untreated mental illness make the early days of custody especially dangerous. A rights-respecting system therefore treats detection as an active duty rather than waiting for a prisoner to declare distress they may be least able to voice.

The Indian regulatory answer is captured in the National Human Rights Commission advisory dated **19 June 2023** on mitigating deliberate self-harm and suicide attempts by prisoners, which recommends, among other measures, that mental health screening be included in the initial health screening report of every prisoner and that prison staff be trained in **Psychological First Aid** and mental health literacy. Note the two moves. Screening at reception catches the risk when it is highest and before the system has lost sight of the person; training the frontline staff, who see prisoners far more than any clinician does, turns wing officers into the first line of recognition rather than bystanders. These are recommendations of a rights body, not a statutory command, but they set the standard of humane practice against which a custodial system's failures are now measured.

GOOD TO REMEMBER

When you assess anyone entering custody, screen for suicide risk as a routine part of the reception health check, not only when a threat is voiced. Document what you asked and what you found, and flag those at risk to the staff who will actually be watching them overnight. In a custodial death the contemporaneous reception note is the first thing scrutinised, and "no concerns raised" is not the same as "screened and none found".

17.4 Consent, confidentiality and coercion behind the wall

The everyday ethics of the encounter are distorted by the setting. Consent given in custody is suspect on its voluntariness: a person who believes that refusing treatment will affect their parole, their classification or their handling by staff is not consenting freely, so the clinician must work harder to separate a genuine choice from a coerced one. Confidentiality is under constant pressure, because custodial staff routinely want clinical information, yet the duty follows the patient into custody and is not waived by their status; disclosure to the institution is justified only on the same narrow grounds that would justify it outside. The elements of valid consent and the

permitted grounds for breaching confidence are taught in this chapter's own accounts of those topics and are applied here, not restated.

Coercive control is the third pressure, and custody offers instruments a hospital does not. The ways the setting erodes rights are worth holding as a list, because each is a distinct place a clinician can be co-opted:

- segregation imposed for order being passed off as therapeutic seclusion;
- medication used for the convenience of the regime rather than the patient's illness, so-called chemical restraint;
- solitary confinement of a mentally ill prisoner, which can itself cause or worsen psychiatric harm;
- clinical information fed to custodial or disciplinary processes without the patient's interest in view.

The general ethics of restraint and seclusion, and their legal safeguards, belong to this chapter's accounts of the ethics and of the legal aspects of seclusion, restraint and involuntary treatment; the statutory restraint machinery itself sits in the Mental health legislation and forensic psychiatry notes. What the rights lens adds is the reminder that in custody every one of these instruments is more available and less visible, so the clinician's refusal to lend clinical authority to punishment is the safeguard that matters most.

PITFALL

The commonest real-world error is accepting a prisoner's consent, or their apparent calm, at face value. A man who agrees to depot medication because he fears the consequences of refusal has not truly consented, and a prisoner segregated "for his own safety" may be deteriorating in isolation rather than being protected by it. Read voluntariness in the light of the coercive environment, and do not treat isolation of a mentally ill person as a neutral administrative fact: a person with mental illness shall not be subjected to seclusion or solitary confinement, so safety must be met through lawful alternatives rather than isolation.

17.5 Non-discrimination and the standard-setting frame

Underlying all of the above is the principle of **non-discrimination**: legal status is not a permissible ground for delivering worse care, and the detained mentally ill are entitled to the same rights and quality of treatment as any other patient. This is why equivalence of care is stated as a right and not an aspiration, and why the Sheela Barse bar and the NHRC's reception-screening recommendation are best read together, one keeping the wrong person out of the penal system entirely, the other protecting the right person once lawfully within it.

The topic also sits within a wider architecture of standards. International minimum standards for the treatment of prisoners and for the protection of persons with mental illness, and India's own disability-rights and mental-health statutes, all articulate versions of dignity, equivalence and non-discrimination in custody; the domestic statutory machinery is set out in the Mental health legislation and forensic psychiatry notes and is applied here rather than restated. For the

practising psychiatrist the message survives the detail: the rights of the person in custody are the rights of any patient, made more fragile by captivity and therefore owed more vigilance, not less.

RIGHT AT STAKE IN CUSTODY	HOW THE SETTING THREATENS IT	THE RIGHTS ANSWER
LIBERTY OF THE NON-CRIMINAL ILL	Held in jail as "protective" custody for want of a bed	Absolute bar on jailing them; divert to a health facility
LIFE (PROTECTION FROM SELF-HARM)	High-risk population, distress unvoiced, watch diffuse	Mental health screening at reception; trained frontline staff
VOLUNTARY CONSENT	Refusal feared to affect parole, classification or handling	Test voluntariness against the coercive environment
CONFIDENTIALITY	Staff demand clinical information; no private space	Duty follows the patient; disclose only on the usual narrow grounds
EQUAL STANDARD OF CARE	Legal status used to justify inferior treatment	Equivalence of care and non-discrimination

A person in custody keeps every health-related right they had outside, made more fragile by captivity and so owed more vigilance: care must be equivalent to the community standard and free of discrimination, the non-criminal mentally ill may not be confined in jail at all, self-harm and suicide risk should be actively screened at reception as the NHRC advises, and the psychiatrist's clinical authority must never become an instrument of the institution against the patient.

Forensic Indian statutes and legal procedure

18 · Sexual offences law and Criminal Law Amendment (rape, consent, psychiatric assessment of survivors)

The law changed its numbers, not the reader's duty to get them right. This topic is the criminal law of sexual offences as it now stands: the definition of rape and its punishment in the current penal code, the exact legal meaning of consent on which the offence turns, and the part a psychiatrist plays when a survivor is examined or when a court needs to know whether a complainant could consent. The marks cluster in three places, and each is one where confident memory of the old law is a liability. The first is currency: the provisions were re-enacted when the colonial-era penal code was replaced, so the section a report cites must be the live one. The second is a conceptual trap: the criminal law's "consent" is a different construct from the consent a clinician takes before treatment, and the two are examined together precisely so that candidates conflate them. The third is the narrow but genuinely psychiatric interface, the short list of conditions - unsoundness of mind, intoxication, an inability to communicate - in which whether there was consent at all becomes a question a psychiatrist is competent to address.

A psychiatrist who assesses a survivor, or who is asked to opine on capacity to consent, works entirely inside this statutory frame. The full account of how the penal code changed, and the savings rule that decides which code governs a given matter, belongs to this chapter's account of the current penal code and its predecessor, and is named here rather than re-derived; the task here is the sexual-offences provisions themselves and the clinician who stands beside them.

18.1 The reform lineage: from a committee's report to the current code

Why the modern definition looks the way it does. The shape of the present offence is the direct product of a single wave of reform. After the Delhi gang-rape case that provoked national reform, the **Justice Verma Committee** was convened, and its recommendations were substantially enacted as the **Criminal Law (Amendment) Act 2013**. That amendment did two things that still dominate the topic. It broadened the offence of rape well beyond the older, narrow idea of peno-vaginal intercourse, replacing it with a defined set of sexual acts, penetrative and oral; and it recast consent as something that must be affirmatively communicated rather than merely not refused. When the penal code was later rewritten, these post-2013 amendments were not reopened: the broadened definition and the affirmative-communication consent standard were carried forward substantively unchanged into the current code. For the examinee this continuity is a gift and a trap at once: the settled understanding of the amended offence survives intact, but the section numbers moved, so an answer written in the old citations describes the right law under the wrong name.

18.2 The offence defined: rape under the current penal code

An act, done in a defined circumstance. The offence of **rape** is defined in the current penal code, the **Bharatiya Nyaya Sanhita**, at section **63**, the successor to the repealed penal code's rape provision. Its architecture is two-part, and the discipline is to hold both parts together: a defined physical act, performed under one of a defined set of circumstances. The amendment carried into this section widened the physical act into **four** categories of sexual conduct: penile penetration of the vagina, mouth, urethra or anus; insertion of an object or a body part other than the penis; manipulation of a part of the body so as to cause penetration; and application of the mouth to the vagina, anus or urethra. The first three turn on penetration or insertion; the fourth is complete on the application of the mouth, without proof of penetration, and a candidate who calls all four penetrative has narrowed the section. None of these is an offence in the abstract; each becomes rape only when done in one of the listed circumstances.

The circumstances, and where the psychiatry lives. The circumstances that make an act rape are a closed statutory list, and they repay grouping rather than rote recall. They run:

- against the woman's will, or without her consent at all;
- with a consent extracted by putting her, or someone she cares about, in fear of death or of hurt;
- with her consent, where the man knows he is not her husband and she consents because she believes he is another man to whom she is, or believes herself to be, lawfully married;

- with a consent given when, by reason of unsoundness of mind, intoxication, or a stupefying or unwholesome substance, she is unable to understand the nature and consequences of that to which she consents;
- where she is below the age the section fixes, in which case her consent is immaterial; and
- where she is unable to communicate consent.

The fourth and the last of these are the psychiatric heartland of the whole topic. Whether a person could, at the material time, understand the nature and consequences of a sexual act, or could communicate a choice about it, is not a lay judgement; it is a capacity assessment, and it is the point at which a court is most likely to want a psychiatrist. The section itself, by writing unsoundness of mind and intoxication into the definition, makes the clinician's assessment part of the legal question rather than a bystander to it.

MNEMONIC

Mind, Substance, Speech

The three circumstances in the rape definition that turn on the complainant's capacity rather than on the surrounding facts: **M**ind (unsoundness of mind), **S**ubstance (intoxication or an administered stupefying or unwholesome substance), and **S**peech (an inability to communicate consent). Each may call for clinical expert evidence rather than lay judgement, and the cause decides which expert: intoxication may turn on toxicological evidence and an inability to communicate on neurological or physical evidence, while the psychiatrist speaks only to the psychiatric question. Where the cause is psychiatric, whether there was consent has become, in part, a question about capacity, and that is the clinician's territory.

18.3 The legal meaning of consent, and why it is not clinical consent

Consent defined by the section, not by the clinic. The definition the offence turns on is the criminal-law meaning of **consent**, set out in Explanation **2** to the rape section, and it is the single most examined line in the topic. Consent means an **unequivocal voluntary agreement**, in which the woman, by words, gestures, or any form of verbal or non-verbal communication, communicates willingness to participate in the specific sexual act. The definition then closes a door that the older law had left ajar: a woman who does not physically resist the act shall not, by reason only of that fact, be regarded as consenting. Two features are load-bearing. Consent is affirmative and communicated, not inferred from the absence of a "no"; and it is act-specific, so agreement to one thing is not agreement to another.

A different construct that shares a word. This is where candidates lose marks, because the clinical doctrine of informed consent, its elements of capacity, adequate disclosure and voluntariness, is taught in this chapter's account of informed consent in psychiatry, and the two doctrines overlap far less than the shared noun suggests. Both ask for voluntariness, and both attach to a specific act rather than to a general willingness, and there the resemblance stops. Clinical consent is a prospective authorisation a competent patient gives a clinician for an intervention, built on capacity and on disclosure of risks and alternatives; the criminal law's consent is a retrospective factual question about whether an unequivocal, communicated

willingness to a specific act existed at a particular moment. The comparison below fixes the contrast so it cannot be blurred under pressure.

AXIS	CLINICAL (INFORMED) CONSENT	CONSENT IN THE LAW OF SEXUAL OFFENCES
The question it answers	May this clinician proceed with this intervention?	Did an unequivocal, communicated willingness to this specific act exist?
Where it is defined	The general doctrine of informed consent (its own topic in this chapter)	The Explanation to the rape section of the current penal code
Its core standard	Capacity, adequate disclosure of information, and voluntariness	An unequivocal voluntary agreement, communicated by word, gesture or other means, to the specific act
Orientation in time	Prospective: an authorisation given before the act	Retrospective: a finding of fact about a past moment
Effect of silence or non-resistance	Silence is not authorisation; a positive agreement is required	Failure to physically resist is not, by that fact alone, consent
Whose interest it protects	The patient's autonomy over their own treatment	The complainant's sexual autonomy against a criminal wrong

Two constructs that share the word "consent" and, beyond voluntariness and an act-specific agreement, little else. A report that answers the clinical-capacity question when the court asked the criminal-law-consent question, or the reverse, has misread the brief before it has misread the facts.

RULE **Criminal-law consent is an unequivocal, communicated, act-specific willingness, and the absence of physical resistance is not consent.** The definition is affirmative and positive: it asks what the woman communicated, not what she failed to do. It is tied to the specific sexual act, so agreement to one act does not extend to another. And it stands apart from the clinical doctrine of informed consent, which is a prospective authorisation for treatment built on capacity and disclosure. The two are examined side by side so that they will be confused; the mark is in keeping them separate.

TRAP **Answering the criminal-law consent question with the clinical capacity-and-disclosure test.** Asked whether a complainant consented, the unwary candidate reaches for the informed-consent checklist - was there capacity, was there disclosure, was it voluntary - and imports a treatment doctrine into a criminal statute. The section does not ask whether a valid clinical authorisation was obtained; it asks whether an unequivocal, communicated willingness to the specific act existed, and it treats the absence of resistance as no answer at all. Capacity enters the criminal analysis only through the circumstances the section names, unsoundness of mind, intoxication and inability to communicate, not as a free-standing test.

18.4 The exceptions and the punishment

Two exceptions, each with its condition. The offence carries two carve-outs, and each must be stated with its condition or not at all. A medical procedure or intervention shall not constitute rape, which shields the clinician performing a lawful examination or treatment. Separately, intercourse or sexual acts by a man with his own wife are not rape, provided the wife is not below

the age the section fixes: the exception operates only at or above that age threshold, and where the wife is below it the exception does not apply. Naming the **marital-rape exception** without its age condition is how a candidate turns a precise carve-out into a wrong general statement.

Punishment. The punishment for rape is prescribed at the section that follows the definition, section **64**, the successor to the repealed penal code's punishment provision. An offender shall be punished with rigorous imprisonment for a term which shall not be less than **ten** years, which may extend to imprisonment for life, and shall also be liable to fine. The modal verbs are the law: the minimum term is mandatory ("shall not be less than"), the extension to life is discretionary ("may extend"), and the fine is a mandatory addition ("shall also be liable"). A separate sub-section lists aggravated categories - among them a police officer, a public servant, a person in a custodial or fiduciary position of trust - for which a heavier term is prescribed, reflecting the abuse of power the section singles out.

PITFALL

Citing the repealed Indian Penal Code's rape and punishment sections as the governing law for a current offence, or without first establishing when the offence was committed. The wording of the offence was carried across largely intact, which is exactly why the error is so easy: the substance feels current even though the citation is dead. A medico-legal report that names a repealed code as the live one reads as out of date and invites the court to discount the opinion. Read the governing section from the current code, and let this chapter's account of the transition settle which code applies to an older matter.

18.5 The psychiatrist and the survivor

The clinician's role is real but bounded. The psychiatrist's involvement with a survivor of a sexual offence runs along several tracks, and the examinable skill is knowing which one is in play: assessing and documenting the survivor's mental state and the psychological sequelae, as treating clinician; assessing **capacity to consent** where the section's own circumstances of unsoundness of mind, intoxication or an inability to communicate are in issue; supporting a vulnerable survivor through the process of giving evidence; and providing continuing treatment for the psychiatric consequences.

The dual role, and the line not to cross. These tracks map onto the two roles that organise all forensic work, the treating clinician who owes duties to a patient and the forensic evaluator who serves the court, and the distinction between them is developed in this chapter's account of the psychiatrist as expert witness. The critical discipline is that a psychiatrist assesses mental state and capacity but does not pronounce on the ultimate legal question of whether there was consent, which is for the court alone to decide on all the evidence. An opinion that a survivor "did not consent", or that an account is true, usurps the court's function and is worth less, not more, for its overreach. The proper contribution is narrower: whether, at the material time, this person had the capacity to understand the nature and consequences of the act, or to communicate a choice about it.

How the assessment is conducted matters as much as what it finds. A survivor examination is itself a potential source of further harm, so the assessment is trauma-informed and unhurried, with the survivor's own authorisation sought for each step and the findings recorded contemporaneously and precisely. Where the survivor is a child, the dedicated child-protection statute applies alongside the applicable general provisions, and both the substantive framework and the special procedures for a child are the province of the Child psychiatry: assessment, treatment, services and protection notes, which are named here and cross-referred, not re-taught.

IN INDIA

The sexual-offences law is one of the most heavily reformed corners of the Indian criminal code, and the psychiatrist sits inside a defined medico-legal pathway. A survivor presenting after an assault is examined under a standardised medico-legal protocol, and a psychiatric opinion on capacity to consent is sought specifically where the statute's own circumstances - unsoundness of mind, intoxication or an inability to communicate - are raised. The practical safeguard is to write every such opinion against the current code read from the primary source, and to keep the clinical capacity finding distinct from the legal conclusion the court will draw from it.

GOOD TO REMEMBER

Before you commit any opinion in a sexual-offences matter, settle two things. First, which question the court is actually asking: a clinical-capacity question about whether this person could understand or communicate, or something the law reserves to itself. Second, that your report answers the first and never trespasses on the second. State the mental state and the capacity, document how you assessed both, and stop short of the ultimate issue of consent, which is the court's to decide.

63	64	10
CURRENT PENAL-CODE SECTION THAT DEFINES RAPE	THE SECTION THAT PRESCRIBES THE PUNISHMENT	YEARS, THE MANDATORY MINIMUM RIGOROUS IMPRISONMENT

Rape is defined and punished under those two sections of the current penal code by a mandatory minimum of rigorous imprisonment extendable to life; the definition, broadened after the post-2013 reforms and carried forward unchanged, turns on the criminal-law meaning of consent in Explanation 2, an unequivocal, communicated, act-specific willingness in which non-resistance is not consent. That construct is not the clinical doctrine of informed consent. The psychiatrist assesses a survivor's mental state and capacity to consent where unsoundness of mind, intoxication or an inability to communicate is in issue, and never pronounces on the ultimate legal question of consent, which is the court's.

19 · Section 105 BSA (formerly Section 84 IPC under BNS) and updated penal code provisions

Get the citation right, or the opinion is worthless. The examinable core of this topic is small, exact and unforgiving. The insanity defence and the rule about who must prove it are two

different provisions, sitting in two different codes, and the penal and evidence codes carrying these two provisions changed on **1 July 2024**. A psychiatrist who cites the wrong section, or a repealed code, in a report to a criminal court has undermined the one thing an expert is there to supply: a precise, current and defensible statement of the law the opinion is built on. The marks here reward accuracy, not breadth, and the commonest way to lose them is to answer confidently in the language of a code that no longer governs.

The heading a candidate is most likely to meet, pairing an evidence-code section number with the old insanity section, is itself wrong, and correcting it is half the answer. This topic fixes the mapping, states what each current section actually provides, and then teaches the transition rule that decides which code governs a given case. The cognitive test that the defence turns on, and the doctrine of the burden of proof, are developed in the Mental health legislation and forensic psychiatry notes and are named here, not re-taught; the courtroom procedure for referring and assessing an accused is carried in the accompanying forensic-procedure material.

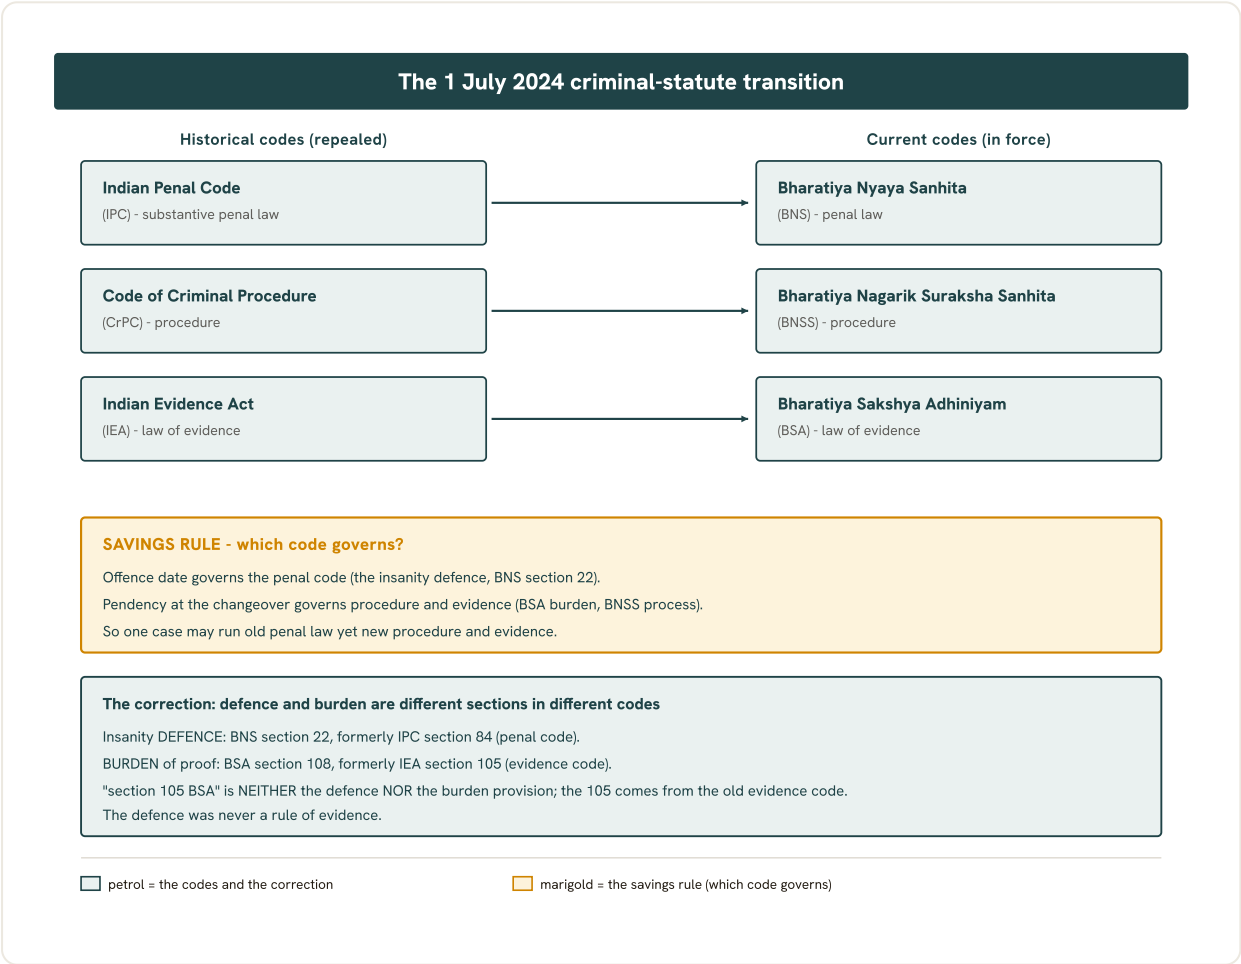

Fig 26.11. On 1 July 2024 the three colonial codes were replaced together, the Indian Penal Code by the Bharatiya Nyaya Sanhita, the Code of Criminal Procedure by the Bharatiya Nagarik Suraksha Sanhita and the Indian Evidence Act by the Bharatiya Sakshya Adhiniyam, with the offence date governing the penal code and pendency at the changeover governing procedure and evidence, so the insanity defence is BNS section 22 (formerly IPC section 84) and the burden of proof BSA section 108 (formerly IEA section 105), not section 105 BSA.

19.1 The correction: a defence and a burden, in two separate codes

Two functions, two statutes, two section numbers. The loose shorthand that files the insanity defence under an evidence-code section number collapses two entirely separate provisions into

one. The **general exceptions** to criminal liability, among them the exemption for the **act of a person of unsound mind**, live in the penal code; the rule about who must prove that an accused falls within such an exception lives in the law of evidence. These are not two names for one thing. One asks whether the act is an offence at all; the other asks who carries the risk of not proving the answer. The comparison below fixes both the function and the location.

AXIS	THE INSANITY DEFENCE	THE BURDEN OF PROVING IT
Question it answers	Given the accused's state of mind at the time, is the act an offence at all?	Once the defence is raised, who must establish that the accused was of unsound mind?
Where it lives	The penal code, among the general exceptions (the Bharatiya Nyaya Sanhita, formerly the Indian Penal Code)	The law of evidence (the Bharatiya Sakshya Adhiniyam, formerly the Indian Evidence Act)
Section, current and former	section **22**, formerly section **84**	section **108**, formerly section **105**
Nature of the rule	A general exception that exempts the act from criminal liability	A rule of evidence that places proof on the accused and directs the court to presume the exception absent

The two provisions the garbled heading conflates. Because the defence and the burden are separately located, no single section of the Bharatiya Sakshya Adhiniyam can carry the insanity defence: the popular phrasing borrows the repealed evidence-Act number and pins it to the new code, pointing at neither the defence nor its correct home.

Why the shorthand is not merely sloppy but wrong. The number in the heading was never the defence at all. In the old scheme, the exempting provision was the penal code's insanity section, and its successor is the general-exceptions insanity provision of the Bharatiya Nyaya Sanhita. The number the heading borrows belonged instead to the evidence Act's burden-of-proof provision, whose successor is the current burden section of the Bharatiya Sakshya Adhiniyam. So the correction is not a matter of updating a digit: it is recognising that the defence and the proof of it are different laws, and that the shorthand mixes an old evidence-section number with a new code's name to describe a provision that does not exist.

MNEMONIC

Defence in the Nyaya Sanhita, burden in the Sakshya Adhiniyam

The exemption for the act of a person of unsound mind sits in the penal Sanhita; the rule that the accused must prove it sits in the evidence Adhiniyam. Two functions, two codes: a single evidence-code section can never be the home of the defence, because the defence was never a rule of evidence.

RULE **The defence and the burden are different sections in different codes, and both codes changed at the transition.** The insanity exemption is a penal-code general exception (now the Bharatiya Nyaya Sanhita, formerly the Indian Penal Code); the rule that the accused must prove it is a provision of the evidence code (now the Bharatiya Sakshya Adhiniyam, formerly the Indian Evidence Act). No single provision holds both, so the popular pairing of the defence with an evidence-code number is a category error before it is a numbering error.

19.2 The insanity defence now: the penal code's act of a person of unsound mind

What the current section actually provides. The Bharatiya Nyaya Sanhita's general-exceptions insanity provision exempts from criminal liability an act done by a person who, at the time of doing it, by reason of **unsoundness of mind**, was incapable of knowing the nature of the act, or that it was wrong or contrary to law. Read the clause slowly, because each element does work: the incapacity must arise from unsoundness of mind, it must exist at the time of the act, and it is an incapacity of knowing, that is, a defect of cognition rather than of control or of motive. The exemption is framed as an absolute one, nothing done in that condition is an offence, which is why the defence, when it succeeds, negates criminal responsibility rather than merely mitigating it.

The test has a name, and it is deliberately not re-taught here. The cognitive standard the section encodes is the **M'Naghten standard**. Its limbs, the meaning of knowing the nature of the act, the distinction between legal and moral wrong, and the way the standard is applied and assessed in a real accused, are the doctrine of criminal responsibility and are developed in the Mental health legislation and forensic psychiatry notes; naming the test is the task here, unpacking it is not. One point of continuity is worth holding, however. The statutory wording of the current section is carried across word for word from the repealed penal-code provision, so the substantial body of case-law decided under the old section remains directly instructive, and nothing about the substantive test changed at the transition. What changed is the citation, not the content.

19.3 The burden of proving the defence: the evidence code's exceptions provision

The accused who raises the exception must prove it. The general rule of criminal proof, that the prosecution establishes guilt, does not extend to the general exceptions. When an accused claims to fall within an exception such as unsoundness of mind, the evidence code places the **burden of proof** on the accused: the burden of proving the existence of the circumstances that bring the case within the exception rests on the person asserting it, and the court shall presume the absence of those circumstances until they are established. The section's own first illustration is, tellingly, the insanity case itself, an accused charged with an offence who alleges that by reason of unsoundness of mind he did not know the nature of the act, on whom the burden of proof then lies. The provision does not decide guilt; it allocates who bears the risk on the question of the exception.

Where the statute stops and the doctrine begins. Note the exact structure, because candidates lose the mark by softening it. The burden is placed on the accused, and the court is directed to presume the exception absent, not merely permitted to. How heavy that burden is, and how it

interacts with the presumption of sanity and with the prosecution's own standard, is the doctrine of the burden of proof, which is developed in the Mental health legislation and forensic psychiatry notes and is named, not restated, here. What this topic owns is the location: the burden that used to sit in the repealed evidence Act now sits in the current exceptions provision of the Bharatiya Sakshya Adhiniyam, and that is the provision the garbled heading was reaching for and missing.

TRAP **Naming the evidence code's burden section as the home of the insanity defence.** The number in the garbled heading is borrowed from the repealed evidence Act's burden-of-proof provision, not from the penal code at all, and the defence never lived in the law of evidence. Candidates conflate the two because the exempting section and its burden are examined together, but the provision that exempts the act and the provision that allocates its proof are separate laws in separate codes, and an answer that fuses them has misunderstood the topic, not merely mistyped a digit.

19.4 The transition and the savings rule

The date is not a light switch. On the transition the three colonial-era codes were repealed and replaced together: the penal code, the evidence Act and the code of criminal procedure gave way to the Bharatiya Nyaya Sanhita, the Bharatiya Sakshya Adhiniyam and the **Bharatiya Nagarik Suraksha Sanhita**. Each replacing Act carries its own **repeal and savings** clause, and those clauses are the reason a clinician cannot simply assume that the newest code is the one in force for the matter in front of them. Repeal removes a statute going forward; the savings clause decides what happens to everything already under way.

The penal code follows the date of the offence. The savings clause of the penal Sanhita repeals the Indian Penal Code but preserves its previous operation for what has already happened under it. In particular it keeps the old code alive for offences committed before the change, so that the substantive law, including the insanity defence, is judged by the penal code in force on the **offence date**. Concretely, the savings clause preserves:

- the previous operation of the repealed code, and anything duly done under it;
- any right, obligation or liability already acquired, accrued or incurred;
- any penalty or punishment incurred for an offence already committed against the repealed code;
- any investigation, proceeding or remedy in respect of such a matter, which may be instituted, continued or enforced as if the code had not been repealed.

Procedure and evidence follow pendency, not the offence date. The savings rule for the other two codes turns on a different pivot. Where a trial, inquiry, application, appeal or investigation was already **pendency** pending immediately before the transition, that matter is dealt with under the old evidence Act and the old procedure code, as in force before the change, as if the new codes had not come into force. So the currency of procedure and evidence follows whether the proceeding was pending at the transition, while the currency of the penal code follows when the offence was committed. This asymmetry is the examinable subtlety: a single case can be governed

by the old penal code for its offence and defence, yet by the new procedure and evidence codes for its trial, if the offence predated the change but proceedings began after it.

19.5 Which code governs the matter in front of you

The first question in any criminal referral. The practical payoff of the savings rule is a discipline that must run before any opinion on criminal responsibility is committed to paper. The psychiatrist is not the arbiter of which code applies, that is for the court, but the report must be framed in the law that actually governs, and getting it wrong signals to the court that the expert is working from stale knowledge. Two questions settle the framing:

- When was the offence committed? That fixes the penal code, and therefore the section under which the insanity defence is judged.
- Was the proceeding pending at the transition? That fixes the procedure and evidence law, and therefore the provision under which the burden of proof is allocated.

Name the current provision by its current name. Once the two questions are answered, the report should cite the governing code and section correctly and consistently, and should not drift between old and new names within the same document. Where the current codes govern, the defence is the general-exceptions insanity provision of the Bharatiya Nyaya Sanhita and the burden rule is the exceptions provision of the Bharatiya Sakshya Adhiniyam. Where the savings rule keeps an older matter alive, the report should say so explicitly, rather than silently using whichever names the clinician happens to remember.

IN INDIA

For years to come, Indian forensic practice will run old-code and new-code cases side by side, because the offence date and pendency, not the calendar, decide which law applies. A psychiatrist writing reports today will still meet matters governed by the repealed penal, evidence and procedure codes, alongside matters under the new Sanhita, Adhiniyam and the successor procedure code, sometimes within a single case. The safe habit is to read the governing provision from the primary code rather than from memory or an old handout, and to state, in the report, the code and section the opinion is written against.

GOOD TO REMEMBER

Before you frame any opinion touching criminal responsibility, establish two facts and record them at the top of the report: the date the alleged offence was committed, and whether proceedings were already pending at the transition. Those two facts, not the current year, tell you which penal code carries the defence and which evidence and procedure code carries the burden and the process. Everything else in the medico-legal opinion is built on that footing.

PITFALL

Citing the Indian Penal Code, the Indian Evidence Act or the Code of Criminal Procedure as the current law in a report written after the transition. It is an easy error, because the wording of the insanity defence did not change and the old citations are deeply familiar, but a report that names a repealed code as the governing law reads as out of date and invites the court to discount the opinion. The wording continuing unchanged is exactly why the citation, not the content, is where the mistake hides.

22	84	108	105
BHARATIYA NYAYA SANHITA SECTION CARRYING THE INSANITY DEFENCE	THE REPEALED INDIAN PENAL CODE SECTION IT REPLACED	BHARATIYA SAKSHYA ADHINIYAM SECTION PLACING THE BURDEN ON THE ACCUSED	THE REPEALED INDIAN EVIDENCE ACT SECTION IT REPLACED

The insanity defence is the penal code's general exception for the act of a person of unsound mind (the Bharatiya Nyaya Sanhita, formerly the Indian Penal Code); the burden of proving it rests on the accused under the evidence code, which also directs the court to presume the exception absent (the Bharatiya Sakshya Adhiniyam, formerly the Indian Evidence Act). They are separate sections in separate codes, so an evidence-code number can never be the insanity defence. The penal code follows the date of the offence; procedure and evidence follow whether the matter was pending at the transition.

20 · Procedure for psychiatric assessment of an accused (Sections under CrPC/BNSS, court referral)

A criminal court cannot try a defendant it cannot reach. When an accused's mental state puts their ability to follow and answer the case in doubt, the criminal procedure code does not leave the matter to the clinician's goodwill: it lays down a defined pathway by which the court itself obtains, records and acts on a psychiatric assessment of an accused. This topic is procedure, not doctrine. It governs three linked steps - how the court refers, how the person is examined, and what the court does with the report - and the disposal that follows once a finding of incapacity is recorded. The marks reward the sequence and the exact duties, not the headline that an unfit accused is referred for assessment.

Two features frame everything below. First, the question can surface at two different points in a prosecution, and each has its own section: while a Magistrate is holding an **inquiry** before trial, and once the **trial** itself is under way. Second, the assessment is anchored to a present-tense question - whether the person is **incapable of making his defence** - which is the construct of fitness to stand trial. The criteria that decide fitness are developed in the Mental health legislation and forensic psychiatry notes and are named here, not restated; likewise the separation of the treating from the forensic role belongs to the accompanying material on the psychiatrist as expert witness, and the rules that govern how the resulting opinion is received in court belong to the accompanying material on court structure and the rules of evidence. What this topic owns is the procedural spine that connects them.

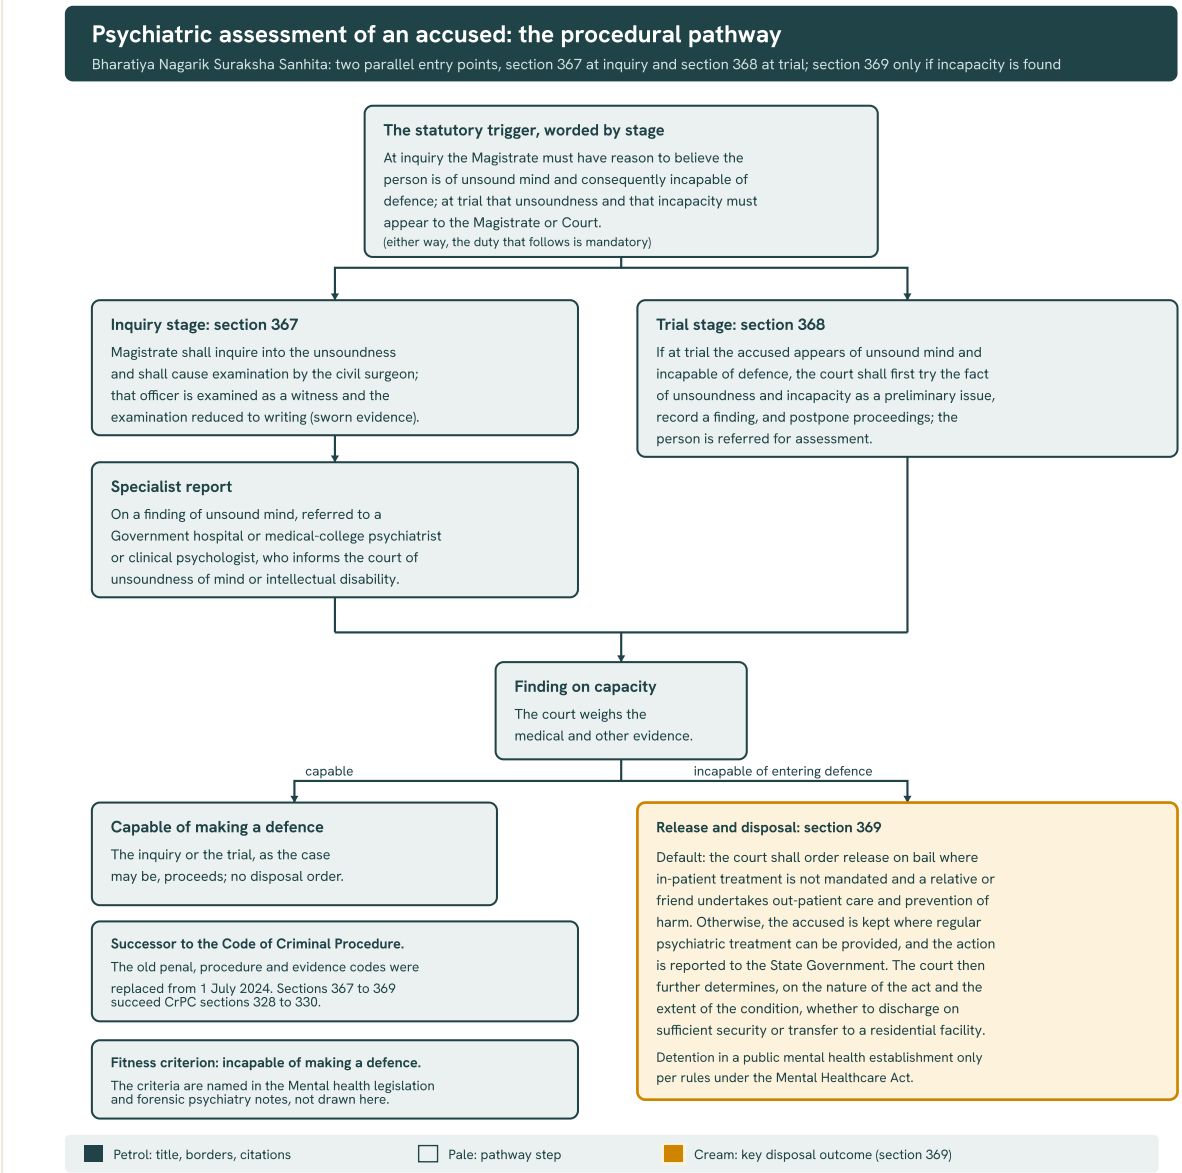

Fig 26.12. The psychiatric assessment of an accused under the Bharatiya Nagarik Suraksha Sanhita has two parallel entry points, worded differently. Under section 367, where a Magistrate holding an inquiry has reason to believe the person is of unsound mind and consequently incapable of defence, the Magistrate shall inquire into that unsoundness and shall cause the prescribed medical examination. Under section 368, where unsoundness and incapacity appear to the Magistrate or Court at trial, the court shall first try the fact of unsoundness and incapacity. A finding of capacity lets the inquiry or the trial proceed; a finding that the accused cannot enter a defence leads to disposal under section 369: release on bail where in-patient treatment is not mandated and an undertaking is given, otherwise safe custody with regular psychiatric treatment reported to the State Government, and a further determination whether to discharge on sufficient security or transfer to a residential facility. These provisions succeed Code of Criminal Procedure sections 328 to 330.

20.1 The pathway and the code it lives in

One question, two entry points, three provisions. The current procedure code is the Bharatiya Nagarik Suraksha Sanhita, the successor to the Code of Criminal Procedure. It carries the unsound-mind machinery in three consecutive sections that read as a single scheme: a referral-and-report provision for the inquiry stage, a parallel provision for the trial stage, and a disposal provision for a person found under either to be unable to enter a defence. The reason the law splits the referral across two sections is that the disability can become apparent before the case is

fully framed or only after evidence has begun, and the safeguard that no one is tried while unable to participate must be available at both moments. The disposal provision sits downstream of both, because a finding of incapacity raises the same practical question however it is reached.

The trigger is worth stating precisely, because it is where the court's duty attaches, and the two entry points word it differently. It is not enough that the accused is unwell or behaving oddly. At the inquiry stage the provision bites when the Magistrate has reason to believe the person is of **unsoundness of mind** and consequently incapable of making a defence; at the trial stage it bites when that unsoundness and that incapacity appear to the Magistrate or Court. The wording differs, the conjunction does not: a mental state together with its consequence for participation opens the pathway, and neither alone will do.

RULE **Once the Magistrate holding an inquiry has reason to believe the accused is of unsound mind and consequently incapable of making a defence, the duty to inquire and to obtain a medical examination is mandatory, not discretionary.** The statute says the Magistrate shall inquire into the fact of unsoundness and shall cause the person to be examined; it is not a power the court may exercise if it chooses. A candidate who writes "the court may refer" has changed the law, because a discretionary power and a mandatory duty are different provisions.

20.2 Referral, examination and report at the inquiry stage

The core provision, step by step. The referral-and-report section of the current code is the one to know in full, because the trial-stage provision and the disposal provision both take their shape from it. When a Magistrate holding an inquiry has reason to believe the person is of unsound mind and consequently incapable of making a defence, four mandatory steps follow in order:

1. inquire into the fact of the unsoundness of mind;
2. cause the person to be examined by the **civil surgeon** of the district, or such other medical officer as the State Government directs;
3. examine that surgeon or officer as a witness; and
4. reduce that examination to writing.

Each step is deliberate: the examination is sworn evidence taken on the record, so the court's later finding rests on testimony that can be tested, not on an informal impression.

From the first-line examiner to the specialist. The section then builds in an escalation. If the civil surgeon finds the accused to be of unsound mind, the surgeon shall refer the person to a psychiatrist or **clinical psychologist** of a Government hospital or Government medical college for **care, treatment and prognosis** of the condition. The specialist, in turn, shall inform the Magistrate whether the accused is suffering from unsoundness of mind or from **intellectual disability**. Two points repay attention. The specialist referral is triggered by the first examiner's finding, so the civil surgeon is the gatekeeper of the pathway rather than its endpoint; and the specialist's report is framed as the binary the court needs, unsoundness of mind or intellectual disability, because the two carry different implications for whether the person can be tried and

treated. An appeal against the specialist's opinion lies to a Medical Board, whose exact composition is recorded in this topic's gaps rather than asserted from memory.

MNEMONIC

Believe, Inquire, Examine, Report, Dispose

The five beats of the pathway in order: the court must have reason to **believe** the accused is of unsound mind and unable to defend; it must **inquire** into the fact; it must have the person **examine**d, first by the civil surgeon and then, on a finding, by a Government-facility specialist; the specialist must **report** unsoundness of mind or intellectual disability; and the court must then **dispose** of the person under the release provision.

20.3 The parallel provision at the trial stage

The same safeguard, one step later in the process. The trial-stage section is the mirror of the inquiry-stage provision for the point at which the case has reached trial. If, at the trial of a person before a Magistrate or a Court of Session, it appears to the court that the person is of unsound mind and consequently incapable of making a defence, the court shall, in the first instance, try the fact of that unsoundness and incapacity. It is a preliminary issue that must be resolved before the substantive trial can go further: the court considers such medical and other evidence as is produced, and if it is satisfied of the fact, it shall record a finding to that effect and shall postpone further proceedings in the case. The structure matters: the court does not simply accept the medical report but tries the fact on evidence, which is why the psychiatric assessment enters as evidence to be weighed rather than as a verdict to be rubber-stamped.

Fitness is the criterion, and it is not decided here. Both this provision and the inquiry-stage one turn on whether the accused is capable of entering a defence, which is the fitness-to-stand-trial question. What that capacity consists of - what the person must be able to understand and do to be tried fairly - is the fitness construct owned by the Mental health legislation and forensic psychiatry notes, and it is named here and cross-referred, not enumerated. This topic owns the machinery that surrounds the criterion: who refers, on what trigger, with what evidence, to what recorded finding. Keeping the fitness question apart from the responsibility question is the discipline the exam is testing.

TRAP **Reading this assessment as an opinion on the insanity defence.** The question this pathway asks is present-tense: can the accused understand and participate in the proceedings now. That is fitness to stand trial, decided by the court after medical evidence. It is a different question from criminal responsibility, which asks about the accused's mind at the time of the offence and is governed by the insanity defence and its burden - the criminal-responsibility doctrine developed in the Mental health legislation and forensic psychiatry notes. A report that answers the responsibility question when the court asked the fitness question has answered the wrong provision, and candidates lose the mark by fusing the two.

20.4 Release and disposal after a finding of incapacity

What happens to the person while the case stands still. The final section of the scheme governs the disposal of a person found, under either of the two referral provisions, to be

incapable of entering a defence by reason of unsoundness of mind or intellectual disability. Its default is liberty with treatment, and the modal force matters: whether or not the case is one in which bail may ordinarily be taken, the court shall order **release on bail** where the person's condition does not mandate in-patient treatment and a relative or friend gives an undertaking that the person will receive out-patient psychiatric treatment and be prevented from harm. Only where, in the court's opinion, bail cannot be granted, or where no appropriate undertaking is given, does the fallback apply: the court shall then order the accused to be kept in a place where **regular psychiatric treatment** can be provided, and shall report the action taken to the State Government. Drop the conditions and the answer is wrong: safe custody is not the norm but what remains when supervised community release is unavailable. The section does not stop there: keeping in view the nature of the act committed and the extent of the unsoundness of mind or intellectual disability, the court further determines whether release can be ordered, and may either discharge the accused on sufficient security or, where discharge cannot be ordered, transfer the accused to a residential facility for persons with unsoundness of mind or intellectual disability.

The one hard limit on where the person may be held. The section closes with a proviso that a candidate should be able to reproduce in substance: no order for the detention of the accused in a public mental health establishment shall be made otherwise than in accordance with the rules made by the State Government under the Mental Healthcare Act, **2017**. This is the seam where criminal procedure hands off to mental health law. The procedure code decides that the person is to be kept and treated; it does not itself authorise admission to a mental health establishment. The definitions, the admission machinery and the review boards under that Act belong to the Mental health legislation and forensic psychiatry notes and are named here, not taught.

GOOD TO REMEMBER

Write the report to the question the court actually asked. The referring provision wants to know two things: whether the person is of unsound mind or has an intellectual disability, and whether that condition makes them unable to follow and answer the case. Address prognosis and treatability, because the disposal provision turns on them, and say plainly whether supervised out-patient care under a relative's undertaking is feasible, the court's preferred route before custody for treatment. An opinion pitched at the wrong question, however clinically sound, does not help the court apply the section.

20.5 The psychiatrist's place in the pathway, and getting the code right

The expert serves the court, not the accused. Within this procedure the psychiatrist or clinical psychologist enters as an examiner and reporter to the court, a role distinct from that of a treating clinician who owes duties to a patient. Where the person is not already under one's care, the assessment is a forensic evaluation whose client is effectively the court, and the report must be framed accordingly: neutral, addressed to the statutory question, and defensible on cross-examination. The full separation of the treating role from the expert role, and the way opinion evidence is distinguished from fact evidence and received by the court, are developed in the

accompanying material on the psychiatrist as expert witness and the accompanying material on court structure and the rules of evidence.

Which code governs the case in front of you. Because the procedure code changed at the recent transition, the psychiatrist must be careful to frame the report in the law that actually governs. For matters already under way before the change, the corresponding provisions of the repealed Code of Criminal Procedure may still govern the proceeding, while current matters run under the successor sections described above. The savings rule that decides which code applies to a given case, and the wider transition from the old penal, procedure and evidence codes, is owned by the accompanying material on the current penal-code framework and the transition. What this topic asks of the clinician: read the governing section from the primary code, cite it correctly, and do not drift between the old and new names within a single report.

IN INDIA

The pathway is built around the public system. The first examiner is the district civil surgeon or a medical officer the State Government directs, and the specialist referral runs specifically to a psychiatrist or clinical psychologist of a Government hospital or Government medical college, not to any qualified practitioner the accused might prefer. Detention for treatment, when it comes to that, is permitted only in a place where regular psychiatric treatment can be provided, and admission to a public mental health establishment is tied to the rules made under the Mental Healthcare Act. In practice this concentrates forensic assessment in a small number of Government facilities, which is where delay and waiting-list pressure tend to accumulate.

AXIS	AT THE INQUIRY STAGE	AT THE TRIAL STAGE	ON A FINDING OF INCAPACITY
Governing section (current code)	section **367**	section **368**	section **369**
When it operates	During a Magistrate's inquiry, before trial	During trial before a Magistrate or Court of Session	After a finding under either provision that the person cannot enter a defence
What the court shall do	Inquire into the unsoundness and cause the person to be examined	Try the fact of unsoundness and incapacity as a preliminary issue	Order release on bail with an undertaking, or safe custody with treatment
Who examines or treats	Civil surgeon or directed medical officer, then a Government-facility psychiatrist or clinical psychologist	Court weighs medical and other evidence; specialist assessment on reference	A place where regular psychiatric treatment can be provided
The recorded output	Examination taken as sworn evidence and reduced to writing; report of unsoundness or intellectual disability	A recorded finding of unsoundness and incapacity; proceedings postponed	Action taken reported to the State Government

The three-provision scheme read across its two entry points and its single disposal route. The inquiry-stage and trial-stage provisions are parallel referral routes to the same fitness question; the disposal provision sits downstream of both.

PITFALL

Citing the Code of Criminal Procedure sections as the current law in a report or answer written after the transition. The old numbers are deeply familiar and the scheme has carried across largely intact, which is exactly why the error hides in the citation rather than the content. A report that names a repealed procedure code as the governing law reads as out of date, and a candidate who cannot say whether the old or the new code applies to a given matter has missed the savings rule that decides it.

328	329	330
THE REPEALED PROCEDURE-CODE SECTION FOR THE INQUIRY-STAGE REFERRAL AND REPORT	THE REPEALED TRIAL-STAGE PROVISION IT REPLACED	THE REPEALED DISPOSAL AND REPORTING PROVISION IT REPLACED

The psychiatric assessment of an accused runs on a three-section scheme in the current procedure code: a referral, examination and report at the inquiry stage; a parallel provision at the trial stage where the court shall first try the fact of unsoundness and incapacity; and a disposal provision under which the court shall order release on bail where in-patient treatment is not mandated and an undertaking is given, or safe custody with regular psychiatric treatment reported to the State Government, and shall further determine whether to discharge the accused on sufficient security or transfer them to a residential facility. The trigger is unsound mind that makes the accused incapable of defence, the duty to refer is mandatory, and the criterion is fitness to stand trial, which is named here and taught in the Mental health legislation and forensic psychiatry notes.

21 · Dying declaration and psychiatric assessment of competence

Why this earns marks. The **dying declaration** is one of the few rules of evidence in which the psychiatrist is not a bystander but a participant. The treating team is often the only body present when a fatally injured person names how the injury came about, and a court will later ask whether that person was in a fit enough mental state for the statement to be believed. Two competencies are being tested at once: a point of substantive evidence law, and a bedside psychiatric judgement about capacity. Candidates who can hold the two apart, and then join them, score cleanly. The evidence rule tells you what such a statement is worth in principle; the psychiatric assessment tells you what this particular statement, from this particular declarant, is worth in fact.

The provision must be read from the current code. The substantive criminal law of India was recently recast, and the older evidence statute is now historical; the transitional savings rule that decides which code governs a case already pending at the changeover is set out where this chapter treats the penal-code framework, and is not re-derived here.

21.1 The provision: what the statute makes relevant

The dying declaration is governed by section **26(a)** of the Bharatiya Sakshya Adhiniyam, the successor to what was section **32(1)** of the Indian Evidence Act. Ordinarily a statement made out of court by a person who is not before the court to be cross-examined is hearsay and cannot be received. The dying declaration is a recognised exception: a statement by a person as to the cause of his death, or as to any of the circumstances of the transaction that resulted in his death, is a relevant fact whenever the cause of that person's death comes into question. The rationale traditionally offered is twofold - necessity, because the best witness to the killing is now dead and cannot be produced, and a presumption of trustworthiness, the old intuition that a person who feels death approaching is unlikely to leave the world with a lie on the lips. The second limb of that rationale is exactly where Indian law then parts company with the tradition that produced it.

21.2 The Indian departure: no expectation of death, and any proceeding

This is the discrimination examiners most want to see. In the English common-law tradition the exception is narrow: the maker must have been under a settled, hopeless **expectation of death** at the moment of speaking, and the statement is admissible essentially only on a charge concerning the declarant's own homicide. The Indian statute is deliberately wider. The statement is relevant whether or not the maker was, at the time it was made, under any expectation of death, and whatever the nature of the proceeding in which the cause of death comes into question. A declarant who fully expected to recover, and who only later died, may still have made a relevant dying declaration; and the statement may be used in a civil suit as much as in a criminal trial. The maker's belief about survival has not been abolished from the analysis - it survives as a factor going to how much the statement is trusted - but it has been removed as a precondition of receiving it at all.

RULE **Under Indian law the maker need not have expected to die, and the statement is not confined to a homicide trial.** The statute makes the statement a relevant fact whenever the cause of death is in question, whatever the proceeding; the settled, hopeless expectation of death is the English precondition, not ours. The declarant's belief about survival goes to weight, never to admissibility.

Not required
EXPECTATION OF DEATH

Any proceeding
WHERE CAUSE OF DEATH IS IN ISSUE

Fit mind
WHAT THE STATEMENT'S WEIGHT TURNS ON

AXIS OF COMPARISON	ENGLISH COMMON-LAW TRADITION	INDIAN STATUTORY POSITION
Expectation of death	Required: a settled, hopeless expectation when speaking	Not required; relevant to weight only
Proceedings covered	Essentially the declarant's own homicide	Any proceeding where the cause of death is in question
Use in a civil dispute	Not available	Available
Effect if the maker expected to live	Statement excluded	Statement still relevant

TRAP **Importing the English precondition into Indian law.** Candidates who learned the topic from older or foreign texts write that the declarant must have abandoned all hope of life. In India that is wrong: the expectation of death was deliberately dropped from the statutory test, and stating it as a condition of admissibility loses the mark even when the rest of the answer is sound.

21.3 Admissibility is not reliability: the requirement of a fit mind

Where the psychiatrist enters. That the statement is a relevant fact settles only that the court may receive it. What the court then does with it - how far it relies on it, whether it convicts on it alone - is a separate question of weight, and here the declarant's mental state becomes decisive. A dying declaration carries no oath and cannot be tested by cross-examination, the two ordinary safeguards of testimony, so the court leans heavily on being satisfied that the maker was **compos mentis**. Fitness in this sense has two layers, and it helps to name them separately:

- A **physical capacity to communicate** - the declarant can produce a statement at all, by speech, gesture or sign.
- A **mental capacity** to understand what is asked and to give a rational, self-consistent account of it.

It is the second that is the psychiatric question. Note precisely what it is not: it is not whether the declarant told the truth, which is for the court to decide, but whether the declarant had the **capacity** to give a reliable statement in the first place. The psychiatrist assesses the instrument, not the tune played on it.

IN INDIA

A dying declaration is most safely recorded by a judicial magistrate, but the fatally injured are usually in casualty, and in practice the recording frequently falls to the attending medical officer or the investigating police. The settled expectation is that the treating doctor certifies, ideally both before and after the statement is taken, that the patient was conscious and in a fit state of mind to make it. Where a psychiatrist is available, that certification of mental fitness is exactly the contribution asked of them. The certificate should record the examination actually done, not merely assert a conclusion, because a bare line that the patient "was conscious" is worth little when it is later challenged.

21.4 The competence assessment at the bedside

The assessment is a focused mental-state examination directed at a single question: could this person, at this moment, take in a question, understand it, retrieve the relevant memory, and express a rational answer? The domains to examine are the familiar ones, sharpened to that purpose:

- **Consciousness and the sensorium** - alert, drowsy, fluctuating or obtunded; a clouded sensorium is a leading reason a declaration's weight is later doubted.
- **Attention and comprehension** - can the patient hold attention long enough to follow a question to its end and grasp what is being asked.

- **Coherence and memory** - a connected, internally consistent narrative of the event, drawn from recall rather than confabulated across a gap.
- **Freedom from tutoring** - whether the account was prompted, led or coached by relatives or police crowding the bedside. This goes to the reliability of the recording rather than to the declarant's mental capacity, so the clinician documents what was observed at the bedside and leaves the effect of any tutoring for the court to weigh.

MNEMONIC

Is the mind CLEAR?

Consciousness unclouded; **L**evel of attention sustained; **E**xpression coherent and comprehension intact; **A**nswers rational and internally consistent; **R**ecall of the event in the patient's own words. CLEAR is a bedside prompt, not a formula: fitness remains a case-specific conclusion supported by the recorded examination.

GOOD TO REMEMBER

Document the examination contemporaneously and in the patient's own words: the exact questions put, the exact answers given, the time, and the state of the sensorium at that time. A record showing the questions posed and the rational replies received is far stronger in court than a later assertion that the patient was "conscious and oriented". If the sensorium is fluctuating, assess and certify fitness immediately before the statement is taken, because capacity present an hour earlier does not establish capacity at the moment of the declaration.

21.5 Conditions that cloud the declarant's mind

Where competence actually fails. Almost every dying declaration is taken from a patient who is, by definition, gravely injured or ill, and the same processes that threaten life threaten the sensorium. The psychiatrist should look actively for the states below rather than presume fitness from the fact that the patient is talking; fluent speech and a clear mind are not the same thing. **Delirium** in particular can coexist with apparently purposeful conversation.

THREAT TO COMPETENCE	MECHANISM	WHAT THE ASSESSMENT FOCUSES ON
Extensive burns	Shock, toxaemia and hypoxia cloud the sensorium; pain and dehydration compound it	Alertness and coherence now, not the proportion of surface burnt, which does not by itself decide fitness
Head injury	Raised intracranial pressure, contusion and post-traumatic amnesia	Consciousness, orientation, and whether the event itself can be recalled
Haemorrhage and hypoxia	Cerebral hypoperfusion and hypoxaemia impair attention and thought	Sustained attention and fluctuation over minutes
Acute intoxication	Alcohol or other substances disinhibit and disorganise; withdrawal may bring delirium	Slurring, disinhibition, and the ability to give a consistent account
Sedation and analgesia	Opioids and sedatives blunt the sensorium precisely as pain relief is given	Timing relative to the last dose and the depth of sedation
Delirium	Fluctuating attention, disorganised thinking and altered awareness	Attention, fluctuation, disorganisation and perceptual disturbance
Psychotic or demented state	Delusional content or established cognitive impairment may distort the account	Whether the narrative is reality-based and internally consistent

A recurring bedside error concerns burns. The extent of a burn is frequently taken as a proxy for mental fitness, so that a very large burn is assumed to render the patient incompetent and a smaller one is assumed to leave competence intact. Neither inference is safe. The burnt surface tells you about prognosis and physiology, not directly about the sensorium, and a coherent contemporaneous assessment of mental state is what the question actually requires.

PITFALL

Do not anchor a report or certificate to the repealed evidence statute. The dying-declaration provision now sits in the Bharatiya Sakshya Adhiniyam; the corresponding section of the Indian Evidence Act is historical and reaches a case only through the transitional savings rule. A certificate that cites the old provision as the live law reads as out of date and quietly undermines the very reliability the psychiatrist is there to support.

21.6 Weight, corroboration and the limits of the opinion

Because it is untested by cross-examination, a dying declaration is scrutinised closely for reliability before a court acts on it, and a mentally fit declarant is central to that scrutiny; the general rules of evidence, and how a court treats and corroborates such a statement, are set out where this chapter treats the psychiatrist in court and the rules of evidence. The psychiatrist's contribution stays within its lane. We opine on capacity - whether the declarant was able to perceive, remember and communicate - and not on veracity, which is the court's exclusive

province. The separation of the treating clinician's role from that of the forensic evaluator, and of opinion evidence from fact evidence, is discussed where this chapter treats the psychiatrist as expert witness; the same discipline applies here, because the doctor who both resuscitates the patient and certifies fitness is wearing two hats at once and should say clearly which one each part of the record belongs to.

> A dying declaration is relevant under the Bharatiya Sakshya Adhiniyam whether or not the maker expected to die and in any proceeding where the cause of death is in issue; its weight, however, turns on the declarant having been of fit mind, and that fitness is the psychiatric question.

22 · Court structure, the psychiatrist in court and rules of evidence

Why the marks are here. A psychiatric opinion is only as good as the forum that receives it and the rule that lets it in. A report may be clinically impeccable, but if the psychiatrist does not know which court has summoned them, or cites the provision that admits their opinion in the language of a repealed code, the credibility of the whole exercise is undercut before a word of the clinical reasoning is read. Examiners test this because it is where a well-trained clinician is most easily caught out: the medicine is sound, the legal frame is out of date. Two things must be exact - the structure of the courts a psychiatrist may testify before, and the evidentiary rule under which their opinion is admitted.

This section teaches the statutory hierarchy of the criminal courts and the **rules of evidence** that govern how an expert opinion is received, both read from the current codes. The separation of the treating role from the expert role, and the advisory weight an opinion carries once admitted, are set out elsewhere in this chapter and are named here only; the substantive test of criminal responsibility, and the burden of proving it, belong to the Mental health legislation and forensic psychiatry notes and are not re-taught here.

22.1 The statutory ladder of the criminal courts

The current code of criminal procedure sets out, at section **6**, the classes of criminal court that exist in every State, and it is before these classes that a psychiatrist may be called to testify; the powers to summon a witness or to order a psychiatric assessment come from other provisions, not from this section. The provision is framed as a mandatory one: besides the High Courts and any courts constituted under other laws, every State shall have the classes of criminal court it enumerates. The enumerated classes are the **Courts of Session**; the **Judicial Magistrates of the first class**; the Judicial Magistrates of the second class; and the **Executive Magistrates** - the first three exercising judicial trial power in descending order, while the Executive Magistrate exercises executive and public-order functions rather than the trial of offences. The word "besides" does real work: it places the High Courts outside and above this list of State classes. The Supreme Court of India, higher still, is the constitutional apex, but its position is established by the Constitution and not by this section, which does not mention it.

The distinction the section draws between the two kinds of magistrate is the one most often missed. The Judicial Magistrate exercises judicial functions - trying offences, taking evidence, convicting and sentencing within the limits of the class - and it is before a Judicial Magistrate or a Court of Session that a psychiatrist's evidence on a contested criminal question is usually led. The Executive Magistrate performs executive and public-order functions rather than the trial of offences, and a psychiatrist encounters this office in the machinery that surrounds custody and order rather than in the trial.

COURT	PLACE IN THE LADDER	WHERE THE PSYCHIATRIST MEETS IT
Supreme Court of India	Constitutional apex, above the High Courts	Rarely in person; its judgments set the law the report must follow
High Court	Sits besides and above the State classes	Appeals and references turning on a psychiatric question
Court of Session	Highest of the State trial classes	Trial of the graver offences where responsibility is in issue
Judicial Magistrate (first and second class)	The magistracy exercising judicial trial functions	Trial of lesser offences; taking of evidence and committal
Executive Magistrate	Executive and public-order functions, not trial	Order-maintenance and custodial machinery, not the trial itself

The statutory classes under the current procedure code, with the High Courts and the Supreme Court above the State list. The section fixes the classes; which class hears a given matter turns on the offence and the stage of proceedings.

MNEMONIC

Sessions sit highest, Judicial magistrates try, Executive magistrates keep order

Read the State ladder top to bottom: Court of Session, then Judicial Magistrate of the first and then second class, then the Executive Magistrate. The first three are judicial and try offences; the last is executive and keeps public order. The High Courts sit besides and above the whole list, and the Supreme Court above them.

22.2 Why the forum matters to the report

The court decides the shape of the answer. Knowing the ladder is not academic. The court issuing the summons frames the question being asked and identifies the person to whom the duty of the evidence is owed, which is the court and not the party who arranged the attendance; the standard of proof, by contrast, is fixed by the nature of the proceeding and the law that governs it, not by the court that issues the summons. The scope of the opinion is set by the question the court has framed and not by the rank of the court that framed it: a magistrate's inquiry may call for a comprehensive assessment while a Court of Session may want one narrow issue answered, and accuracy, transparency and defensibility are owed in equal measure to every court. A psychiatrist who does not register what was actually asked either over-answers a small question or under-serves a large one. The pathway by which an accused is referred for assessment is a

separate topic set out elsewhere in this chapter; what matters here is that it ordinarily proceeds before one of the courts named above, subject to any special court constituted under another law.

GOOD TO REMEMBER

Before writing a line, establish which court has called you and in what capacity. Match the report to the forum: state the court, the question as the court framed it, and the material examined. Because a treating psychiatrist's own records can be summoned as evidence of fact in any of these courts, contemporaneous and legible documentation is a medico-legal protection long before a summons ever arrives.

22.3 The rule that admits an expert opinion

The ordinary rule of evidence is that a witness may speak only to facts they personally perceived, because drawing inferences from facts is the court's own work. The expert is the deliberate exception, and the current evidence code fixes that exception at section **39**, the successor to the corresponding provision of the repealed Indian Evidence Act. The rule is precise about when it operates: it is only when the court has to form an opinion upon a point of science, art, foreign law, any other field, or the identity of handwriting or finger impressions that the opinions of persons specially skilled in that field are, in the language of the code, **relevant facts**, and the persons who give them are called **experts**. The trigger is the court's own need for specialised knowledge it does not itself possess; where no such need arises, the exception does not open and an opinion is not received.

Two features of the current section repay attention:

- its illustrations expressly include the psychiatric question, one being precisely whether a person was, by reason of unsoundness of mind, in a particular mental state, the evidentiary hook on which psychiatric testimony hangs;
- it has been modernised for the digital age, a sub-section making the **Examiner of Electronic Evidence** an expert so that opinions on electronic records are admitted on the same footing.

For the psychiatrist the first of these is load-bearing: the code does not merely tolerate psychiatric opinion, it names unsoundness of mind as a paradigm of the specialised question an expert exists to address.

RULE **Expert opinion is admitted only where the court needs specialised knowledge to form its own opinion.** When the court has to form an opinion on a point of science, art, foreign law, any other field, or the identity of handwriting or finger impressions, the opinions of persons specially skilled in that field are relevant facts, and those persons are experts. The psychiatric question of unsoundness of mind falls squarely within the field the section describes.

22.4 A relevant fact, not a verdict

Calling the opinion a relevant fact is exact, and it marks the boundary of what the evidence rule delivers. Admissibility is one question and weight is another. The expert-opinion section makes the opinion admissible, that is, something the court is entitled to consider; it does not make it binding, and it does not transfer the decision to the expert. The distinction between fact evidence

and opinion evidence, and the advisory character an admitted opinion carries, is the treating-versus-expert material developed elsewhere in this chapter and is only named here. What the evidence rule itself contributes is narrower: it opens the door through which a specialised opinion may pass, on a defined class of question, given by a person specially skilled. What the court then does with the opinion is a matter of weight, not of the rule that let it in.

TRAP **Citing the repealed evidence and procedure codes as current.** Candidates and clinicians reach for the section numbers of the old Indian Evidence Act and the old Code of Criminal Procedure, the codes they trained on, when stating the rule that admits their opinion or the court that will hear it. Those codes are historical; the expert-opinion rule and the classes of criminal court are now provisions of the current evidence code and the current procedure code. An opinion built on a repealed citation is easy to discredit, however sound the psychiatry beneath it.

22.5 The psychiatric question inside the rules of evidence

Several distinct evidentiary questions bring the psychiatrist into this framework, and it is worth separating them so that each is answered under the right rule and the right owner. They are:

- the admissibility of psychiatric opinion itself, which is the expert-opinion rule owned here, with unsoundness of mind named in the section's own illustration;
- the substantive test of criminal responsibility and the burden of proving it, which the illustration points toward but does not decide, and which belong to the Mental health legislation and forensic psychiatry notes;
- the assessment of a declarant's competence when a dying declaration is offered in evidence, a distinct evidence rule set out elsewhere in this chapter;
- the procedure for referring and assessing an accused, whose pathway is likewise carried elsewhere in this chapter.

Keeping these apart is the discipline the topic rewards. The evidence rule tells you that a psychiatric opinion on unsoundness of mind is receivable; it does not tell you what the test of unsoundness is, nor who must prove it, nor how heavy that burden sits. Those belong to the doctrine of criminal responsibility, and answering them here would blur the very line the evidence rule draws. The section admits the opinion; the doctrine, taught in the Mental health legislation and forensic psychiatry notes, decides what the opinion must establish.

IN INDIA

Both provisions a psychiatrist relies on in a criminal court are now Indian statutes of recent vintage: the classes of criminal court are fixed by the current procedure code, which replaced a post-independence Code of Criminal Procedure, and the admissibility of expert opinion by the current evidence code, which replaced the colonial-era Indian Evidence Act. The Indian evaluator testifies within this specific statutory ladder and under this specific evidentiary rule, not a generic or textbook-Western frame, and the report should name whichever code actually governs the proceeding rather than reaching by habit for the Act it replaced.

22.6 Currency: testifying after the codes changed

The evidence code and the procedure code that carry these two rules are themselves the products of the recent replacement of the three colonial criminal codes, when the old penal, procedure and evidence Acts gave way to their current successors. The rule that decides which code governs a particular matter - the savings rule that turns, for procedure and evidence, on whether the proceeding was already pending at the changeover - is set out elsewhere in this chapter and is not re-derived here. What the psychiatrist must carry from it is practical: a matter that straddles the transition may be tried under the current procedure and evidence codes even where the offence and its defence are judged by the older penal law, so a report should cite whichever codes actually govern and never assume the newest code applies automatically.

Under the current evidence code, its expert-opinion rule makes the opinion of a specially skilled person a relevant fact whenever the court needs specialised knowledge, and unsoundness of mind is named in its illustrations; the current procedure code, through its classes-of-court provision, fixes the classes of criminal court a psychiatrist testifies before.

6	39
PROCEDURE-CODE SECTION FIXING THE CLASSES OF CRIMINAL COURT	EVIDENCE-CODE SECTION ADMITTING EXPERT OPINION

PITFALL

The recurring real-world error is a currency error, not a clinical one: a psychiatrist swears to or writes a report that grounds the admissibility of the opinion, or names the court, in a section of the Indian Evidence Act or the Code of Criminal Procedure. Those Acts have been replaced. The correct citations are the expert-opinion provision of the current evidence code and the classes-of-court provision of the current procedure code, and using the repealed numbers hands the other side an easy line of attack on an otherwise sound opinion.

23 · Legal aspects of seclusion, restraint and involuntary treatment

Why the marks sit here. Coercion is the point at which psychiatry is most likely to injure the very person it sets out to help, and it is therefore the point at which the law watches most closely. When a patient is shut in a room alone, held down, sedated to control behaviour, or treated over refusal, the ordinary architecture of clinical practice - liberty as the default and treatment by consent - has been suspended. The examiner's interest is not in whether these things ever happen, because they do, but in whether the candidate can say exactly what makes each of them lawful rather than an assault or a wrongful detention. This topic is the legal frame around the three coercive interventions: what the law permits, on what conditions, and with what safeguards attached. The moral reasoning behind that frame, and the rights lens that applies in prisons and custody, are developed elsewhere in this chapter; here the task is the legal skeleton.

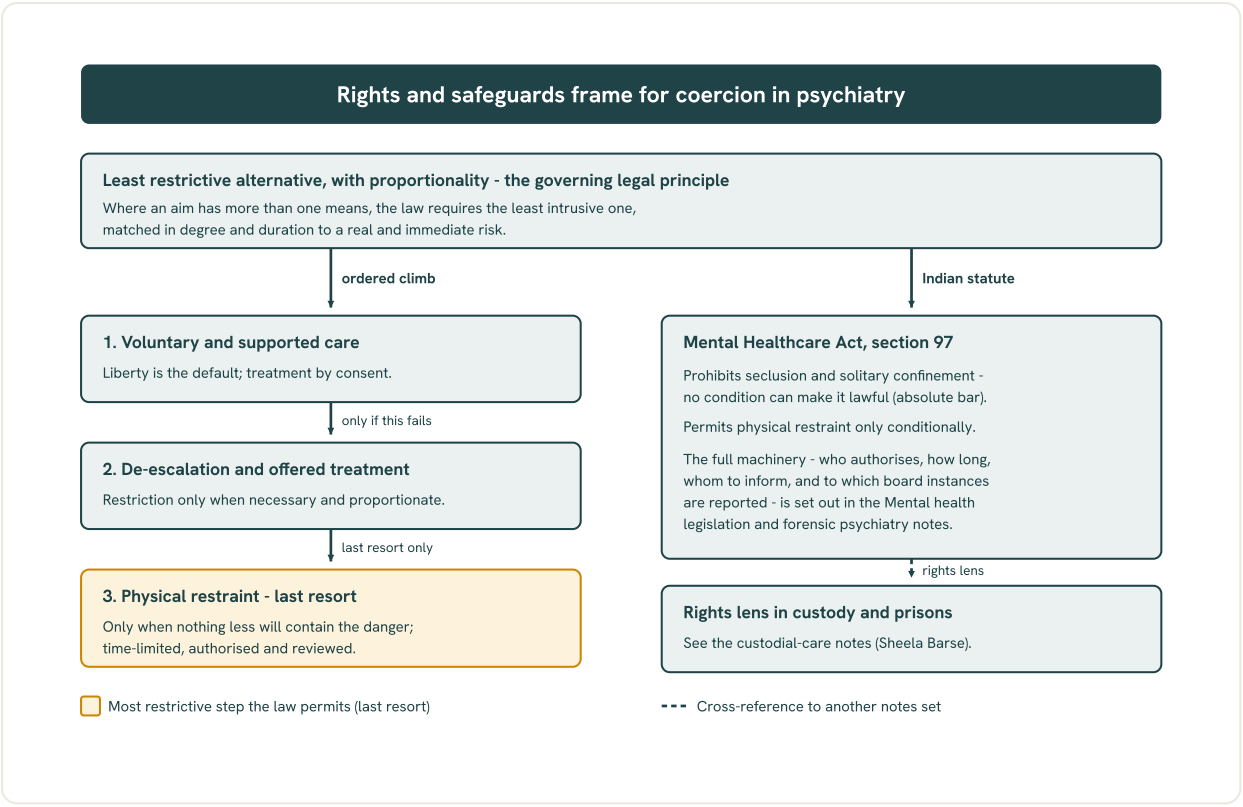

Fig 26.13. The rights-and-safeguards frame for coercion: the least restrictive alternative forces an ordered climb from voluntary care to time-limited, reviewed physical restraint, while Mental Healthcare Act section 97 bars seclusion and solitary confinement outright and permits restraint only conditionally.

23.1 The three coercive interventions and why the law singles them out
